Quetzaltenango, population 30,000, a large portion of whom are
Indians, is the next town in importance to Guatemala.
It stands on the little river Samala, and is a large, well,
and regularly-built place. It contains a spacious church, and six
churches of smaller size, a large town-hall, a plaza, or great
square, with a fountain in the centre, has a daily market,
and is a place of considerable trade. In its vicinity is a hot spring,
which ejects the water to a height of about 30 feet. The
other towns are San Marcos, Tapachula, and Tuxtla.

5. Tolima department, lying north-east of Quetzaltenango; it contains 6,000 square miles, and is
heavily populated; the larger part of the inhabitants are
Indians. The surface is much broken; the climate is temperate
but considerably varied; the soil in the valleys, which are
well watered, produces sugar and coffee. The magueys, herbs,
and vegetables are the chief products of the soil. Sheep
and cattle are largely bred. Lead-mines are wrought by
the Indians in the neighbourhood of Chiasulá. Salt is made from
springs near Yxtiasa. The only town of any importance is
Tocotalcan, which is said to contain 12,000 inhabitants,

Divisions, towns, &c.—Guatemala is divided into seven

wollen cloth, earthenware, and wooden utensils. The other towns are Momostenango, Guetzenetango, and Jascate-

6. Chiquimula, occupies the northern-extreme territory of the republic, on the bordering of the province of Honduras; its area is nearly 6000 square miles; its population about 80,000. The surface is considerably diversified, and in parts very fertile; the climate is healthy, brought about by the Bay of Honduras are hot, moist, and unhealthy. Tobacco, cotton, rice, and sugar are raised largely, with maize, fríjoles, &c. The sugar is grown chiefly for distillation or for making chocolate, a little for exporting drinking rum. The Indians, horses, mules, and cattle are reared in large numbers. The chief town is Chiquimula, population 4500; Acascaugastlan, 3600; Jalapa, 3200; Jilotepeque, 3200; Mita, 3300; Quezaltepeque, 4600; Zacapa, 3000; and the little port town of Yoro, 2000. There are not at present any towns in this province of general knowledge. After the death of his brother John in 1814, he assumed his brother's Christian name in addition to his own. Joseph John Gurney in 1818 became a reog-

7. Vera Pass, the largest of the seven corregimientos, comprehends the projecting tract of country which forms the northern part of the republic; the area is about 11,000 square miles: the population is estimated at 65,000, of whom nine-tenths are Indians. The country is very varied in surface and character of soil: but comparatively very little of it is cultivated. The principal food is corn; and other valuable trees, timber-trees abound; the coffee, cacao, indigo, and nopal plants are said to be indigenous in the forests. In the northern part of Vera Pass is the lake of Peters. The most populous town is Coban, situated in a remarkably fertile valley of the same name; it is inhabited by nearly all Indians, who are industrious and wealthy, possessing fine plantations of sugar-cane, bananas, pimentos, and various kinds of fruit; the other towns are Salsam, population 4500, Coban, 4000; and Rabinal, 6000; but none of them call for specific notice. 

Government, &c.—According to the constitution of the 19th of October, 1851, the executive is confided to a presi-
dent elected by a general assembly, composed of the legis-
lature, which is elected by the people of the republic, members of the supreme court of justice, and the members of the council of state having a deliberative voice. The president is elected for four years, but is eligible to be re-elected. The legislative assembly consists of 59 members. The council of state is composed of the ministers, eight councillors chosen by the legislative assembly, and of others appointed by the president. The revenue and expenditure average somewhat over 400,000 dollars. The debt amounts to 1,300,000 dollars. The army consists of 1000 men, with a patriotic corps and a militia of 5000 men.

The population consists of aboriginal tribes, some of whom live in a state of almost perfect independence, but the main body of the population consists of the descendants of Europeans, and of the mixed offspring of Europeans and Indians, who are known as 'ladinos.' The Roman Catholic is the established religion, and there are few open dissenters. The church is presided over by the Archbishop of Guatemala.

During the Spanish occupancy Central America was termed the kingdom of Guatemala, the city of Guatemala being the capital and seat of Government. During the struggle for independence it remained quiet and subject to Spain; but on the declaration of independence in 1821 it was for awhile united to the Mexican empire of Iturbide. On the publication of the new constitution, July 2nd, 1832, by which the federal system took place, the Province of Guatemala became one of the united states. This union was however after a short time dissolved, and Guatemala then became an independent republic, and has so continued to the present time.

GURNEY, JOSEPH JOHN, was born August 9, 1788, at Earleham Hall, near Norwich, the country residence of his father, John Gurney, who was a member of the Society of Friends, and one of the partners of the Norwich bank. He was the tenth child of eleven children left by Mrs. Gurney at his birth. (See Gurney, Joseph, vol. I.)

Joseph Gurney completed his education at Oxford under a private tutor, without becoming a member of the university, of which however he enjoyed many of the advantages. He acquired the Hebrew and Syriac languages, and was well versed in the vulgar Greek and Latin, and was well acquainted with the principal books of general knowledge. After the death of his brother John in 1814, he assumed his brother's Christian name in addition to his own. Joseph John Gurney in 1818 became a reog-

GURNER, [DEBATE, vol. II., 1842.]
and he saved the Frenchman by Knocking down the Irishman. His prisoner guided him to a tower, where he found the secret government of the French, and several other officers, who had shut themselves up from the now victorious English soldiers. He summoned them to surrender, and the door was unbarred; but Pat Lowe, who had rejoined him, called out, "Dear Mr. Gurwood, they will murder you!" and as he seized the sword when the door was unbarred, a ball from the French sword in his body; but his arm ceased on finding himself seized by the person who had seized him, who added that he was the governor, General Burrié, and that he yielded himself the name of Lord William, with whom he found on the ramparts, who said to him, "Did you take him?" and, on his replying in the affirmative, handed him the governor's sword, which had just been surrendered, with the observation, "Take it, you are the proper person to carry it." The Frenchman granted the privilege when every other officer in the English army wore a regulation sword. From this time he became a noted officer; but though he served with distinction during the rest of the Peninsular war, and at Waterloo, where he received a severe wound, the rank of colonel was the highest that he attained, and he did not become full colonel till 1814.

In 1830 he was placed on the detached list, and shortly afterwards became private secretary to the Duke of Wellington, who was in his service. He died in 1854, and was interred in St. James's Churchyard, Westminster. He was the last survivor of the eight Despatches of Field-Marshal the Duke of Wellington, G.C.B., during his various campaigns in India, Denmark, Portugal, Spain, the Low Countries, and France, from 1799 to 1816, compiled from official documents in France and in possession of Lord William Gurwood. The work extended, with a volume of index, to nineteen volumes; the publication of it occupied the colonel for a series of years, and its popularity was unexpected and unexampled. No collection of official documents of any length had ever found its way into so many libraries and many hands. A second edition was called for, and an abridgment into one volume was issued to satisfy the curiosity of those who did not purchase the complete edition. The colonel had appeared to have been materially raised by the publication, and most of his popularity in later life was based on the "Despatches." Colonel Gurwood used his exertions to give his account of his publications bearing on his military career, but it did not always succeed. The colonel was in the habit of showing his friends a paper by the Duke on the battle of Waterloo, in answer to the observations on the subject by the Prussian general Clausewitz, and was much praised, especially among those who were in the Stem to stem, and was guilty of a breach of confidence. The whole appeared in print in "Fraser's Magazine," as a portion of a review of Captain Siborne's "History of the Battle." The reader who is curious to see what was written on the subject, in February, 1854, and in 1856, will find that he will find it word for word in that magazine for July 1844, without the slightest intimation from whose pen it proceeds—a fact which would indeed never be conjectured by any one perusing the article without previous information as to its authorship. The Duke also supplied to the late Earl of Ellesmere some observations on the battle which are interwoven with his article on Alison's "History of the War," in the "Quarterly Review." In return for the colonel's services the Duke appointed him Deputy-Governor of the Tower of London. He again visited Spain in company with Lord Eliot, the present Earl of St. Germans, to endeavour to mitigate the cruelties of the civil war between the Carlists and Carlistos, in which neither party gave quarter; and their mission was partially successful.

From the time of the publication of some portions of Napier's "History of the Peninsular War" in 1840, Colonel Gurwood was involved in a disagreeable controversy respecting the circumstances of the capture of the British fleet by the Russian fleet at the Cape of Trafalgar, who had commanded one of the storming parties, made a statement in October 1838 to the effect that he (the major) had accepted the surrender of the ship; that a sword, after it had been given, was presented to him in token of surrender; and while he was engaged with two officers who held him for protection, one on each arm, Lieutenant Gurwood came up and obtained the sword of the governor; on seeing him present which on the ramparts, the major, according to his own account, "turned on his heel and left the spot." The major died in 1839, and this statement was made public in the following year in a second edition of that portion of Napier's work which the people of North Africa, the first, having stated that "Mr. Gurwood, who though wounded had been amongst the foremost at the lesser breach, received the governor's sword." Colonel Gurwood had been in garrison with the major in 1834 at Portsmouth, and always wore the sword when the major, his sword; but the colonel had not produced any remark from that officer. A long and vexatious discussion ensued on the point, which was brought to a close by a very singular incident. Gurwood did not know the name of the French officer whom he had rescued from Pat Lowe, and when evidence would have been important to show the justice of his claims, as the Frenchman had guided the Englishman to the tower where the governor was found, and witnessed what then took place. The major, turning over the years in 1844, the colonel found a letter addressed to Lord Wellington in 1815 by a captive French officer named Bonfili, who might, he inferred, be the person he was in search of. He made inquiries in Paris to ascertain if M. Bonfili was still alive, found that he was, wrote to him, and received a letter dated the 1st of May 1844, in which M. Bonfili informed him that he was indeed the officer whose life he had saved, and gave a statement of all that he remembered of the night of the storm, which corresponded partially with facts mentioned in the Despatches of the colonel, but in all essential points confirmed his statement, and was irreconcilable with that of the major. The colonel read it with feelings which he declared it impossible to describe. He visited M. Bonfili at his residence in the Faubourg St. Honoré, and he was a very singular affair in a pamphlet, of which he printed only fifty copies for private circulation, from one of which these particulars are taken. The preface is dated on the 14th of June 1845, and was his last literary effort. On the 30th of December in the same year, in a letter to the colonel, he attributed at the inquest to the effects of the wound which he had received so many years before at Ciudad Rodrigo, he terminated his life by his own hand at Brighton, leaving a widow, the Frenchman and three children.

GUTTA PERCHA. [ISABEILLA, S. 2.]

GUYON, GENERAL RICHARD DEBAUFRÉ, was born March 31, 1813, at Walcot, near Bath, Somersetshire, in which city he received his early education. His grandfather was a captain in the Dragon Guards; his father, John Guyon, of Richmond, Surrey, was a commander in the royal navy, and died in 1844. Richard Guyon was intended for the army, and at an early age held a commission in the army at the Surgeon-General of the military department of the army, and was appointed aide-de-camp to Field-Marshal Baron Speney, commander of the Hungarian life-guard. In 1836 he received the degree of major in the army, and in 1841 he was promoted to the rank of colonel; and soon afterwards retired to the neighbourhood of Pesth, where his wife's relations resided, and where he spent his time in country occupations and field-sports.

In September, 1849, when Jellachich, the Duke of Carinthia, invaded Hungary, Guyon offered his services to the Hungarian diet, and received the appointment of Major of the Honveds, or national guards. On the 20th of September he contributed materially to the defeat of Jellachich at Sukořo. In the battle of Schwechat, near Vienna, on October 20th, Major Guyon with his raw troops achieved at Mannswhor the only successes of that disastrous day, when, his horse having been shot under him, he led his men to the charge on foot, and armed them with the muskets of the slain Austrians, in place of the scythes with which many of them had fought. He was rewarded by being raised to the rank of Colonel on the field of battle. He was afterwards raised to the rank of General at Debrecin. He commanded the rear of Gőrő's army on the march from Pesth to Upper Hungary; and at Ipolyangy (January 10, 1849), by a daring and skilful effort saved the baggage from the pursuing Ausrians. On the 5th of February, with 10,000 Hungarians, he stormed the defiles and heights of Branyisko, defended Pesth with 35,000 Austrians, and reduced the enemy's cannon and baggage to a large amount, and cleared the way for the van of the army to pass, Gőrő having vainly attempted to turn the defiles by a flank movement. At the battle of Kapolna (February 28th) he was mortally wounded. On the 31st of April he entered the fortress of Komorn with a small body of troops, though it...
was the closely besiegued by the Austrian troops, and
announced to the despairing garrison the approach of Gőrgei
with a relieving army. When Gőrgei was appointed minis-
ter of war, General Geyon for a time performed the duties of
the office, in order to enable Gőrgei to retain his command-
in-chief. On the 6th of August the Austrians and Hungarian
armies met in battle, whereafter, during the night, Gőrgei
and his horsemen could not save the Hungarian army
from a defeat. On the 11th of August Kosuth resigned his
office of governor, and named Gőrgei dictator, who on the 17th of
August forced the war by a general surrender.
Geyon, Bem, Dembinski, Knyet, and other officers who
had not been included in the surrender, made their escape
with much difficulty to Turkey, where, in defiance of the
conjoint demand of Austria and Russia, they were protected by
residing in prison. The time at Gőrgei was taken by the
Stantinopeleli by his wife, whose property in Hungary had been
confiscated by the Austrian government. He was offered and
accepted service under the Turkish government; and though
he decided resolutely to become a Mohammedan, was sent
by Damascus with the rank of lieutenant-general on the staff,
and with the title of Kourschid Pasha. In November 1803
he was directed to proceed from Damascus to the army in Asia
Minor, and reached Kars by a series of rapid journeys. There he
became a member of the chief of the military council, but without any real
command over an army of 15,000 undisciplined troops under twenty-one pashas,
each with the rank of a general. He was allowed, however,
to organize the army and to construct defences. That organi-
sation was consummated, though doubtless too hastily. He
immediately afterwards by General Williams and his officers, became a
basis for the heroic defence of Kars. He died of cholera,
October 14th, 1856, at Constantinople, and was interred
with the honour of a general at Constantinople.
(General Geyon on the Battle-Field of Hungary and Asia, by Arthur Kinglake.)

GWILT, GEORGE, architect, was well known as an anti-
quary, and for his restoration of the choir and tower, and the Library of St. Mary Overy's church, the parish church of St. Saviour's, Southwark. George Gwilt and Joseph Gwilt were the sons of George Gwilt, an architect, resident in the parish, who was surveyor for the county of Surrey, and who erected amongst other buildings, Horsemonder Lane Goul and Newington Sessions House. He died on the 9th of December 1807. George Gwilt, the elder of the sons, was born on the 8th of February 1775. He was sent to a school at Hammersmith, but was indebted for his general education mainly to his own exertions. His professional knowledge was acquired in the office of his father, whom he succeeded in practice. Prior to this however, Gwilt junior had com-
missioned his own professional course with the building, about the
year 1801, of the warehouses of the West India Docks. He
had a very marked taste for modern architecture, and of art, of which he at length got together, at his house in Union
Street, an important collection, many of the remains being found in St. Saviour's. In 1816 he was elected a Fellow of the Society of Antiquaries. In March and June of that year he
had valuable communications by him, on the remains of Win-
chester Palace, Southwark, appeared in the 'Gentleman's Magazine';
and he contributed occasionally at other times to the
same journal. In 1816 he was engaged upon the resto-
arion of the steeple of Bow Church, a work which required
much professional skill, and which he performed with strict
regard to the preservation of Wren's design. The peristyle of
columns and the obelisk had to be removed and rebuilt,
and were completed on the 11th of July 1818, when the copper vane (in the forms of a dragon) that of those long, was fixed. Very soon afterwards, the foundations of the
same church being found defective, some important works
for their maintenance were carried out under Gwilt's super-
vision; and during these works the interesting relic
remains of the original building were identified, and were
described by him to the Society of Antiquaries in June 1858,
in a paper under the title of 'Observations on the Church of St. Michael, Bow.' The beauty relating to its Original Structure,' and which paper was afterwards printed in the 'Vetusta Monumenta,' vol. 5. The restoration of the
choir and tower of St. Mary Overy's church was commenced
about the year 1826, and was completed in about two years,
with the addition of two practical skills in Italy, and we
find little to say of him till the year 1838, when the
Lady Chapel of the church last mentioned being rescued
from destruction, he undertook the direction of the restoration
without remuneration, and completed it in 1838, with the
skill which he had exhibited in the other part of the church.
Joseph Gwilt lived to the advanced age of eighty-one, occupied
in his favourite pursuits till within a few days before his
death. He had however suffered long from a painful com-
plaint, and the loss of his wife in 1832, very much depressed
him. He died on the 27th of June 1856, and was buried in the
family vault, next the choir of St. Mary Overy's Church.

JOSEPH Gwilt, the younger brother of George Gwilt, is also
mentioned, and the author of several valuable works on
architectural

GYMNARCHUS, a genus of Malacocephalous Aposei fists. The body is long and slender; the gill opening before the pectoral fins; dorsal fins running the whole length of the body, and having an attached and conical spine, a very small, with a single row of cutting teeth. G. Nitidus is the only
species; it inhabits the Nile.

GYMNEMA, a genus of plants belonging to the natural order
Asclepiadae. It has a sub-ureticulate, thorn-like, usually curved,
and glance body or fleshy tuft at the base of each filament.

G. acutiforum, Cow-Plant, or Milk-bearing Gymnema, has an
erect stem, or rather twining; the leaves are on short
stipules, broader, and acuminately, usually with several spurs;
the umbels many-flowered, shorter than the pedicels; the
throb of the corolla crowned by five fleshy tubercles; the
tube furnished with double pilose lines running from the
tubercles. It is a native of Ceylon, where the milk of the
plant is used to substitute for cow's milk, and the leaves
are boiled with food.

G. tingenae is a native of Peru. It has a twining slender
stem, coriace leaves, acuminate to ovate; the umbels or
corymbos often twin, at first shorter than the pedicels, and
in length gradually elongated, the glands of the filament
are shorter than the stamens; follicles cylindrical, spout-
shaped; stigma simple, oval, mucit, crowning the tube of
the corolla, and therefore exceeding the stamens. The
flowers are large, numerous, and of a pale-yellow color.
The calyx 5-cleft to the base. From the leaves of this
plant a green dye is prepared by the Bemese. Seventeen
species of this genus are enumerated, none of them of any
particular interest.

(Gymnoglossum; Don. Diclioglossa Planta)

GYMNÉTRUS, a genus of Fisthas belonging to
the group of Riband-Shaped Asclepiapogus.

This has the following characters.—Body elongated, compressed; a single
dorsal fin extending the whole length of the back; ventral
sucking each of a single ray, only sometimes slightly and
dilated at the end; no anal fin; teeth pointed, small.

The species of this genus have very rarely been obtained entire.
They have generally been taken dead, and consequently
have been crushed and mutilated. Of the species of this
genus, Mr. Yarrell says, "three probably belong to the
Mediterranean, two to the seas of the North of Europe,
and two to India. One northern species, besides one of those
apparently belonging to India, has been taken on the
coast of New Holland, and there are more than once in Scotland: that of India, once on the coast of Cornwall."

G. Hawkerti (Bloth), Hauken's Gymnus, the Oval
Gymnus, the Cell Conil of Cornwall. This species has
been taken in Corwall. This species has been
drawn up by Mr. Couch from a drawing and notes of
a specimen taken in a net at Mount's Bay in 1791—••••••••••
The length without the extremity of the tail, which was
w. 8 9 feet; the depth, 10 inches; thickness, 9 inches;
width, 3 inches; with six spines on the back, short and
slender; eye large; pectoral fin round; no anal fin; the
dorsal fin reaches from above the eye to the tail. The
ventral fins are formed of four long processes, proceeding from the
rear end of the fish, in a fan-like manner. Gwilt with
the base is purple, the pectoral, crimson. The back and belly
are dusky-green; the sides whitish; the whole varied with clods
and spots of a darker green; the fins crimson." A very fine
HADLIGH. [Scot.]  
HEMATURE. [Thinus, Organic, S. 1]  
HEMATURE, a name given to certain forms of the native Peroxide of Iron. When of a red colour it is called Red Hematite; and when brown, Brown Hemitite. [Lat.]

HAILSHAM. [Snefr.]  
HAIR. [Thinus, Organic, S. 1]  
HALDANE, JAMES ALEXANDER, son of Captain James Haldane of Glenegies, Perthshire, was born at Dundee, on the 14th of July, 1765, within a fortnight after his father's death. In many respects his career was a counterpart of that of his elder brother Robert. In 1777 he accompanied his brother to the High School of Edinburgh, and subsequently pursued his studies at the university. Declining a partnership which was offered him in connection with Messrs. Coutts's Bank, London, he entered in 1786 the East India Company's naval service. In 1793 he obtained the command of the Melville Castle, East Indiaman. In September of that year he married the only daughter of Major Joss, of Culsenard, in the county of Haafs. At the close of this year he succeeded by his courage and presence of mind in quelling a mutiny which broke out in a ship which had been ordered to winter quiet, till winter and the end of the season, and which was beginning to assume an alarming app-reance. His views on religious matters becoming more decided, he at length resolved on retiring from the sea. Early in 1794 he rejoined his wife in Scotland. Soon afterwards he took up his residence in Edinburgh, where he became a member of the Free Church of Scotland, and was interested in various efforts for the religious instruction of the people. He took a leading part in the preaching tours which were undertaken through various parts of Scotland, in the establishment of Sunday Schools, and other Christian efforts. In December 1797, the Society for propagating the Gospel at Home was instituted. In February 1798, Mr. James Haldane became the first pastor of the Tabernacle or Circus Church. In May 1801 the congregation build a new Tabernacle, built at the head of Leith Walk, at the entire cost of Mr. Robert Haldane. In 1808 Mr. James Haldane having changed his views with respect to Infant Baptism, although he left the communion open to parties who might differ in their views on this question, many of the members of his church left. Mr. Haldane continued minister here till his death, which took place on the 8th of February 1861. Mr. Haldane published numerous pamphlets on subjects which at the time excited attention in the religious world; and found his largest sale in the Union, on which he works on 'The Doctrine of the Atonement;' 'On Christian Union,' his Exposition of the Epistle to the Galatians;' and 'Views of Social Worship.' Some of his pamphlets were directed against the opinions of the Trinitarians.

HALES OWEN, Worcestershire, a market-town and borough, in the parish of Hales Owen, is situated in 53° 32' N. lat., 3° 8' W. long., distant 36 miles S.E. by E. from Bewdley, 117 from Worcester, and 16 from the sea. The population of the borough of Hales Owen in 1861 was 3412. The living is a vicarage in the archdeaconry and diocese of Worcester.

The town of Hales Owen is pleasantly situated in a valley, and contains many good houses. The parish church is a fine building, with a handsome spire, supported by four arches. The Independent, Baptist, and Wesleyan Methodists have chapels. In Hales Owen are a Free School,
founded about 1682, which has an income of above 100l. a
year, and had 60 scholars in 1683; National Schools, and
an Infant School. Nails and hardware are extensively
made. The market-day is Monday; fairs are held on
Easter Monday and Whitsunday. Some remains exist of
an old castle called Capenhurst. It was built by King
John. Near Halés Owen is the Leasanws, the birth-
place and residence of the poet Shesnten, and the grounds
of which were arranged by him. Shesnten was buried in
Halés Owen churchyard, and the church contains a monu-
ment to him.

HALÉSWORTH. [SUFFOLK.]
HALIBUT, OR HOLIBUT. [HIPPOLOUSIS].
HALOSCIAS (Fries), a genus of Plants belonging to the
natural order Umbelliferae, and the tribe Scitellae. It
contains a species, A. ambrosioides, with a scapose
inflorescence, and a small umbelliferous fruit; and less
commonly described as A. dracunculus, with an
inflexed lobe and short claw; the fruit elliptical, terete,
or slightly dorsally compressed; carpels with five sharp
somewhat winged ridges; interstices and commissure with
many vittae; seed not cohering to the carpel, without vittae.
One species of this genus is a native of Great Britain.

H. Scoticum, Scottish Lovage, is found on rocks on the
seacoast of Scotland and Northumberland. It has a her-
beaucoup stem, tinged with red, from 18 to 18 inches high.

HAL-FIR.
HALTWISTLE. [NORTHUMBERLAND.]
HAMILTON. [CANADA, S.]
HAMILTON, SIR WILLIAM, as head of the old family
of Hamilton of Preston, in Haddingtonshire, in'heritor
of a baronetcy created in 1673, but for many years
dormant. He was born on the 8th of March, 1788, in Glasgow,
where his father, Dr. Hamilton, was a professor in the university;
and there he received the earlier part of his academical education.
The length of exhibitions and other circumstances long had a
been a great source for the more distinguished among the
Glascow students: Adam Smith, among others, owed his
English education to it. As a Smaller exhibition Hamilton
got to Oxford; and he took his degree with honours as a
first-class man, printed after a long and arduous
in 1813 he was admitted a member of the Scottish bar.
But law, except the Roman, did not receive much of his
attention; and the only practice he ever had was the very
little which became incident on him, will in, after some
years, he was appointed Crown solicitor of teinds or tithes.
Even while a very young man, he had acquired no small part of
his singular and varied stock of knowledge; and mental
philosophy began early to be his favourite pursuit. On the
death of Thomas Brown, in 1820, he stood for the professor-
ship of Moral Philosophy in the University of Edinburgh:
but Mr. Wilson was the successful candidate. Next year,
on the nomination of the bar, he became Professor of Uni-
versal History, the name univ'rous in his appointm'nt,
little more than nominal in respect of engagements, was
hardly better as to the performance of duty. The depart-
ment is not in any way imperative on students: and it never
carved single pupils, unless for a while under the elder Tyler.
Sir W. was rough without rich, and his life was con-
sumed in professional drudgery, was left undisturbed and
undiverted, to the prosecution of his studies and speculations. It
was long after these before fruits visible to any but his immediate
friends. For the digesting of his thoughts he was nearly as
independent of necessity of writing, as his iron memory
made it necessary to the preservation of his knowledge;
and the hardy, he seems to have long shrunk from the toil of despera-
ting to extend ideas, for which he did not hope to find an
apt and ready mind to appreciate. It was only, as he himself
declared, on the pressing request of the editor of the
'Edinburgh Review,' that he was induced, in 1839, to give
to that periodical the first of a series of contributions, which
closed 1839, and which unfortunately constitutes as yet
by much the larger proportion of his published writings.
These papers exhibit the variety of his learning not less than
its depth; and the philosophical essays, which were among them
speedily found readers, who, if few, were competent to
do them justice.

In 1836 he found his right place: he was appointed by the
town council of Edinburgh, though not without a con-
test, to be Professor of Logic and Metaphysics in the
University. He was, very few of the Scottish professors
holding offices thus designated, but there was none in both a
the spheres indicated by the official title. The vague term
which stands second, opened up to him in his teaching any
walk he might choose to tread in the vast field of mental
philosophy, of which he had probably in his studies traversed
more than any other man them or now alive. The first title
pointed his way to one special mental science, which he had
studied in all its existing shapes, and which he now set about
systematizing in harmony with new lights that had dawned
on his own mind. In the current of his practice, of combining the whole matter of his instructions
into one course of lectures, to be delivered in one and the
same session (a term of six months in each year), he lectured
alternately in the one named section and in the other—the
Letters and Metaphysics; the next year he declined to
the gratification of debating, after a whimsical squabble,
an attempt of the town council, who are the legal administra-
tion of that university, to force him into the common practice.
His reputation and influence required that he should take
an active part in the discussions of the Lothian Club, which
had become celebrated in the learned circles of Germany,
in Germany, and had begun to be known and esti-
mated by many at home: the most eminent foreign thinkers
had concurred with not a few of our own, in pressing emin-
cently the extraordinary gift of his claim to the Logic chair;
and in England, as well as in Scotland, philosophical speculators
discovered more and more plainly that, in those fragmentary
treatises of his, there had been opened veins of thought which
think men durst not leave untied. His teaching, again,
not only lent itself with ease and ardour to the multifarious
gathered round him in his lecture-room. There is no evi-
dence indeed that his logical lectures have as yet had much
effect on his personal pupils. But the metaphysical lectures
excited a keen interest in the more advanced students who
were qualified for severe abstract thinking; while they
guided the thinking of not a few to channels in which it
long or always continued to flow. He was, too, not too
anxious in encouraging and directing for the young men who
philosophized as well as he, and in teaching them to
awake philosophical reflection and reasoning.

Sir William's studies seem to have been conducted,
thenceforth, with a steadier view than before to systematic
exposition and publication. Still the labour proceeded slowly.
And the larger part of the years which followed the
controversies, were somewhat too apt to interrupt the progress
of one who was armed for warfare less ignoble. Among
other things, he, himself a Presbyterian, published a pamphlet on
the Reformed Church which was printed in 1837. It was
genius to publish the 'firmament of Scottism.' Very soon,
and, afterwards, he became the vice-president of the
college. In 1837 or 1838, he was made a member of the
college. In 1841, he was made a member of the
parliamentary house, and was afterwards able to
parlamentary house, and was afterwards able to
parlamentary house, and was afterwards able to
parlamentary house, and was afterwards able to
parlamentary house, and was afterwards able to
parlamentary house, and was afterwards able to
his own doctrines which he had there promulgated, but in a tribute to the memory of another of his celebrated masters, from whom he had neither derived, nor professed to derive, much if anything in his own opinions. He undertook to edit, with notes, the collected works of Degauld Stewart. The work for that purpose began in 1836, is still uncompleted; and nothing has appeared of the biographical introduction which he intended to deduce it. In 1866, when in country-quarters, Sir William suffered fracture of a limb; and he died in Edinburgh on the 6th of May, 1866. He has left a widow and family. The name of Mugran rather than Sir William is to be in such a state, that they may easily be prepared for the press.

As those who knew Sir William Hamilton through his writings only, cannot do full justice to the multifariousness of his character, it is to the details of his writings which had personal bearings, will do positive injustice to the real likeness of his personal character. He was undoubtedly a stern, and keen, and often eager controversialist, occasionally a hasty one; in debate never beat about for smooth words; and, absorbed in his love for science and learning, sometimes forgot to be gentle towards those whom he thought to be erring or knew to be comparatively ignorant. He was watchfully jealous also of the attempt to exclude his name from the register of the Royal Society of Edinburgh, which was a form of the combative tendency, moreover, there lay great generosity, great kindliness and warmth of heart; he was invariably amiable when occasion did not force on polemics: he was an added trait, a worthy friend, beloved as well as esteemed by those who were admitted to his friendship.

About his erudition there cannot well be two opinions among those who have had opportunities and competency for judging. His mere mass was a thing extraordinary: it was a mass, and a mass which the great profusion of accurate scholarship; it spread over tracts of reading the most obscure and neglected; and it was, everywhere, the real knowledge of a thinking man, not the word-cramming of a pedant. His range embraced all the great divisions of knowledge, except mechanics and physical science; while here, too, it did not exclude anatomy, with physiology and some other branches of medicine. He was a thorough linguist in the classical tongues, and in German. With as little as possible of the poetical temperament, he was well read in the great poets; and his historical information was unusually extensive. In philosophy he was familiar with the Greek writers one and all: Aristotle and his commentators he had probably studied more extensively and profusely than any of his predecessors. He knew the whole course of the scholastic philosophy, as no man else has ever known it since the middle ages departed. With British systems it is needless to say that he was familiar. His friend, beloved as well as esteemed by those who were admitted to his friendship—

As to his originality, this question may be put: not whether Hamilton was the most original of philosophers; but whether there has ever been any philosopher who, learning even half as great as his, united so much of real and active originality as a thinker. In the treatment of details he has a favourite manner, which often disguises his independence. He is perhaps not too sparing in the use of even the most hackneyed phrases. As if the best way of discovering philosophical truths were by deciphering them in some medieval text through the dust of centuries. He takes a pride in quietly following on some schoolman or other a doctrine of argument which many men would have been too glad to take credit for as their own; and sometimes, half-hidden in a brief note, there is given, as an obvious and matter-of-course comment on a scholastic brocad or term, some assertion which proves on closer examination to presuppose a wide process of new inference. The outlines, however, of those sections in his own philosophical creed which he has taken the trouble to expound, are laid down broadly enough to let their character be seen. Baron von Humboldt, who valued or worthless, they are at least his own,—as much his own as very many systems which all of us rightly admit to be essentially novel,—as much his own, it may be said, as any system of philosophical opinions can be, unless it ignores everything that great thinkers have ever thought before.

What may be the correctness, and what the value, of his peculiar opinions, is a question on which, if it were to be adjudged at present, contradictory verdicts would be given. Probably no one will be competent to decide it justly, till there has taken place a long time of great interreligious discussions, which travel in a track, not only at several points new in itself, but likewise, everywhere, little familiar to most thinkers in this country. Hamilton's writings are Ger- manic rather than national. They are in a language in freedom with which he has taken German doctrines and methods (with a large admixture of Scholasticism) as materials to be distilled in his own alembic. The exotic character is observable, both in his highly speculative aims, and in his severe ex- pression. The richness of his speculations is, in a certain respect, characteristic: it is distinctly alien to the broadly practical English mind; and the latter is one which has never, before him at least, been made to take root in the philosophic mind of Scotland. Nor can his criticism be free from pain. He never cares for doing more than saying what he thinks, and to be worth saying—saying it unequivocally, and saying it in the smallest number of words that is consistent with safety. He will not turn aside to amuse us; he will not hurry or disguise to excite us; and he is not a writer of an easy, precise, dry, writer. But for such as will take the trouble to follow his course of thought, and reflect on its contents, there are perhaps no philosophical discussions, certainly none of our times, that are so suggestive of processes of thought—processes which are not confined in direction, and lofty in design and in possible result.

Of Hamilton's Psychological and Metaphysical doctrines, nothing special requires to be said. They are before us, in certain parts, in his own exposition; and that they have been much discussed, and have in some quarters excited a powerful influence on speculation, is a good omen for philosophy. We have, especially, his treatment of three great problems in philosophy. First, there is his theory of the two kinds of thought—real and formal. Secondly, there is a special application of this theory to the construction of a theory of External Perception. Thirdly, there is an exhaustive system of Metaphysics Proper, or Ontology, in his 'Philosophy of the Conditioned,' or 'Conditions of the Thinker's-acts and noble ideas,' traced out for us, as yet, in nothing but a tantalising fragment.

Regarding his Logical system, our public information is still very unsatisfactory. It is to be gathered from an appendix to his 'Discussions,' and an authorised but meagre publication from lectures, Bayes's 'New Analytic.' These materials will probably convey no distinct notion of the system, unless to readers who are familiar with the German methods of logical analysis since Kant. The leading points may be briefly set out, and then left to be briefly set out, to persons acquainted with the outlines of the science in its received forms. 1. Hamilton insists on having, in all propositions through common terms which are set forth for logical discussion, not only a thought, but a sentence in a certain form, argue as do as to subject. The point, though merely one of form, is curiously suggestive of difficulties, and hence of solutions. 2. Instead of recognizing only four forms of propositions, the A, E, I, O, of the old logicians, he insists on admitting all the eight forms which are possible. (See Thomson and Scler.) 3. He widens the range of the syllogism, by admitting all moods which can validly be constructed by any combination of any of his eight kinds of propositions. 4. The syllogisms are not held to be intelligible, but only, by the extension and comprehension of terms, is worked out by him in its reference to the syllogism. This application of the doctrine has certainly not been anticipated by any logician; and, when elaborated to its results, it throws many new lights on the character and mutual relations of the syllogistic figures.

HAMMER-PUROSTALL, JOSEPH, BARON VON, was born in 1774 at Gratz in Styria, where his father held a respectable post under the Austrian government. He was educated at the Prussian Polytechnic school in Berlin, and transferred to the higher mechanical academy established by Prince Kaunitz. After having taken a part in the compilation of Meninski's Arabian, Persian, and Turkish Lexicon, he was appointed in 1796 secretary to the Prussian ambassador at Constantinople, and was afterwards sent as minister for foreign affairs. While in this employment he translated a Turkish poem on the Last Judgment, and supplied several other poems to Wieland's 'Deutschem Mercur.' In
1799 he was attached to the embassy of the learned Baron von Herbert at Constantinople, which sent him with one of the imperial consuls on an important errand to Egypt, where he procured for the imperial library some mummies of the ibis, hissing cats, and other, strange, Arabic manuscripts, and other rarities. As interpreter and secretary he made the campaign in Egypt under Hutchinson, Sir Sidney Smith, and Joseph Pacha, against Menou, and in the autumn of 1801 proceeded by Malta and Gibraltar to England. In 1802 he accompanied, in August, the Austrian ambassador, the Baron von Stürmer, as secretary of legation to Constantinople. In 1806 he was appointed consular-agent in Moldavia. In 1807 he was appointed to the See of Yannina; in 1811 he was appointed a state counsellor, and appointed court and state interpreter; in 1817 promoted to be imperial privy counsellor; and in 1846 created a baron, after having succeeded to the estates of the Countess von Purtschall. In 1815 he had occupied himself earnestly in procuring the restoration of the Oriental manuscripts and other treasures which had been removed from the Vienna library to Paris by Denon, during the occupation of Vienna by the French in 1809. In 1847, continuing to be in the active service of the Department of foreign affairs as counsellor extraordinary, he was chosen president of the newly instituted academy, which he resigned after holding the office for two years. His intervals of leisure from business were spent at his castle of Hainfeld in Syria, where he laboured on his very numerous literary and historical works. He died on the 15th of November, 1849.

His works are extremely numerous, and those of a historical character highly valuable. His publications of Turkish, Arabic, and Persian poems are in many instances interesting to the general reader, but his philological knowledge was not sufficiently indicated to the student. Among the more noticeable of his historical works are 'The Trumpet of the Holy War,' 1806; 'The Constitution and Government of the Ottoman State,' 1816; 'Glances upon a Journey in 1804, from Constantinople to Brousse and Olympus, and thence by Nicca and Nicomedia,' 1818; 'History of the Assassins, from Eastern Sources,' 1816, a work which has been translated into English by Mr. Wood; 'Constantinople and the Bosphorus, together with a complete and detailed description of the city,' 2 vols., 1818, 'History of the Ottoman Empire,' in ten volumes, 1837-1834, an excellent work, of which several editions have been published; 'The Government under the Khilifas,' 1836; 'Picture Gallery of the great Muselman Commanders, with Memoirs,' in six volumes, 1837-39; 'History of the Golden Horde of Kiptchak, that is, of the Mongols in Russia,' 1840; 'History of the Ikhane, that is, of the Mongols in Persia,' 1844-45. All these works are remarkable for the accuracy of the information, the correctness of the history and present state of the East. Of his other productions we may mention, 'Scherin,' a Persian poem, 1800; his translation of the 'Divan,' of Hafi, from the Persian, 1813; his translation of the 'Nasir-ol-Molk,' 700 Poets, 1818; 'The Eastern Troilof,' from Persian, Arab, Persian, and Turkish sources, 1818; 'The String of Jewels,' from Abul-Maass, 1823; a translation of the Arabic lyrical poet Motensub, 1823; a translation from the lyrical poems of Baki, 1824; a 'History of Turkish Poetry,' with selections from 2000 poets; Fasi's allegorical Turkish Epic of the Rose and Nightingale, 1834; Samaschari's Arabic poem of the 'Golden Necklace,' 1835; Mahmud Scheibserder's didactic poem, 'The Rose-Blow of Secrets,' 1836; 'The Falconer,' an old Persian didactic poem on the art of hunting, 1840; and a 'History of Arabian Literature,' in three volumes, 1850-52. He has also written a volume 'Mammon's Drick-lang,' (Mammon's Trial), containing an Indian pastoral, a Persian opera, and a Turkish comedy. For his translations of the 'Contemplations of Marcus Aurelius,' into Persian, published in 1831, he was rewarded by the Shah with the order of the Sun and Lion. In 1810 he established a periodical called the 'Oriental,' to which he contributed much, and in which he developed a new style of Persian poetry, which was continued till 1819; and he was a frequent contributor to the 'Jahrbücher für Literatur' (Year-Books for Literature), and to other periodical works. 

HARBURG, a sea-port town in the kingdom of Hanover, province of Lüneburg, is situated on the left bank of the southern arm of the Elbe, opposite Hamburg, 106 miles by railway from the city of Hanover, and has about 6000 inhabitants. It is surrounded by walls, and defended by a citadel, which also commands the passage of the Elbe. There are two churches, an hospital, a gunpowder factory, sugar refineries, tanneries; manufactories of woolen stuffs, linen, and cotton. The town formerly belonged to Hamburg or Altona and brought thence to Harburg, in lights; but simultaneously with the construction of the railway from Hanover to Harburg (which, it may be added, connects the port with all the principal towns of Germany), the town has been enlarged and so as to afford accommodation for 500 vessels, which may now land their cargoes on the wharfs. The depth of the channel between Harburg and Altona is 10 feet at low and 15 feet at high water. The port extends to the railway goods-station, and merchandise is lifted by means of the hold of vessels and placed on the train. The improvement of the harbour, the completion of the railway, and the declaration of the freedom of the harbour in 1850 gave a great impetus to the commerce of Hanzburg, which continues to improve, although the freedom of the port was suppressed in 1853 by the commercial treaty with Austria and Prussia. The distance to Hamburg across the Elbe is four miles and a half.

HARDINGE, HENRY, VISCOUNT, third son of the late Lord Plassey, of Hambly Wide, near Ashford, co. Durham, by Frances, daughter of James Best, Esq., of Chatham, was born at Wrotham, Kent, on the 30th of March, 1785. He was a member of a family which has long been located at King's Newton Hall, Derbyshire, and is said to have been related to the King of the Scots, while in possession of the Duchy of Cambridge. Having spent a short time at Eton, Henry Hardinge was gazetted ensign in a regiment of foot, October 6, 1798, obtained his lieutenancy in 1800, and captaincy in 1804. It was as his good fortune early to be selected for the service of the Duke of Wellington, then Sir Arthur Wellesley, under whom he served throughout the whole of the Peninsula War, and for a considerable time was upon the staff of the commander-in-chief; he was also for nearly the entire period deputised to consult with Sir John Moore in the field. He was present at the battles of Roliça and Vimiera, where he was severely wounded; at the battle of Corunna he was by the side of the gallant Sir John Moore when he received his fatal wound. After having lost his hand at Corunna, he was present at the passage of the Douro, the battle of Buceso, the lines of Torres Vedras, and the battle of Albuera. In this engagement he displayed the greatest skill, courage, and self-command; it was a hard-fought field; and to the change in the face of the enemy a considerable part was due to the brave and excellent service of his division. The influence of the British infantry, Lord Hardinge often pointed back in after life as having encouraged him as a general to persevere through every obstacle, and to place perfect confidence in the enduring value of British troops. After this he found himself in a stronger position with the Wellington troops, and was engaged in every engagement of the war. He took part in the first and second sieges of Badajos, at Salamanca, and at Vittoria, where he was again severely wounded, and also at Pampeluna, at the battles of the Pyrenees, and at Nivelle, Nivernais, and Orthes. When he returned to England after the close of the Peninsula War, he was justly regarded as one of the most gallant officers in the service. Upon the renewal of hostilities he was again in arms, and took an active part in the campaign of 1814 under the Duke of Wellington, whose staff he then was serving. Two days before the battle of Waterloo he was employed as a brigadier-general with the Prussian army at Ligny, where, in a skirmish with the enemy, he was wounded in the left arm, which he had to be immediately amputated, and prevented him from taking a personal part in that glorious victory. He was however rewarded with the dignity of K.C.B. on the enlargement of the order of the Bath in the same year, and with a pension of 200l. a year. On the death of Sir Wellesley Selby, he was made a member of the privy council, and two years later exchanged this position for that of the chief secretarieship for Ireland, under the late Duke of Northumberland as lord lieutenant. Here however he did not remain long; the Duke's ministry
retired from office in the autumn of the same year, and Sir Henry Hardinge returned to England. He resumed his high post however under the short-lived ministry of the late Sir Robert Peel, which lasted from November 1834 to April 1835. From this time till the return of Sir Robert Peel to power in September 1841, Sir Henry Hardinge remained in opposition. At the latter date he returned to Ireland to hold the office of chief secretary under Earl Grey, where he remained until 1844.

Towards the close of the year 1843 Sir Henry Hardinge came to India, but did not allow further than the day, that the directors of the East India Company thought that the time had come when it was necessary for them to recall Lord Ellenborough from the high post of governor-general of India. It was stated by Sir Robert Peel in his place in the House of Commons, that the ministers of the Home Government were at issue as to the propriety of this step, they were quite of one mind as to the selection of his successor; and that when the premier recommended Sir Henry for the vacant post, on the ground of his great experience of civil matters, his high personal character, and his military eminence, the chairman of the company answered that his own choice had already fixed upon the same individual.

In 1844 he accordingly undertook the government of India, and was sworn into office on landing at Calcutta in the July following. On his arrival he found the vast territories under British rule enjoying the most profound peace. The disasters of the Afghan campaign had been avenged; Sir Colin Campbell had triumphantly defeated the Sikhs at Meesana and Hydroabad; Scinde itself had been annexed to our dominions; and theMaharatt war had been terminated by the submission of the Durbar at Gwalior. The governor-general, rich in the experience of very many details of government, in which he was not slow to perceive that considerable reforms were needed. Able and indefatigable in his efforts, he did his best to bring about a better feeling and a more friendly footing than had hitherto existed. To the claims of the natives to many privileges; he promoted a stricter discipline among the troops in general; he lent his powerful aid to the organisation of those Indian railways which have since been carried on with himself master of the business of Sir Lord Dalhousie; and in short, he did all that was in his power to promote the welfare of the community at large.

But the course of Indian events was not long destined to flow on in peace. A storm of war and bloodshed was gathering in the north; and Sir Henry Hardinge, with all his precaution, could not have foreseen or avoided the events which awaited him. The death of Ranjeet Singh, the 'Lion of Lahore', had paved the way for an infinity of plotings and counter plotings. The line of succession of the Lion of the Lion, it seemed that the controlling power had left Lahore; the young maharajah, Dhuleep Singh, a child of four years old, was, together with his mother, in the hands of the Sikhs; the Sikh solovy, who was the ruling power, was anxious to extend his dominion, and clamoured to be led against their English neighbours. Active preparations were made by the Sikhs for crossing the Suraj; but long before the public had any idea of what was going on, Sir Henry Hardinge was on the alert, and had quietly concentrated a force of 32,000 men and 66 guns round Ferozepore, Lodianah, and Umballa. The governor-general reached the latter place about the middle of December, and, proceeding to Lodianah, inspected the various cantonments, and made himself acquainted with the military resources of the place. Sir Robert Peel, Sir Richard Wellesley, and Sir John Conolly, then a young man, and Afterwards the Duke of Wellington, Lord Hardinge trod most carefully and religiously in his Grace's steps. In 1816 he married the Lady Emily Jane Stewart, daughter of Robert, first marquis of Londonderry, and widower of the late Duke of York; and by her he had one daughter and two sons. The younger son, Arthur, now captain and lieutenant in the Coldstream Guards, was aide-de-camp to his father in the battles on the Suraj, and was also present at the Battle of Lucknow. His eldest son, Sir John Hardinge, married in 1856, and was succeeded by his eldest son, Charles Stewart, born in 1828, who had been private secretary to his father while governor-general of India.

Hare, Julius Charles, a distinguished English divine and controversialist, was born in 1796, and was one of the sons of the Rev. Robert Hare, rector of Hursmonceaux and vicar of Ninfield in Sussex, who was the son of Dr. Francis Hare, bishop of Chichester. He was educated at Trinity College, Cambridge, and graduated B.A. 1816, and M.A. 1819. In 1832 he was instituted to the rectory of Hursmonceaux (a living belonging to his family); in 1840 he was appointed Archdeacon of Lewes; in 1851 he became one of the prebends of the Dean of Chichester; and in 1853 he was nominated one of her Majesty's chaplains. He died at Hursmonceaux on the 23rd of January, 1855. Such are the principal external facts in the life of a man whose personal influence in his day was of very great, and who has left behind him a rich and considerable literature. His first literary appearance of any note was in 1837 when, in conjunction with a younger brother (the Rev. Augustus William Hare, M.A., of New College, Oxford, and rector of Alton Barnes, Wiltshire, who died in 1854), he published a series of learned articles in a series of periodical articles entitled 'Gueses at Truth, by Two Brothers.' (Subsequent and enlarged editions of this work have been pub-
lished; and ao a 'Second Series' under the same title).

In 1825, in conjunction with the Rev. C. Thirlwall, afterward Mr. Harriett became a pupil of the first two volumes of 'Niebuhr's History of Rome,' from the German. Of his subsequent publications, the following are the most important:—The Children of Light: a Sermon,' 1825; 'A Vision of Niebuhr's Almost Forgotten History of Rome,' Quarterly Review,' 1829; 'Sermons preached before the University of Cambridge,' 1839; 'The Victory of Faith, and other Sermons,' 1840; 'The Better Prospects of the Church: a Charge to the Clergy of the Archdeaconry of Bengal,' 1840; 'The Duty of the Church in Times of Trial; a Charge,' 1848; 'The True Remedy for the Evils of the Age: a Charge,' 1849; 'Education the Necessity of Mankind: a Sermon,' 1851; 'The Contest with Rome: a Charge,' 1853; 'Vindication of Luther against his Recent English assailants (H. Hallam, Esq., J. H. Newman, W. G. Ward, and Sir William Hamilton),' 1854. From this list it will be seen that Archdeacon Hare's chief activity was in theological literature and ecclesiastical controversy. In the church, he was known as one with a high tone, as being at the head of what has been called the 'broad party,' as distinct from either the 'high' or 'low.' The liberality of his opinions in philosophy and his tolerance of religious differences may be inferred from the fact of his having been chosen as a measured experience of John Sterling, whose 'Remains' he edited, with a long and affectionate Memoir, in 1848. It was Mr. Carlyle's dissatisfaction with his memoir, as an account of his friend, that led him to write his 'Life of Sterling.' Mr. Hare's memory is held in high re estimation, not only by those who regarded him as an ecclesiastical leader, but also by many who had learnt to respect him as an earnest thinker on social and philosophic subjects.

HAMILTON, John. [Chemistry, S.S.]

HARPAGUS, William. [PULMONITIS]

HARRAR. [HUMANS]

HARRINGTON. [CUMBERLAND]

HAROLD. [BEDFORDSHIRE]

HARTE. [Mineralogy, S.S.]

HARTLEY. [Northumberland]

HASELEMERE. [Surrey]

HASSELTIA, a genus of Plants belonging to the natural order Myrtaceae, was named by Link (1749), in reference to a corolla with the tube contracted in the middle; the throat naked; the limb campanulate, 5-parted and cleft. The stamens are inserted in the throat. Anthers large, cuspidate, callose at the back, adhering to the stigmas; the ovary double, succulent; the fruit a drupe, heart-shaped. Sir Hugh North, 2, distinct, and long; seeds with a stipitate coma at the lower end.

H. arbores is found in Java, near Tjampam. It is a handsome tree, with large, elegantly formed leaves; the heart acute at each end, smooth above, paler and a little downy on the under side. The flowers are large, yellow-white, in axillary fascicles. In Java the milk obtained from the trunk by incision, mixed with honey and reduced with boiling water, is employed as a powerful draught for destroying the tapeworm; it is however apt to produce inflammation of the intestines, and in some cases has proved fatal.

HATCHEIN, Thomas. [Chemistry, S.S.]

HAY, Sir WALTER. [General, Sir HENRY, K.C.B., was born April 6, 1795, at Bishopwearmouth, near Sunderland, at which latter town his father carried on an extensive business as a ship-builder and merchant. His father retired from business in 1799, and purchased Ingress Park, Darford, Kent. Young Havelock was placed in the Charterhouse School, where he distinguished himself by his application and success, and where he had for contemporaries the Greek historians Thirlwall and Grote, Archdeacon Julius Hare, Sir C. L. Eastlake, and several others who have attained eminence in life and education. In 1813 the King chose a fession selected for him, in 1813 he was entered of the Middle Temple, and in 1814 became a pupil of Chitty. His own inclination was however for a military life. His elder brother, Col. Hay, had attracted notice by his gallant conduct on more than one occasion in the Peninsular—honorable testimony is borne to his merits

In Napier's 'History of the Peninsular War'—and through him Henry applied for a commission. In July 1815 he was made Lieutenant, and in January 1816, with his regiment in England till 1823, when having exchanged into the 13th Light Infantry, he embarked for India, and from this time his career of active duty may be dated, he being appointed a second lieutenant into the 26th Bengal native cavalry.

The Birmese having made various invasions into British territory, and collected large armies with the avowed determination of driving the English out of Bengal, Lord Amherst, in March, 1824, issued a formal declaration of war against them. The King was appointed Assistant-Adjutant-General, and in that capacity took part in the chief operations of the war. When the court of Ava was constrained to sue for peace, Havelock was named one of a commission to obtain the royal signature to the treaty which was signed at Finschharn, April 11, 1826.

Lord Cordermner having formed a military depot at Chinsurah, Havelock was appointed adjutant of it in 1827. On Feb. 9th, 1829, he married Hannah the third daughter of Dr. Marshall, the learned Baptist missionary at Serampore, with whose theological opinions his was in a great measure coincided: and it is noteworthy, as an illustration of the extent to which these to Hindoo notions has been carried in India, that it was long after made a matter of serious complaint against Havelock, on the part of the priests of Serampore, the quarters for religious worship, and the charge was greatly investigated by the higher authorities. On the breaking up of the Chinsurah depot Havelock returned for a while to his regiment; afterwards proceeded to Calcutta, passed an examination in which he was pronounced as a suitable candidate for a regimental adjutant. On the breaking out of the first Afghan war in 1838, Captain Havelock (for he had in this year, after twenty-three years' service, been promoted to a company), was placed on the staff of Sir Willoughby Cotton, and accompanied the army throughout the campaign, being present at the storming of Ghuznee, the capture of Kabul, &c. He published as account of this campaign, 'A Narrative of the War in Afghanistan in 1838, 1839, 1840,' 2 vols. 8vo, Lond., 1840.

Cotton's forces was now sent to the Punjab with a detachment, and placed as Persian interpreter on the staff of Major-General Elphinstone. On the occurrence of difficulties in Afghanistan in 1841, he joined the force of General Sale, and shared in the desperate fighting through the Khoord Cabul Pass and the difficult country beyond it to Ghuznee; in the protracted and noble defence of which fortress, as well as in the final defeat of Akbar Khan in the open field, April 7, 1842, the name of Havelock was one of the most conspicuous. Havelock was received into the brevet majority and the companionship of the Bath. As Persian interpreter he accompanied General Pollock in his march, and took part in the several encounters in which the army engaged. In 1848 he was appointed Persian interpreter to the mission which Sir John Haddo and Sir H. Haddo went out with in the winter of 1847-8, when they fought in the battle of Maharajpoor in which the Mahrattas, 16,000 strong, were defeated with a loss of about 3,400 men. In 1844 he was made lieutenant-colonel by brevet. The following year was marked by the commencement of the next war. He was present at the battles of Moodkee, December 18, 1845 (where two horses were killed under him), Fereeshah, December 21, 32, and Sobraon (where he lost another horse) February 10, 1846. When peace was restored he was appointed Deputy-Adjutant-General of the Queen's troops, at Bombay. In 1849 he came to England on leave of absence for two years on account of ill-health. On his return to India, Lord Hardinge, who had witnessed his gallant and skilful in the battles near the Sutlej, made him first Queen's General, and then Adjutant-General of the Queen's troops in India.

When the Indian government declared war against Persia, Colonel Havelock was detached with the expeditionary force under General Sir Jamset Jutiee in command of the second division of the army, and took part in the brilliant affair of Bushire, and was present at the capture of Meshanmehr. The war ended, he embarked in the Erius for Calcutta with the gallant 78th. The vessel was wrecked, April 1847, but the colonel and all the officers and several hundred of their followers were spared to do memorable service in the rescue of their countrymen and countrywomen subjected to far more fearful peril than that of shipwreck, and in inflicting retribution on their saboteurs. A noble officer of the line.

Immediately on reaching Calcutta he was detached with the rank of Brigadier-General to Allahabad. He left that
city on the 7th of July at the head of a column of about 1900 Europeans and Sikhs to retake Cawnpore, where the garrison had been treacherously massacred after surrendering on terms, and where some of the women and children were still in the enemy's hands. He had to force his way against terrible odds, but he made good his ground, and on the 16th of July he arrived at Cawnpore, after a march of about 500 miles, with only about 5,000 mutinous sepoys—his own force being 1000 Europeans and about 300 Sikhs. On the 17th he entered Cawnpore, too late notwithstanding all that he and his noble army, which was quite blind-footed, had done in the last eight days marched 196 miles, and won four actions against overwhelming odds. Hardly waiting to give rest to his men, or to pay the last rites of sepulture to the mangled corpses of those who had been forcibly murdered in Cawnpore and in the vicinity of the town, he began, on the 19th of July he again inflicted a severe defeat on the mutineers, and finding that Nana Sahib had evacuated his stronghold of Bithoor, renewed his march. But he had to fight at every step, stout fortresses had to be captured, and at length after, on the 16th of August, achieving his ninth victory over six times his own numbers, he found his men so reduced by death, wounds, and sickness, as to render it imperative on him, after almost coming within sight of the beard that commenced his advance on Cawnpore—not however without being able to communicate cheering words to the besieged. Being strengthened by the arrival of General Neill with a small additional force, and joined by his old comrade, General Sir James Outram, Havelock at the head of his forces proceeded on his way, but with the genius of a true-hearted soldier, he in an order of the day announced to the army that "in gratitude for and admiration of the brilliant deeds in arms achieved by General Havelock and his gallant troops," he was about to leave his post to return to England, and call upon the government to release his brother from the cell that had imprisoned him. He then proceeded to London, and Hayden's enthusiasm showed itself without a bound. For a time he did scarce anything but draw, write, and talk about them; and to the last he was glad to believe that to his earnest pleas with men in power the purchase of them for the nation was partly due.

Haydon exhibited his first picture at the Royal Academy in 1807. The title alone will show the daring of the young painter, "Joseph and Mary resting with our Saviour after a day's journey on the road to Egypt." Mr. Hope, author of "Antiquities," became the purchaser of this picture. The reputation which the artist gained by it gave him increased energy and ambition. 'Detustus' was the subject chosen by him next year; and from this period Haydon dates the commencement of his "career." He was accused of liberality or mismanagement in hanging his 'Detustus' where it could not be seen, and of a want of historical painting as the cause of their refusal to admit him as an associate, while they admitted less skilful artists. The next work he exhibited was "Christ and the Woman of Samaria," and the following year was exhibited in the British Institution, where it received the praises of the public, and the prize of the committee. About this time the Elgin Marbles were first exhibited in London, and Hayden's enthusiasm about them was boundless. For a time he did scarce anything but draw, write, and talk about them; and to the last he was glad to believe that to his earnest pleas with men in power the purchase of them for the nation was partly due.

Haydon was refused further application to painting by his fondness for controversy; and the attacks he published on the Royal Academy, by estranging him from some personal friends among artists and the patrons of art, greatly exasperated his temper, and there can be little doubt introduced a lasting ill effect on his fortunes. From this time his life was a great extent one of strife, and of constant struggle with pecuniary difficulties. Still he was at no time without friends. Sir G. Beaumont gave him a commission for a subject from Maccabell, and his 'Judgment of Solomon' was bought by Mr. Elford and Mr. Tingcomb for 700 guineas; his 'Alexander returning in triumph, after vanquishing Bucephalus,' found a purchaser at 500 guineas in the Earl of Eggromont; and his 'Veas and Aeschias' was purchased by Lord Maltgrave. Application for admission to the Academy resulted again in disappointment.

His next great work was 'Christ's Entry into Jerusalem,' begun in 1819, and exhibited, and formed part of an exhibition of his own in Bond Street. The picture did not sell, but this did not prevent him from painting 'Christ in the Garden,' and 'ChristRejected.' In May 1821 he married. His 'Raising of Lazarus' was painted in 1823. About 1815 he had two pupils, his first being the Landseers—Edwin, Charles, and Thomas—and his purpose being "to form a school, and to establish a better and more regular system of instruction than even the Academy offered." With many drawbacks he made a good teacher, and some of his pupils at least obtained success. He had at one time a large school, but in the end he had none, and was only left with a sort of small miserable school. His last work was connected with the Academy. He painted several pictures for the Royal Academy, and was a member of it, and became an inmate of the King's Bench prison. Here he founded a subject for a successful picture in the 'Mock Election,' which took place within those walls in July 1837. George IV. purchased this work. Haydon exhibited under the subject in his 'Chariot of the Members,' which was sold for 300 guineas to Mr. Francis of Exeter. He had previously regained his liberty with the assistance.
of friends. Another picture of the same period was his 'Pharaoh dismissing Moses after the Passover,' for which he offered 1,000 guineas from Mr. Hunter, an East India merchant.

Haydon's next subjects, after making an unsuccessful attempt to obtain employment as a portrait painter, were 'The Great banquet at Guildhall' at the passing of the Reform Act, 'The Duke of Wellington at Waterloo,' which he had succeeded in getting for 40 guineas. He returned, however, after a time he was able to effect a settlement with his creditors. He now engaged with great zeal in lecturing on painting at various literary institutions in London and the provinces, and his lectures were everywhere attended with success.

The determination of the government to decorate the interior of the new houses of parliament with pictures opened a new and grand field before the imagination of Haydon. He had petitioned, written, and lectured in favour of so adornning our public buildings, and impressed with a very high notion of his own capacity for executing such works, his sanguine temperament never permitted him for a moment to doubt that he would be one of the painters selected and engaged in the business. In the vehicle in favour with the authorities, he set himself eagerly to the preparation of a cartoon. The judges gave in their decision for four copies of his, and then the question of the successful competitors, even of the third class. It was a death blow to all his hopes; and though he struggled bravely against the disappointment, he never really recovered the shock. His last work was done at the time of the first landing of the Prince of Wales in the Gulf of Botany; for the Marquis of Hertford, the Prince of Wales, who was afterwards appointed to the commissariat charge of a brigantine. After having been taken out of the hands of James Vesuvius, who had the commission for the whole, he was sent to Lake Huron to superintend the commissariat department of a naval establishment intended to be formed on the Canadian lakes. Peace however was soon afterwards made with America, and in ten months he was again in England. In 1833 he was appointed professor of art in the Royal Academy in Halifax, in 1834, and there five years on the peace establishment. After his return to England he described his experiences and adventures in America in his 'Forest Scenes and Incidents in the Wides of North America, being a Diary of a Winter's Tour from Halifax to the Canadas, and a Four Months Residence in the Woods on the Borders of Lakes Huron and Simcoe, by George Head, Esq.,' 12mo, London, 1839. In 1831 he received the honour of knighthood. Encouraged by the publication of 'A Home Tour through the Manufacturing Districts in England in the Summer of 1836, by Sir George Head,' 12mo, 1836, which was followed by another volume, 'A Home Tour through various parts of the United Kingdom,' 12mo, 1839, he published 'A Home Tour through the Manufacturing Districts: also Memoirs of an Assistant-Commissioner General, by Sir George Head,' 12mo, 1837. The first Tour includes most of the largest manufacturing towns in the north of England; 'Isle of Man, part of Scotland, the Channel Islands, and part of Ireland. They contain a large amount of information carefully collected and clearly stated concerning the places visited and the manufactures carried on in them. Both Tours were written in a spirit of curiosity; the first volume was published 'Rome, a Tour of Many Days.' He was also the author of several articles in the 'Quarterly Review,' and translated from the Italian the 'Historical Memoirs of Cardinal Racc', 12mo, 1850, and from the Latin, 'The Metamorphoses of Apollinus,' 4vo, 1851. He died in London, May 2, 1855, unmarried.

HEALTH, PUBLIC. [PUBLIC HEALTH, S.2.]

Haydon's 'Lectures' are almost his only contributions to literature. Considerable difference of opinion exists as to his merits as a painter. The exaggeration and hardness, with his language, are not always suitably commensurate with his style and principles, ascribed to his early intimacy with and imitation of Fuseli, but unjustly; they are Haydon's own, the result partly of insufficient study, partly of incomplete artistic education, more of his own physical temperament, and habit of working. But he had many merits, and he did much to raise the character of English art, and to extend an interest in and a love of it. For a fair and far from partial review of the character of Haydon as a man and an artist, the reader is referred to the concluding pages of the third volume of Taylor's 'Life of Benjamin Robert Haydon,' 2nd ed., 3 vols., 1853.

HAYESINE. [MINERALOGY, S. 1.]

HEAD, SIR GEORGE, Knight, was born in 1725, at the Hermitage, a few miles north from Rochester, in Kent. James Roper Head, father of Sir George Head and Sir Francis Bond Head, was descended from Fernando Mendes, a Jew, who came from Portugal to England, and was physician to King Charles II. The father of James Roper Head, married a daughter of the Rev. Sir Francis Head, Bart., and assumed the name of his wife's father.

George Head spent his early years at his father's residence, the Hermitage, and was afterwards educated at the Charter House School, London. Early in 1806 he obtained a commission in the British Navy, but having obtained leave of absence, in the spring of 1809 went to Portugal, where he accepted the humble situation of a commissariat clerk, and joined the British army under Lord Wellington. He was afterwards appointed to the commissariat charge of a brigantine. After having been taken out of the hands of James Vesuvius, who had the commission for the whole, he was sent to Lake Huron to superintend the commissariat department of a naval establishment intended to be formed on the Canadian lakes. HAYESINE. [MINERALOGY, S. 1.]

HEAD, SIR GEORGE, Knight, was born in 1725, at the Hermitage, a few miles north from Rochester, in Kent. James Roper Head, father of Sir George Head and Sir Francis Bond Head, was descended from Fernando Mendes, a Jew, who came from Portugal to England, and was physician to King Charles II. The father of James Roper Head, married a daughter of the Rev. Sir Francis Head, Bart., and assumed the name of his wife's father.

George Head spent his early years at his father's residence, the Hermitage, and was afterwards educated at the Charter House School, London. Early in 1806 he obtained a commission in the British Navy, but having obtained leave of absence, in the spring of 1809 went to Portugal, where he accepted the humble situation of a commissariat clerk, and joined the British army under Lord Wellington. He was afterwards appointed to the commissariat charge of a brigantine. After having been taken out of the hands of James Vesuvius, who had the commission for the whole, he was sent to Lake Huron to superintend the commissariat department of a naval establishment intended to be formed on the Canadian lakes. Peace however was soon afterwards made with America, and in ten months he was again in England. In 1833 he was appointed professor of art in the Royal Academy in Halifax, in 1834, and there five years on the peace establishment. After his return to England he described his experiences and adventures in America in his 'Forest Scenes and Incidents in the Wides of North America, being a Diary of a Winter's Tour from Halifax to the Canadas, and a Four Months Residence in the Woods on the Borders of Lakes Huron and Simcoe, by George Head, Esq.,' 12mo, London, 1839. In 1831 he received the honour of knighthood. Encouraged by the publication of 'A Home Tour through the Manufacturing Districts in England in the Summer of 1836, by Sir George Head,' 12mo, 1836, which was followed by another volume, 'A Home Tour through various parts of the United Kingdom,' 12mo, 1839, he published 'A Home Tour through the Manufacturing Districts: also Memoirs of an Assistant-Commissioner General, by Sir George Head,' 12mo, 1837. The first Tour includes most of the large manufacturing towns in the north of England; 'Isle of Man, part of Scotland, the Channel Islands, and part of Ireland. They contain a large amount of information carefully collected and clearly stated concerning the places visited and the manufactures carried on in them. Both Tours were written in a spirit of curiosity; the first volume was published 'Rome, a Tour of Many Days.' He was also the author of several articles in the 'Quarterly Review,' and translated from the Italian the 'Historical Memoirs of Cardinal Racc', 12mo, 1850, and from the Latin, 'The Metamorphoses of Apollinus,' 4vo, 1851. He died in London, May 2, 1855, unmarried.
to the embryo by the venous trunk. In the bloodvessels which are first observed in the body of the embryo, as well as in the vascular area, no difference is at first perceived between the characters of the arteries and those of the veins, and these are only to be distinguished by the direction of the blood through them. The heart, therefore, from the first, is a hollow mass of tissue which is effectuated by a constriction round the middle of the tube; and the dilatation of the posterior portion becomes an auricular sac, and that of the anterior a ventricular cavity. Between the 50th and 60th hours the circulation of the blood in the vascular area becomes more vigorous, and the action of the ventricle is no longer continuous with that of the auricle, but seems to succeed it at a separate period. At the same time the thickness of the heart becomes more and more bent together until it is doubled to the extent of much shorter relatively to the dimensions of the body, and is more confined to the portion of the trunk to which it is subsequently restricted. The convex side of the curve which is effectuated by the auricle is carried on to the ventricle in the region of the apex or point of the heart, and between the 60th and 70th hours this is seen to project forward from the breast of the embryo, much in the situation it subsequently occupies. About the same time the texture of the auricle differs considerably from that of the ventricle, the region of the heart, which is thinnest and membranous walls which it at first possessed whole the ventricle has become stronger and thicker, both its internal and external surfaces being marked by the interlacement of muscular fibres, as in the higher Mammalia. About the 60th hour the grade of development of the heart may be regarded as corresponding with that of fish, the auricle and ventricle being quite distinct, but their cavities are as yet quite single. The heart of the dog at the 21st day bears a great resemblance to the heart of the horse, which consists of a membranous tube twisted on itself, and partially divided into two principal cavities, besides the bulb or dilatation which at this period is found at the commencement of the sorts, and which corresponds with the bulbus arteriosus of fishes.

Having thus traced the evolution of the heart up to the stage which it presents in fishes, we may now inquire what is the condition of the other parts of the vascular system. At the end of the 4th day the primitive arterial trunk is seen to be divided into two canals, which separate from one another to inclose the pharynx, and then unite again to form the aortic trunk, which passes down the spine. During the first half hour of the 21st day the second arch is inclosed in a tube which incloses the pharynx in the same manner; and towards the end of the third day two other pairs of vascular arches are formed, so that the pharynx is now encompassed by four pairs of vessels, which unite again to supply the general circulation. These evidently correspond with the branchial arteries of fishes, although no respiratory apparatus is connected with them; and in fact the distribution of the vascular system of the bird on the fourth and fifth days exactly resembles that presented by many cartilaginous fishes, as well as by the tadpoles of the *Batrachia*. The first pair of arches is obliterated about the end of the fourth day, but a pair of vessels which is sent from it to the head and neighbouring parts, and which afterwards remains as the pectoral end of the heart, ventral arch has been shown to be corresponding with the inclosing vessel from the second arch. While the first pair is being obliterated a fifth is formed behind the fourth which had previously existed, and proceeds in the same manner as the fourth from the ascending to the descending sorts. On the fourth day the second arch also becomes less, and on the fifth day is wholly obliterated, whilst the third and fourth become stronger. From the third arch, now the most anterior of those remaining, the arteries are given off which supply the upper extremities and the vas-eis of the head are now brought into connection with it by means of the communicating branches, which previously joined the third with the second arch. When these vessels are fully developed, the branchies by which these arches formerly sent their branches to the head and general circulation are extinguished about the thirteenth or fourteenth day the whole of the blood sent through the two anterior arches is carried to the head and upper extremities, instead of being transmitted to the descending sorts as before. The arches which remain the branchial arches, that is to say, the development of which into the sorts and pulmonary arteries will be described in connection with the changes which are at the same time going on in the heart. During the fourth day the cavities of the heart become defined, and the left auricle and ventricle, the latter of which is indicated externally by the appearance of a dark line on the upper part of its wall, and this after a few hours is perceived to be correspondingly divided into two chambers, the left auricle and ventricle, divides it into two nearly spherical sacs. Of these the left is at first much the larger, and receives the great

2 Q 2
systemic veins; the left has then the aspect of a mere appendage to the right, but it subsequently receives the veins from the middle and lower lobes, and at last acquires an increased size. The septum between the auricles is by no means completed at once: a large aperture (which subsequently becomes the foramen ovale) exists for some time at its lower part, so that the ventricle continues to communicate with the sinus venosus. The valve, which is often closed by the prolongation of a valvarul fold, which meets it in the opposite direction; it remains pervious however until the animal begins to respire by the lungs, and sometimes is not completely obliterated even then. The division of the ventricles begins a little time before that of the auricle, and is effected by a sort of duplicature of its wall, forming a fissure on its exterior and a projection on its interior; and thus a septum is gradually developed within the cavity, which grows firm and rises higher up, until it reaches the entrance to the bulb of the aorta, where some communication exists for a day or two longer. At last however the division is complete, and the inter-ventricular septum becomes continuous with the inter-aauricular, so that the heart may be regarded as completely a double organ. The progressive stages presented in the development of this septum are evidently analogous to its permanent conditions in the various species of reptiles; but it must not be lost sight of that the division of the inter-aauricular septum is first developed, and that it is in the embryo at any instance in which the inter-ventricular septum is absent or imperfect.

The changes which occur in the heart of the *Mammalia* are of a precisely similar character, and as they take place more and more completely as the heart grows in the organism. After the septum of the ventricles begins to be formed in the interior a corresponding notch appears on the exterior, which as it gradually deepens renders the apex of the heart double. This notch between the right and left ventricles continues to become deeper until about the eighth week in the human embryo, when the two ventricles are quite separated from one another except at their bases; this fact is very interesting from its relation with the similar permanent form of the *Dipnoi* and the Ichthyosaurus, in which the inter-ventricular septum is still imperfect, so that the ventricular cavities communicate with each other, as in the chick on the fourth day. After the eighth week however the septum is complete, so that the cavities are entirely insulated; whilst at the same time their external walls become more and more directed towards the external surface, and the notch between them is diminished; and at the end of the third month the ventricles are very little separated from one another, though the place where the notch previously existed is still strongly marked.

In the adult animal the distribution of the arterial trunks to their final modifications, by which the creature is enabled to become an air-breathing animal. The first, second, and third branchial arches are replaced by the brachial and coronal arteries, which join the common trunk with the primitive arterial trunk except at its commencement, when the third pair of arches arises with the other trunks from its dilated bulb. This remains a single vessel even after the ventricles have been separated. About the fifth or sixth day the bulb in the chick becomes flattened, and its opposite sides adhere together, so as to form two tubes running side by side; one of which unites with the left, the other with the right ventricle. The one on the left becomes the ascending aorta, that on the right the pulmonary artery. A knowledge of the changes which go on in the development of the heart enables us to explain some of the malformations to which it is subject.

(Carpenter, *Principles of Physiology, General and Comparative*.)

HEATHER. [Enica.] HEIMIA, a genus of Plants belonging to the natural order *Lythraceae*. It has a hemispherical campapulate calyx, bracteolate at the base, with six erect lobes and as many alternate broad sepals, with both the angles; this is alternate, with six erect lobes; stamens 12, somewhat equal; ovary sessile, nearly globose, 4-celled; capsule included within the calyx; seeds numerous, minute, and wingless. Glabrous herbaceous plant, slender, shorter than the calyx.

*H. salicifolius* is found in New South Wales, and in the vicinity of Jorullo. It has ternate or opposite leaves, the upper often alternate, on very short stalks, lanceolate, acute, narrowed to the base. The petals are obovate. It is a powerful mollis. and diuretic. The Mexicans consider it a valuable medicine, and call it Hanchinol.

HEINE, HEINRICH, was born on the 1st of January, 1800, at Düsseldorf, in the Prussian Rhine-Provence, of Jewish parentage. His father was deeply interested in education, and at an early age acquired an increased size. As he was intended for the mercantile profession, he was sent in 1816 to Hamburg, to receive the necessary instruction and training. He remained there till 1819, when his father, as well as his other relatives, was enabled by his attainments to wish for him a literary career, and he published his first collection of poems, "Gedichte, von Heinrich Heine," 12mo. Some of the earliest of these productions date as far back as 1816, and several of them had previously appeared in the periodical called *Der Sprecher* and *Jahreskalender* of 1817. He afterwards made tours to the highest points of the Alps, and after his return to Berlin published his remarks in the *Gesselschafter*. In 1823 he published his tragedy of "Almanson," together with a one-act tragedy named "William Radcliiff," and a "Lyrisches Intermezzo." While he remained at Berlin he also published in *Der Sprecher* a series of letters under the head of "Briefe aus Berlin," which attracted much attention. In 1823 he returned to Göttingen, and resumed his studies in jurisprudence. On the 30th of July, 1826, he took a degree in law. Having no disposition of establishing himself there as an advocate, the practice of the law however seems to have been as little suited to the character of his mind, now developing itself, as the pursuits of trade. He appears about 1826 to have visited Paris, and was in the vicinity of that of the New Testament, in the Lutheran form, but afterwards became an unbeliever. While at Göttingen, in 1828, he had made a tour in the Harz Mountains, of which he published an account at Hamburg, *Die Harzreise*, 1829. His after-days were devoted to literature. He continued to reside during the summer of his life. In this year he published his series of letters "On Nobility" ("Über den Adel"), Hamburg, 1831. In 1833 appeared his essays "On the Origin of the Classical Mythology," and many others. He retired to Elbing, and became a member of the Schilesische Literature, 12mo, Paris and Leipzig, and in 1836, his remarks on the state of France, "Franzosische Zeitbände," 12mo, Hamburg, which is a collection of articles previously published in the *Augusberg Gazette*. The "Salon," one of the most important of his prose works, was published at Hamburg, in 4 vols. 8vo, 1834-40. About this period he married a Frenchwoman, who was a Roman Catholic, and married her according to the Roman Catholic ritual. His observations on the "Romantic School" ("Die Romantische Schule") appeared in 1836 at Hamburg. In 1840 he published his bitter personal attack on Börne, with whom he had become acquainted when he went to Paris in 1831, "Über Ludwig Börne," 8vo, Hamburg. In 1844, he removed to Germany for the last time. After his return to Paris he published his "Deutschland, ein Wintermärchen" ("Winter's Tale"), which is a description of his journey. In 1847 he experienced an attack of paralysis, which deprived him of the sight of one eye. In 1848 he removed to Heidelberg, in bad health, but continued to reside at the same place till 1848, when he removed to Lon-
HERAT. [Persia.] HERBARIUM, the name given to specimens of Plants when they have been collected and dried. The possession of an herbarium is almost essential to the study of systematic Botany, as it is impossible to cultivate at once the larger proportion of the species of plants which inhabit the earth's surface. The use also of an herbarium will be found constantly to supply the place of recent plants. Hence all persons interested in study botany possess themselves of an herbarium more or less extensive and of the nature of their studies. The following hints for forming an herbarium are chiefly derived from Professor Balfour's valuable 'Class-Book of Botany.'

The specimens are dried and kept in the herbarium should, if possible, be gathered in fine weather, and free from external moisture. In selecting them care should be taken to have the plants in a perfect state of growth, with all the parts from which the characters of the order, genus, or species, are taken. The entire plant, where practicable, should be preserved. Of course this is impossible with trees, but the completer the specimens the better for study. In trees, portions of the branches, with the leaves, flowers, or fruit, should be taken, where possible, sections or small portions of the stem, roots, &c. In the case of tall and slender grasses and sedges, they may be folded once or twice backwards and forwards, to make room for them on a single sheet. Thick branches, roots, stems, &c., may be split to allow the paper to get into them. The_pulvinus from both the staminiferous and pistilliferous flowers should be obtained. Some plants, as species of the genus Rubus and Salix, demand that both flowering and leading shoots should be gathered. In gluing the plants on to the paper, care must be taken to avoid splitting the plants, and paper may be obtained. A sheet of varying thicknesses should be employed, and pressure may be applied by means of a weight or tramp. The latter is the most easy process whilst travelling. In order that the plants may be dry free from moisture, either by surface or internal distillation, a hibernal paper strapped between two pieces of board, into which the plants needing drying may be thrust at once.

The paper employed may be ordinary blotting-paper, but the paper-makers have made a paper for botanical use which may be more advantageously employed. In London, Dentall's drying-paper is used; there is also another paper used in Scotland, called the Edinburgh botanical drying-paper. It is made in sheets 18 inches long and 11 inches broad. This paper is of a strong and compact texture, and according to the size of the drying-paper. Several sets of boards of varying thicknesses should be employed, and pressure may be applied by means of a weight or tramp. The latter is the most easy process whilst travelling. In order that the plants may be dry free from moisture, either by surface or internal distillation, a hibernal paper strapped between two pieces of board, into which the plants needing drying may be thrust at once.

In putting down the plants the following plan should be pursued:—"A parcel of not less than four sheets of paper is put on one of the outside boards, then one or more specimens are laid on this sheet according to their size. The specimens should be spread out carefully, their natural habit being preserved as far as possible. When plants require to be folded, the slips of paper are so arranged that the intermediate portions as to retain them in their position. Having placed one specimen or set of specimens on the sheet, another parcel of not less than four sheets is laid over them; and in doing this the leaves and other parts are arranged with the hand or the forceps. The same is repeated until the whole is out, the paper may be increased or diminished according to circumstances. Very succulent and wet plants require frequent changing and much drying. Most specimens will dry in eight or ten days. Succulent plants need to be killed.
first by immersion in boiling water. Aquatic plants and wet plants should be placed in a napkin and pressed before they are put into the paper. The moist paper will dry in ten or twelve hours. Along with the plant a label should be inserted, with all particulars known about the specimen, as where gathered, what elevation, &c.

When the specimens are thoroughly dry a selection is made for the herbarium. These should be fastened by means of the margin of the wide paper, 17 inches long and 10 inches broad. The name of the plant, its locality, or any other particulars, may be then written on the paper. In order to preserve the specimens from the attacks of insects, &c., they should be touched with a strong solution of corrosive sublimate, or any careful spirit, or the like. The sheets may then be arranged in a case, according to their genera or natural orders.

Rita, specimens of wood and bark, large roots, lichens and algae on rocks and stones, may be arranged in drawers, glazed cases, or glass jars. Succulent fruits and roots are best preserved in a strong solution of salt and water, or in pyrogallic acid, diluted with 5-6 parts of water, or in alcohol. In some instances a solution of 4 ounces of bay salt, 5 ounces of burnt alum, and 5 grains of corrosive sublimate, in 2 quarts of boiling water, has been used with advantage. These jars are best covered with a stout piece of cloth and to which is attached a label.

HERMASIA, a genus of Plants belonging to the natural order Parcenioideae. It has 5 sepals; 5 stamens inserted with the 5 stamens on a perigynous ring; 2 stigmas nearly sessile; fruit 1-seeded, indehiscent, membranaceous; leaves alternate, petiolate, entire, ovate-lanceolate, which are described in the next catalogue. Three have been recorded as natives of Great Britain. One, *H. hirsuta*, is a doubtful native; the other two are very rare.

*H. glabra* has a prostrate herbaceous stem, with clusters of sessile flowers collaicing on the lateral branches into a slightly leafy spike. It has been found in Suffolk and Lincolnshire in England, and in West Kerry, Ireland.

*H. ciliata* The sepals are tipped with a large bristle; the flowers are distinct, staminate and androecial. It has been found at Lisard Point, Cornwall.

HERMINIUM, a genus of Plants belonging to the natural order Orchidaeae and the tribe Ophrysineae. The perianth is bell-shaped, segments all erect; lip 3 lobed, tumid beneath at the base, without a spur; glands of the stalks of the pollen-masses exserted, naked. *H. monorchis*, the Musk-orchis, is a British species. The stem is about six inches high, and the spike of flowers is dense and slender; the sepals and petals are very small.

HERNE BAY. [Kest.]

HERNSHAW, or HERONSHAW, a name for the Common Heron. [Heron.]

HERONS BILL. [Erodium, S.I.]

HERSCHL, CAROLINE LUCREZIA, the sister of the great astronomer Sir William Herschel, was born at Hanover on the 16th of March, 1770. Till her twenty-second year she lived with her parents in her native place; after which she came over to England to reside with her brother, then established as an organist at Bath. When Sir William exchanged his profession as a musician for those astronomical labours which were to immortalise his name, his sister became his constant and most valuable assistant—first of all in the first commencement of his astronomic pursuits," says an authority who writes from intimate knowledge, "her attendance on both his daily labours and nightly watchings was put in requisition, and was found so useful that, on his removal to Datchet and subsequently to Slough, she performed the whole of the arduous and important duties of his astronomical assistant—not only reading the clocks and noting down all the observations from diaries, as an amanuensis, but subsequent to the publication of the nebulae, she performed the numerical calculations necessary to render them available for the purposes of science, as well as a multitude of others relative to the various objects of theoretical and experimental inquiry in which, during his long and active career, he was at work. For the first part of the year 1779 she received in receipt of a moderate salary allowed her by George III. But, in addition to these labours performed expressly as her brother's assistant and amanuensis, she found time to perform others of a similar character on her own account. Though sitting up frequently all night till day-break, more especially in winter, while her brother required her help, she was able, by snatchling such intervals of time as her brother's occasional absences permitted, to conduct a series of observations of comets, &c., with a small Newtonian telescope which he had constructed for her. Her special employment with this instrument was to sweep the heavens for comets; and so successful was she in this employment that she discovered seven comets, of at least five of which she was entitled to the rewards of the Royal Society for the year 1779. The date of the discoveries of the seven comets were as follows:—August 1, 1776; December 8, 1778; January 9, 1790; December 15, 1791; October 7, 1793; November 7, 1795; August 6, 1797. Besides the discovery of these comets, she had the merit of having discovered one of several remarkable nebulae and clusters of stars, included in her brother's catalogue.

In 1798 she published, with an introduction by her brother, an astronomical work of great value, entitled 'Catalogue of Stars taken from Mr. Flamsteed's Observations, contained in the second volume of the Historia Coelestis, and not inserted in the British Catalogue, with an Index to point out every observation in that volume belonging to the stars of the British Catalogue: to which is added a collection of Errata that should be noticed in the same volume.' In this work, which was published at the expense of the Royal Society, no fewer than 561 stars observed by Flamsteed, but which had escaped the notice of the framers of the 'British Catalogue,' were discovered during the whole of her brother's career Miss Hershel remained by his side, aiding him and modestly sharing the reflection of his fame. After his death, in 1822, she returned to her native Hanover to spend the remainder of her days. They were unusually prosperous in their time, owing to the value of the shares for two years of age which she left England, she lived for twenty-six years longer. Even these venerable years were not spent idly. In 1838 she completed a catalogue of the nebulae and clusters of stars observed by her brother, for which labour the Astronomical Society of London voted her a gold medal. She was also chosen an honorary member of that Society—an honour very unusual in such a case. Living in dignity and tranquility, retaining her memory and the full use of her faculties almost to the end, she survived her death from anxiety and fatigue the highest respect from the king and crown-prince of Hanover and from other German sovereigns, she survived till the 9th of January, 1848, when she died in her ninety-eighth year.

Among the female examples of the pursuit of knowledge, very few names deserve so high a place as that of Caroline Herschel.

HILL, ROWLAND, VISCOUNT, was born on the 11th of August, 1772, at the village of Frees in Shropshire, where his father, John Hill, Esq., resided till the death of his brother, Sir Richard Hill, Bart., when he succeeded to the title, and removed to the family mansion and estate at Hawkstone in Shropshire. Sir John Hill had sixteen sons and daughters, of whom Rowland Hill was the fourth child, and was a nephew of the Rev. Rowland Hill, the celebrated preacher. He was educated in his native county, where he remained till 1790, when he entered the army as an ensign in the 38th regiment of foot. Having obtained leave of absence, he went to a military academy at Strasburg, where he remained till January 24, 1791, when he was appointed lieutenant in an independent company under Captain Broughton. On the 16th of March, in the same year, he was appointed lieutenant in the Shropshire regiment of fencibles. He went to the Netherlands to pursue his military studies at Strasburg, but returned to England at the end of the summer, joined his regiment at Edinburgh January 18, 1792, and remained in Scotland till the end of the year. In the following year 1793 he raised as an independent company, for which service he received his commission as captain on the 23rd of March. He took his company to Ireland, delivered the men over to the 38th regiment, and returned to Shropshire in June. Lord Hood takes him to Dublin on the 17th of August 1798, Captain Hill, before
H I N

H I S

He was attached to any particular corps, was employed to
serve as aide-camp to three successive generals, Lord M'Grave,
General O'Hara, and Sir David Dundas. On the 13th of
December, 1793, Lord Hood and Sir David Dundas appointed
him the bearer of dispatches to England, where he arrived
at the 14th of January, 1794. In the early part of that year
Mr. Graham (at that time Sir Thomas Graham Graham, subse-
sequently Lord Lynedoch) having raised a regiment of infantry,
offered Captain Hill the rank of major in it, on the condition
of his supplying a certain quota of men, which he did. This
regiment with the other, January 1, 1794, he was destined to
wear as his uniform. It was afterwards augmented to 1000
men, and he was promoted to the rank of lieutenant-colonel.
On the 1st of January, 1800, he was advanced to the rank
of colonel.

Mr. Hill went through arduous duties with his regiment
at Gibraltar and elsewhere, till, on the 8th of March 1801,
he landed with his regiment at Alexandria in Egypt, as part of
the army under Sir Ralph Abercromby. He received a
wound on the temple in the action of March 15, 1801.

After the defeat of the French he returned to England,
where he arrived on the 1st of April 1802. He performed
military duty in England and Ireland till 1806, when he
accompanied the expedition to the river Waas in Ger-
many, with which he was appointed a deputy to the 1st
coast, which the insect becomes a real inactive police, with
the limbs of the perfect insect laid along the breast, as in other species
which undergo the strict coruscate species of transformation.

Mr. Beddome was the first to discover these curious particulars
and attributes of the insect from these singular eggs, that he carried them
in his pocket by day and took them to bed with him at night, in
order that they might have a uniform degree of warmth ;
and was his surprise therefore when, instead of grubs as he
expected, perfect insects were produced.

These insects are interesting in their habits. They live
exclusively upon quadrupeds and birds; the horse is espe-
cially subject to the attacks of one of these species, hence
the term Hippobosces. This species is the type of the
genus Hippobosces, in which the eyes are large and distant,
being placed at the sides of the head; the antennae are in
the shape of tubercles with three dorsal setae: the wings are
large. Mr. Curtis observes that these flies move swiftly, and
like a crank, sideways or backwards; they are very tenacious
of life, and live principally on horses, attaching themselves
to the belly between the hind thighs and under the tail,
where they are less protected by hair. It is remarked by
Latreille that the sex foams them, and horses suffer
very little from them.

In the New Forest, the Horse-fly is the most astonishing
degree. Mr. Samouelle says, "From the flanks of one horse I have obtained six handfuls, which con-
sisted of upwards of a hundred specimens. They abound
most on white horses and ponies."

The other genera are: Ornithomyia, Craterina, Oxy-
pterum, Hemorota, Melophaga, Feronia, Lipotaspis,
and probably Brusa. Of these the first three are British,
and are found upon various birds, the Craterina birudula
depositing its eggs like a cocoon in the nest of the swallow,
where it receives all the necessary warmth; for which it
repays the poor swallow by sucking its blood. The wings in
this genus are very long and narrow. The genus Melophaga
embraces a single species, Melophaga cariosa, which is destitute of
wings, and attacks the sheep. It is of a dark reddish colour,
with the abdomen whitish. It is commonly called the
Sheep-Louse, and is so tenacious of life that Ray states
that it will exist in a fleece twelve months after it is born,
and can menstruate, and lays a tinge to the wool, which is very
difficult to be disengaged.

Hippoglossus. [Phlebotominae.] Hippuricus Acid. [Chemosian, S. 2.] Hiricus. [Oed.] HISTOLOGY (teve and Orke), that department of science
which embraces the facts relating to the ultimate structure of
the parts of plants and animals. These facts have
been comprehended under the term General Anatomy,
more recently they have been classified under the term Histology. It is only recently that this word could be
needed, for the observations upon which the science
has been founded have only been made since the extensive employ-
ment of the microscope. It may be said to have originated
with Marcello Malpighi (1628-1723) and Grew (1641-
1692), and Wren (1628-1723) at the time when magnifying glasses
were first constructed of such a kind as to be useful in observing
the structure of plants and animals. The ultimate composition of organised bodies was unknown to ancient observers, as well as those who lived in the middle ages. It is true that Aristotle and Galen speak of homogeneous and heterogeneous parts of the body; and Fabrius, at the beginning of the 17th century, went even further by thinking that all the tissues were made up of minute structures which were the same throughout the body. The idea that what are now called the tissues of the body, yet the more minute structure of these parts was entirely hidden from these observers. Even after the time of Malpighi and Leuwenhoek, we do not find them dealing with a minute structure of the tissues till the beginning of the present century. We can only point to such men as Fontana, Muy, Lieberkühn, Hewan, and Prochaska, as having engaged in isolated observations upon the structure of various tissues. One of the earliest attempts at a systematic arrangement of the tissues of plants was made by Slack, in the 39th volume of the Transactions of the Society of Arts, in a paper on the Elementary Tissues of Plants, in Vegetation, published in Müller's Archiv für Anatomie und Physiologie, Part ii. 1838. He here pointed out, that in the formation of vegetable cells, small sharply-defined granules are first generated in a granulose substance, and around them the cell-nuclei (cytoplasm) are found, which appear like granulose coagulations around the granules.

The results of these observations were communicated in 1837 to Schwann, who, struck with the resemblance between the cells of animals and those of plants, conceived the idea that the same history of development would be found true of the parts of animals that had been discovered by Schleiden in the parts of plants. From this time the science of Histology was rapidly developed, and we cannot more appropriately present it in the condition in which it has been by the labours of Professor Kölliker, in his introduction to his Manual of Histonology:—

"In the year 1835, in fact the demonstration by Dr. Th. Schwann, that the perfectly identical cellular component of all animal organisms, and of the origin of their higher structures from these elements, afforded the appropriate conception which united all previous observations, and afforded a clue for further investigations. If Bichat founded Histology more theoretically by constructing a system and carrying it out logically, Schwann has by his investigations afforded a basis of facts, and has thus won the second laurels in this field. What has been done in this field, and what Schwann has been doing, with regard to physiology and medicine, and in fact of great value in a purely scientific point of view, inasmuch as a great deal which Schwann only indicated or shortly adverted to, the general of the cell, the import of the nucleus, the development of the higher tissues, their chemical relations, &c., has received a further development, but all this has not amounted to a step so greatly in advance as to constitute a new epoch. If, without pretensions to preeminence, it be permitted to speak of future, this condition of Histology will last as long as no essential modification of the rod towards penetrating more deeply into organic structure, and becoming acquainted with those elements of which that which we at present hold to be simple is composed. If it be possible that the facts, such constitute the cell, can be discovered, and the laws of their apposition and of the alterations which they undergo in the course of the origin, the growth and the activity of the present so-called elementary parts, should be made out, then a new era will commence for Histology, and the discoverer of the law of cell-genesis, or of a molecular theory, will be as much or more celebrated than the originator of the doctrine of the composition of all animal tissues out of these elementary parts.

"In characterizing the present position of Histology and of its objects, we must by no means forget that, properly speaking, it considers only one of the aspects which the elementary parts present to observation, namely, their form. If, in the answer must be made of the connection between what is the understanding of the microscopic forms, and with the laws of their structure and development, not with any general doctrine of the elementary parts.

"Composition and function are only involved as far as they are to be found in the origin of forms and to their variety.

"Whatever else respecting the activity of the perfect elements and their chemical relations is to be found in Histology, is there either on practical grounds, in order to give some useful application of the morphological conditions, or to complete it, as from its intimate alliance with the subject, it is added only because physiology proper does not afford a due place for the functions of the elementary parts.

"If Histology is to attain the rank of a science, its first need is to have as broad and certain an objective basis as possible. To this end the minuter structural characters of animal organisms are to be examined on all sides, and not only in fully-formed structures, but in all the earlier periods from their first development.

"The process by which the elements have been perfectly made out, the next object is to discover the laws according to which they arise, wherein one must not fail to have regard also to their relations of composition and function. In dis-
HIT 305 HON
velop from these their higher elementary parts, stands firm; though it must not be understood as if cells, or their deriva-
tives, were the sole possible or existing elements of animals. In the same way, Schwann’s conception of the genesis of cells, though applicable to organs and parts of their molecular forces, after the manner of Donders, Dubois, Ludwig, and others, combined with a more profound microscopic exami-
nation of them, such as has already taken place with regard to the muscles and nerves, and further, a histological treat-
ment of embryology, such as has been attempted by Retkerti, Vogt, and myself, will assuredly raise the veil, and bring us step by step nearer to the desired though perhaps never-to-
be-reached end.”

We refer here to some of the more important works and papers to be consulted on this subject.

Kölleri, Manual of Human Histology; Sharpey, General Anatomy, in Quain’s Elements of Anatomy; Beale, The Microscope and Its Application to Clinical Medicine; Todd and others, on Anatomy; Gerber, Elements of the General and Minute Anatomy of Man and the Mammalia; Goodall, Anatomical and Pathological Observations; Hassell, Microscopic Anatomy; Bowman, On the Structure of Voluntary Muscles (Phil. Trans., 1840); Kienan, On the Surface of the Brain and Spinal Cord; Manual d’Anatomie Générale; Mohl, On the Vegetable Cell; Owen, Lectures on Comparative Anatomy; Quækett, Lectures on Histology; Schleiden, Principles of Scientific Botany; Schleiden and Sachs, Comparative Botanical Researches (Sydney, 1874); Cyclopedia of Anatomy and Physiology; Robin, Histoire Naturelle des Végétaux Parasiitaires; Carpenter, Principles of Physiology, General and Comparative. BIBLIOGRAPHY. [HOBSON.] HOLLIBRIDGE, [P. B.]
HOLIBUT, or HALIBUT. [P. F.]
HOLLYHOCK. [A. T.]
HOLMAN, JAMES, known as The Blind Traveller, was born in or about the year 1787. He entered the royal navy in December 1798, and was appointed lieutenant in April 1807. At the age of twenty-live an illness which resulted from his professional duties deprived him entirely of his sight. On the 29th of September 1812, he was ap-
pointed Commodore of the Mediterranean Squadron, and there are six, with a governor. By degrees, when he had become accustomed to his condition, in 1819, partly the state of his health and partly a desire for change induced him to set out on a journey to the Continent, of which he published an account in the British Magazine. He was taken in the Years 1819, 1820, 1821, through France, Italy, Savoy, Switzerland, parts of Germany bordering on the Rhine, Holland, and the Netherlands; comprising Incidents that occurred to the Author, who has long suffered under a total Deprivation of Sight; by James Holman, R.N. and K.W., Svo. 1822. On the 19th of July 1822, he embarked on a voyage to St. Petersnburg, whence he proceeded to Mos-
cow, Novgorod, and finally to Irkutsk, the capital of Eastern Siberia. After four months, he reached Tientsin, and began sufficiently firm, to have crossed over, and travelled through Mongolia and China. At Irkutsk however an order was received by the Russian authorities from the Emperor Alexander, prohibiting him from proceeding any further, and he was compelled to return. He was commissioned by a Russian officer to the frontiers of Germany, and was treated with external politeness combined with much harshness and severity. After his return to England he published ‘Travels through Russia in the Years 1825, 1826, and 1827, at the Expenses of the Royal Society of London;’ also, during the years 1823, 1824, and 1825, while suffering from total Blindness, and comprising an Account of the Author being conducted a State Prisoner from the Eastern Parts of Siberia, 2 vols. Svo, 1825. But though Travels were intended, as he states, to have been the commencement of a series of travels and voyages round the world, which it afterwards accomplished, and which occupied about five years. After his return he published 1 A Voyage round the World, including Travels in Africa, Asia, Australasia, America, &c., from 1827 to 1832; 4 vols. 8vo, 1834. In this ‘Voyage’ he visited the islands of Madeira, Teneriffe, and the western coast of Africa; thence he crossed the Atlantic to the west coast of South America, and turning north, calling some time in Brazil, he recrossed the Atlantic to the Cape of Good Hope, and visited Caffraria, Madagascar, Mauritius, and Ceylon, whence he passed to Hindustan. He next passed by the Straits of Malacca to New South Wales, Van Diemen’s Island, and returned over the south side of Cape Horn to England. In 1843 he visited Dalmatia, Montenegro, Bosnia, and Servia, and passed in 1844 by Moldavia into Transylvania. Lieutenant Holman’s series of voyages and travels is no less remarkable for the much interest when they were published, chiefly from the extraordinary circuit of the world having been accomplished by a man who was totally blind, but they are, as might be expected, of little value for any information which they contain. He died July 30, 1857.

HOLCANTHUS. [CLEISTOGON.]
HOLSWORTHY. [DEVONSHIRE.]
HONDURAS, Republic of, of Central America, occupies the elevated country between the table-land of Guatemala and the plains of Mosquitos and Nicaragua. It lies between 14° 5’ and 16° 30’ N. lat., and about 86° and 92° W. long. of Cape Horn; but a narrow tract extends southward between Salvador and Nicaragua as far as the Gulf of Conchagua on the Pacific, 13° 30’ N. lat. Honduras is bounded E. by the Mosquito district, S. by the province of Cortes, W. by the republics of Nicaragua and Salvador, and N. by the state of Veracruz. The surface is about 30,000 square miles; the population is about 250,000, of which about 150,000 are Indians. The capital is Trujillo, the river of the same name, which is merely a stream rising in a bay formed by Cape Honduras; and Omoa, a small but good harbour near the western extremity of the republic. The whole of this coast is extremely unhealthy, and consequently very thinly peopled. The small tract owned by Honduras bordering on the Gulf of Conchagua, in the Pacific Ocean, is also low, subject to be inundated by spring tides, and very unhealthy; but in neither case does the insalubrious influence extend far inland.

The surface of the country is greatly broken. It may be described as a table-land traversed by several ranges of hills running from north-west to south-east with secondary ridges branching obliquely from them. The general level of the table-land is perhaps about 4000 feet; the highest point is on the southern slope of the Sierra de Tamaulipas, near the shores of the Caribbean Sea a ridge of mountains, the Sierra Omoa, extends from Cape Honduras to Caballo Point, near which is Mount Omoa, 7000 feet high, which gives its name to the ridge. The culminating point of this ridge is the peak of Congroy, 875 W. long., which is 7000 feet above the level of the sea. The ridges which traverse the interior of Honduras do not attain any great altitude above the general level. Between the ridges are long, wide, open and fertile valleys, which are intersected by few rivers, the longest of which is the east. Near the western end of the state are the broad valleys of the Chamalicon and the Uina, which are overgrown by thick forests of mahogany, cedar, and fustic trees. Along the southern side of the territory there is a river which divides the waters which flow into the Pacific from those which fall into the Atlantic; but only a few peaks attain any con-
siderable elevation. From this ridge, and from the transverse ridges north-west of it, a series of high and steep hills rise perpendicular from a broad depression, and form the table-land of Honduras with that of Guatemala. The valleys between these ridges are of comparatively moderate width. The principal rivers flow into the Caribbean Sea. Beginning on the west coast of the Chipas, which rises on the Merendon Mountains near 14° N. lat., and flows generally northern direction into the Bay of Honduras a little east of Pinta de Caballos. For a large part of its upper course it flows through a wild and uninhabited country; but as it approaches the sea the valley opens out to a great

2 R
width, its slopes being covered with vast forests of valuable timber trees. Like most of the rivers of the state, the navigation of the Chamalicon is impeded by a bar at its mouth. The navigation of the Ulus is much smaller and more important. It is formed by the union near Santiago of several branches, the longest of which rises not far from the borders of Salvador; it falls into the sea a short distance west of Punta de Sal after a course of about 300 miles, enough for navigation in the long, straight coast line. The next river of any size is the Truxillo, the mouth of which forms the harbour of the same name. East of this is the Aguan, which after a course of about 100 miles discharges itself by two branches into the Caribbean Sea, about 30 miles each, and is the last of the long, straight coast line of the province. Towards the south-eastward, and along the north coast, are several narrow valleys, the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use.

Climate, Soil, Productions.—The climate, except along the coast, is on the whole salubrious, though the temperature is somewhat high. Goitre is common in the elevated districts. The valleys opening to the sea are very fertile, but moist and unhealthy. Those from which the air of the sea is impeded by the hills are less so, and their soil is more habitable, but their fertility is not so great. On the tableland, and in the districts not contiguous to the Caribbean Sea, the dry season begins about the close of October, and lasts until the end of May; during which time only a few showers are received, there being a few rainless days during the month of June. Thunder is frequent, and is followed by long and heavy rains. But even during this time it rains only in the evening and night: from six o'clock in the morning till four or five o'clock in the afternoon, no clouds pass over the sky, and there is dry and pleasant. Towards the middle of October the north winds set in with frequent thunderstorms, and after them the dry season begins.

The most important natural productions are the vast forests of mahogany, cypress, pimento, and numerous other valuable trees; but owing to the badness of the roads, the scarcity of labour, and other local causes, they are turned to comparatively little account. From the same causes, and from the indisposition of the inhabitants to steady labour in the fields, agriculture is in a very backward state; not only are immense tracts of fertile land wholly neglected, but the land which is under cultivation is very far from being rendered as productive as it easily might be. Maize, rice, sorghum, cotton, tobacco, plantains, bananas, and various fruits and vegetables are the principal articles grown, but scarcely in sufficient quantities for the requirements of the inhabitants.

In the western districts of Gracias, tobacco of very fine quality is raised, but not enough for exportation. The chief market of the province is Comayagua, which occupies nearly the N., and contains the capital of the republic: Gracias to the south-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal: Tegucigalpa is on the north-west of the province. All of the provinces are very hilly, and are divided by several narrow valleys, the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use.

HONDURAS IS DIVIDED INTO SEVEN DEPARTMENTS—Comayagua is the most important. It contains the capital of the republic, Gracias to the south-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal: Tegucigalpa is on the north-west of the province. All of the provinces are very hilly, and are divided by several narrow valleys, the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use.

The climate is in a very backward state; not only are immense tracts of fertile land wholly neglected, but the land which is under cultivation is very far from being rendered as productive as it easily might be. Maize, rice, sorghum, cotton, tobacco, plantains, bananas, and various fruits and vegetables are the principal articles grown, but scarcely in sufficient quantities for the requirements of the inhabitants.

In the western districts of Gracias, tobacco of very fine quality is raised, but not enough for exportation. The chief market of the province is Comayagua, which occupies nearly the N., and contains the capital of the republic: Gracias to the south-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal: Tegucigalpa is on the north-west of the province. All of the provinces are very hilly, and are divided by several narrow valleys, the only river of the state which does not enter the Caribbean Sea. The roads throughout the republic are mere tracks worn by continual use. Some yielding emeralds. Jasper, asbestos, and cinabir are likewise obtained. Excellent marble is wrought.

Divisions, Towns, &c.—Honduras is divided into seven departments—Comayagua is the most important. It contains the capital of the republic: Gracias to the south-west, and Santa Barbara to the north-west of Comayagua, both of which extend to Guatemala, and Santa Barbara includes the coast as far east as Punta de Sal: Tegucigalpa is on the north-west of the province. thermometer seldom rises above 83° Fahr. even in the hottest time, and during the wet season it sinks to 60°. In June, July, August, and September heavy and frequent rains fall, until the country, a woody region, is almost entirely being engendered by the marshy miasma arising from the swamps. The soil by the coasts and rivers is a rich alluvial deposit, and very fertile. On the higher ground the country is divided into patches of the most luxuriant growth, and the logwood-tree abounds in the swamps. Ceder and other valuable timber-trees are among the natural products.

The plantain is extensively cultivated. Maise, ne, cassava, arrow-root, yams, &c. are grown. Cotton, sugarcane, tamarind, and tobacco are cultivated, and on the coast, the woods the red tiger, the black tiger, the tiger-cat, the leopard, and other wild animals, and game, are found. Turto abounds on the keys.

Hornby is governed by a Superintendent, and a Public Meeting, consisting of seven magistrates appointed by the inhabitants. The superintendent is immediately subordinate to the Governor of Jamaica, from whom he holds a commission. He is assisted in the administration of government by an Executive Council, consisting of the chief justices, the attorney-general, the officer commanding the land forces, and the public treasurer. An Act of the local legislature has however been passed by which the constitution of the council and assembly is proposed to be altogether remodelled. However, the Williamsmoor prison, in the parish of Morant Bay, which has been called New Gaol, to which afterwards he made alterations costing 40,000L. on its conversion for the cellular system. In London he was the architect of Roger's Club-House in St. James's-street, the Naval and General Life Insurance Offices in Chandler's Wharf, and the Atlas Fire Office in Cheapside. His general manner for such buildings was derived from the class of edifices to which the Banqueting House, Whitehall, belongs. His last work, St. Mary's Hospital, Paddington, which is inferior in character, and perhaps understood by him greatly, was opened in 1839. To this latter he added alterations totalling 30,000L. and another for a column of Victory to be erected in India with 12 columns in successive tiers, from the base upwards, of the shaft.

Although not possessing those high qualifications in art and science which the architect now strives to bring to his profession, Hopper's life is not the less an important one in the later history of architecture. He lived to enter the eighty-first or eighty-second year of his age, dying on the 11th of August 1856 at his cottage, which had been built by him, at Bayswater in life. In his possession a frame which could support almost any amount of fatigue,—and although he was contemporary with the less esteem of the Englishman, he never drank anything but water. He practised athletic exercises with Jackson the boxer, and was active in command of a company of the volunteers. His features and form have been exactly given by Mr. J. Tennouth, the sculptor in the relief on the eastern compartment of the Church of St. Peter's Column, to the sailor who is supporting a wounded boy. He was always connected with the leading personal characters of his day, and this circumstance afforded him inestimable service. He was the friend of a number of eminent men of business and the house of knighted, but this he declined, as well as offers from Alexander I., emperor of Russia, and the Duchess of Oldenburg, for him to settle at St. Petersburg. The obituary notice in the 'Builder' (vol. xiv., p. 481)—the facts of which are not clearly apparent, like those above, derived from family sources—calls him 'a man of mark and power,' a conclusion...
English history, poetry and mythology, have all or nearly all the same character, for which perhaps there is no word so descriptive as that of 'academick.' His figures are almost always well drawn; of elegant proportions; have the established 'classic' contour and expression, or absence of emotion; are clothed or partly clothed, in a more conventional 'drapery' which nymphs and goddesses, whatever their position, wear so easily and gracefully in pictures and statues, despite the ordinary laws of gravity, which however may fairly be regarded as not applying to such beings; and, as they are shown to us in the 'Sun' ('1760), to afford a pleasing flow of lines and an agreeable conformity to the rules of pictorial composition; while the colouring, if not rich and glowing, is chaste and harmonious. They were in fact good 'academick' pictures, and they are no more. Always strictly attentive to the forms and proper members in whatever can be a 'Venus rising from the Sea,' a 'Love animating the Statue of Pygmalion,' or a cold 'Primavera Hope,' can that by any chance give the slightest shock to the nerves of the most susceptibility—who is not shocked by any undraped female beauty. But if his "beauties of fair forms" are never like those of Etti trebling on the verge of the voluptuous, they never like them are buoyant with the exuberance of life and youthful vigour—never exhibit the firm and wide and pleasing flow of lines and action. They are works to be looked at with a certain quiet admiration of the artist's skill, not to seize the attention and linger in the memory. In a word, they are works of taste, not of genius.

Mr. Seymour was elected an associate of the Royal Academy in 1801; in 1808 he became an academican; and in 1811 he was appointed secretary to the Academy, an office he held till his death, though for several years previously its active duties were performed by an assistant. He died on the 9th of October 1847.

The titles of a few of his pictures will sufficiently indicate the range and character of his subjects. Of his sculptural paintings, the most ambitious are 'Christ blessing Little Children'—perhaps as an altarpiece in the chapel in Little Berkshire Street; 'the Angel appearing to St. Peter in Prison'; and 'Aaron staying the Plague.' The great bulk of his pictures as already mentioned are however those in which the subjects were chosen with a view to afford him the opportunity of painting the nude female form; and to this class his best pictures belong. The most admired of these is his 'Birth of Venus,' painted in 1829. Others are 'The Marriage of Cupid and Psyche,' 'Proserpine,' and large stock subjects; but a large number consists of figures floating in the air with such titles as the 'Pleasures,' the 'Solar System,' the 'Circling Hours,' 'Morning,' 'Night,' &c. Besides numerous pictures from Singer, his favourite poet, Milton, Shakspere (especially the Midsummer Night's Dream') &c., he is said to have gone through the works of the etchers on the Grand Tour. He is said to have collaborated with a great many artists that on the occasion of the first cartoon competition in 1843, he did not shrink from entering the lists, though then seventy-three years of age, and in the nude encounter with the young artists fresh from the schools, his cartoon, 'Man bested by contending Passion,' carried off one of the premiums of 100l.

In 1814 Mr. Howard won the prize for a medal for the Patriotic Society, and thenceforward he was generally employed in preparing the designs for the medals and great national events. He also received the especial commendation of the president, Sir Joshua Reynolds, for the excellence of his historical design. In the following year he visited Italy, and at Rome he and Flaxman pursued their studies in conjunction.

On his return to England Mr. Howard was employed to make drawings for the Dilettante Society, and designs for bookplates; he also painted some portraits. His first contribution to the Royal Academy, 'Beasts and Ancestors' and the 'Planes of the Sun' were much admired by persons of classical taste; and from this time for more than half a century Mr. Howard continued, without a single intermission, to send to each annual exhibition some painted or etched designs of the classes of which these may be taken as the types. In fact the number of pictures which he executed, though illustrating themes from the Scriptures, and from Greek, Roman, Italian, and the
It has opposite, stalked, broad, cordate, or oval leaves, not at once at the base, pointed, membranous, smooth, from 2 to 3 inches long; petals from 1 to 3 inches long; umbels lateral or axillary, simple, many-flowered.

Flowers numerous, green, with pedicles as long as the peduncle. Corolla flat; crown of appendages turbinate, truncate. The public house house of a standing ship, which is divided, horizontal, obtuse, about 3 or 4 inches long, and 4 inches in circumference. The root and tender stalks produce nauseas, and promote expectoration. The leaves peeled and dried in a basket are used by the natives of India as a diuretic in the early stages of jaundice. As to the manufacture of gunpowder, they are employed in the same way to promote suppuration.

Several species of this genus are cultivated in our gardens on account of their elegant flowers, which, from their curious wasp-shaped emblems, have been named by the Botanical emblems of the pea family. They are a genus of Leguminosae. HUME, JOSEPH, was born at Montrose in the year 1777. His father was the master of a small coasting- vessel, and after his death his widow supported herself by keeping a shop in Montrose. Having received the most rudiments of education, including Latin and a smattering of Arabic, at a school in his native town, he was apprenticed in his fourteenth year to a surgeon. In 1793 he entered the University of Edinburgh for the purpose of prosecuting his medical studies; and having obtained his seat in 1799, he proceeded to the University of Surravas, where he was appointed surgeon to the East India Company in 1797. He distinguished himself not only in his medical capacity, but also by acting as purser on his voyage out, and conducting a most complicated business in a very successful manner. He was afterwards made a regular interpreter, and in addition to his duties as a surgeon, he became Persian interpreter, commissary-general, and paymaster and postmaster of the forces in the prize agencies.

It is said that he owed the first step of his progress to this superiority in chemical knowledge. He learned a method of detecting the presence of damp in the government stores of gunpowder on the eve of Lord Lake's Mahatta war. Nothing is more surprising than the amount of hard work performed by him, which is fully attested by his letters to his family. He was so well acquainted with Place, Mill, and other disciples of the school of Jeremy Bentham; and devoted considerable time and energy to the foundations of savings banks and of schools on the Lancasterian system. He was also a candidate—though an unsuccessful one—for a seat at the Board of East India Directors. In 1818 he re-entered parliament as member for the Montrose burgh, for which he continued to sit without interruption until 1830, when he was chosen by the constituency of Midlothian. He represented that county during the whole of the period of agitation which preceded the passing of the Reform Act and down to 1837, when he was defeated, but he was returned through the influence of Mr. O'Connell for Kilkenny. In 1841 he contested Leeds without success; but in 1848 he went to the contest, and was elected for the Montrose burgh, which he represented down to his death, a period of thirteen years.

For many years Mr. Hume stood nearly alone in the House of Commons as the advocate of Financial Reform: indeed in the public expenditure, no man ever did so much practical good as Joseph Hume, through a long career of perseverance and industry. Disregarding the fashion of the age and the opinions of the world, he distinctly extended the public expenditure of the country and right. In most of the political and social movements of the last quarter of a century he was an important actor: the working man eat bread which he helped to cheapen, waits through parks which he helped to procure for him, and in a sea of plenty the month is a month. The authority of his decisions on his exertions. He more than once refused to accept office under Liberal governments, and he devoted a part of his own wealth to the social and political objects which he had in view. His speeches devoted to the interest of farmers occupy in bulk several volumes of "Hansard's Debates." He incessantly advocated reforms in our army, navy, and ordnance departments, of the Established Church and Ecclesiastical courts, and of the general system of taxation and the early days of the war, he brought to efficient service a military flying, nautical improvement, and imprisonment for debt. With little active assistance, he carried the repeal of the old combination laws, the laws prohibiting the export of machinery, and the act for preventing mechanics from going abroad. His opposition to the use of colonial and municipal abuses, election expenses, the licensing system, the duties on paper and printing, and on articles of household consumption. He took an active part in carrying Roman Catholic emancipation through both the House of Commons and the Lords, and in the passing of the Reform Act of 1832. A remarkable passage in his life was his discovery, in 1835, of an extensive Orange plot, commencing before the accession of William IV. An account of this transaction, in all the minutest of detail, will be found in Miss Harriet Marri- nnan's "History of the Thirty Years Peace."

The health of Mr. Hume began to break soon after the parliamentary session of 1864, and he died at Burnley Hall, near Huddersfield, on the 20th of May, 1865. At the time of his death he was a magistrate for Norfolk, West-minster, and Middlesex, and a deputy lieutenant for the latter county. As a proof of the esteem in which he was held, we may add, that in the House of Commons he was the only speaker of the House of Commons who spoke of "the character. He married a daughter of the late Mr. Burnley, by whom he left a family of several sons and daughters. His eldest son is Mr. Joseph Burnley Hume, barrister-at-law. HUMPHREYS, ACID. [CHEMISTRY, S. 1.]

HUSBAND. [DICTIONARY, S. 2; SEPARATION, JUDICIAL, S. 2; WIFE, S. 2.]

HYACINTH. ST. [CANADA, S. 2.]

HYAENACHE, a genus of Plants belonging to the natural order Thalia. Hyaenachne, is a genus of Polyphyletic Animals, including the Fesh-Water Hydra, or Polyple. It has the following technical definition.—Polyplecrops locomotive, single, naked, gelatinous, subcylindrical, but very contractile and mutable in form; the mouth encircled with a single series of granulated filiform tentacles. As of all the forms of Polyphyletic animals the Hydro is the most interesting, we give an abstract of their history, from Dr. Johnston's "British Zoophytes":

Leeuwenshoek discovered the Hydra in 1703, and the uncommon way its young are produced; and an anonymous Aborigines of South America were discovered in England about the same time; but it excited no particular notice until Trembley made known its wonderful properties about the year 1744. These were so contrary to estab- lished experience, and so foreign to every preconceived notion of animal life, that by many they were regarded as impossible fancies. Leading men of our learned society were daily experimen- ting on the creature and transporting it by careful posts from one to another, while even ambrosialsm were for- getting to the respective order of early intelligence in the engraving theme. The Hydro are found in fresh waters only. They prefer slowly-running or almost still water, and adhere to the leaves and stalks of submerged plants. The body is exceedingly contractile, and hence liable to many changes of size. Some of them can contract into a minute top or button, and when extended it becomes a nar- row cylinder, being ten or twelve times longer at one period than another, the tentacels changing in size and form with the body. On the point opposite the base, and in the centre of the tentacles, there is a little opening or aperture, which leads into a wider cavity, excavated as it was in the middle of its body, and from which a narrow canal is continued down to the sucker. When contracted, and also when about to change in size, a kind of "middle degree of extension" the sides seem to be minutely crenulated, an effect possibly of a wrinkling of the skin. The tentacels encircle the mouth and radiate in a star-like fashion; but they seem to originate a little under the lip, for in a very short time the mouth is surrounded by a circle of tentacles, which are cylindrical, linear, or very slightly tapered, hollow, and roughened, at short and regular intervals, with whorls of

tubercles, which under the microscope form a very beautiful and interesting object.

The central part forms a slender membranous tube, filled with an albuminous nearly fluid substance, intermixed with some oelaginous particles; and at certain definite places this substance swells out into tubercles or denser wart-like nodules, which are arranged in a spiral line. Every nodule is furnished with a hollow tube or spind as organ of touch, and with a very singularly constructed organ for catching the prey. The organ of touch consists of a fine sac, inclosing another with thicker paries, and within this there is a long ciliated hair. From the two prongs of the cilia above there projects a long cilium, or capillary spine, which is non-retractile and apparently immovable. Surrounded by these cilia, and in the centre of the nodule, is placed the captor organ, called the 'basta'; this consists of a long outflattened sac-like nodule, imbedded in a small aperture even with the surface. At the bottom of the sac, and within it there is a sucker-like vesicle, on whose upper depressed surface is seated a solid ovate corpuscle, that gives origin to and terminates in a calcareous sharp arrow, or arrow, that can be pushed out at pleasure, or withdrawn, till its point is brought within the sac. When the Hydra wishes to seize an animal, the sagittes are protruded, by which means the surface of the tentacula is roughened, and the prey more easily caught, as the sagittae being in the same time injected—a conjecture offered to explain the remarkable fact of the almost instant death of the prey. The nodules of the tentacula are connected together by means of four white threads, which unite, forming, moreover, shell-less spaces by their intersections. These are the extensor muscles of the tentacularum. They are again joined together by transverse fibres, which Corder believes to be adductor muscles, and to have also the power of shortening the tentacularum. But whether these are the muscles of the apparatus of itself sufficient to effect the wonderful extensibility of these organs—from a line, or, as in H. fusca, to upwards of eight inches—and to produce this degree of elongation, it seems necesary to have superposed the propulsive agency of a fluid. Water fibres, such as may by swelling into the stomach through the oral aperture, whence it is forced by the vis-a-tergo, or drawn by capillary attraction, into the canals of the tentacula, and its current outwards is sufficient to push before it the soft yielding material of which they are composed, until at last the resistance of the living parts suffices to arrest the tiny flood, or the tube has become too fine in its bore for the admission of water attenuated to its smallest possible stream;—it is inconceivably slender may indeed be imagined, but there is no room for it strong enough to equal it, seeing that the tentacula of H. fusca, in the transparent, can be compared to nothing groser than the visible filaments of the goosebird's web.

The tentacula, usually found attached, can nevertheless move from place to place, which it does either by gliding with imperceptible slowness on the base, or by stretching out the body and tentacular to the utmost, fixing the latter, and the contracting the body towards the point of fixation, loosening at the same time its hold with the base; and by reversing these actions it can retrograde. Its ordinary position seems to be pendent, or nearly horizontal, hanging from some floating leaf or weed, or stretching from its sides. In a glass of water the creature will crawl up the sides of the vessel to the surface and hang from it, sometimes with the base and sometimes with the tentacula downwards; and again it will lay itself horizontally. Its locomotion is very slow, and the disposition of the scopheus is evidently sedentary; but the contortions and nutations of the body are a little vivacious, while in seizing and mastering its prey it is surprisingly nimble, seizing a worm with as much eagerness as a cat catches a mouse. It enjoys light, and expands more freely under its influence; hence we generally find the Hydra near the surface and in shallow water. The Hydra are very voracious, feeding only on living animals. In composition, however, Trembley found they might be fed on minced fish, shell-fish, and mutton. They will sustain long fasts with no other food. Small worms, crustacea, and insects seem to form a favourite food. Sometimes two polyae will seize upon the same worm, and most amusing is it then to watch the exertion and struggle of the two, sometimes seeing the weaker polyae growing the weaker polyae by the stronger, which however is soon disregarded with me other less than his dinner. This is more curious when contrasted with the fate of the worms on which they feed. No sooner are they seized than they evince every symptom of painful suffering, but their contortions, instead of being relaxed, more tenderly follows their capture. How this effect is produced is still a matter of conjecture. Worms are in ordinary circumstances most tenacious of life, and hence one is inclined to think that, at least in the Hydra, the worm is lost in the Hydra's grasp. To the Entomatostrachus the touch is not equally fatal, their shells evidently protecting them from the poisonous secretion. The Hydra is chiefly celebrated on account of its manner of propagation. It is like scopheuses and cladii, but is distinguished by the power of continuing and multiplying its race, principally however by the process of subdivision. During the summer season a large tubercle arises on the surface, which lengthening and enlarging every hour, in a day or two develops in the middle a small aperture, through which the tubercle, and becomes in all respects except in size similar to its parent. It remains attached for some time, and grows and feeds, and contracts and expands after the fashion of its parent, until it is at length thrown off by a process of exfoliation, or sloughing. They develop with great rapidity in warm weather, and sometimes the young ones themselves breed others, and they again a third or fourth generation before they become separated from the original parent. Two or three are known to arise from the same parent, and forty-five young ones in two months. In autumn the Hydrae generate by internal oviforin gastræalæ, which issue from the body, and lie during the winter in a quiescent state, and issue at the first warmth of the spring. Few observations have been made on these ova, so that their structure, source, manner of escape, and condition, are scarcely known.

These are the moles in which the Hydrae naturally multiply, and can be increased by artificial sections of the body in the same manner that a perennial plant can by shoots or slips. If the body be halved in any direction each half in a short time grows to a perfect Hydra; if it be divided into four or eight or even minuted into forty, each portion will grow, and develop into a perfect Hydra, which is itself capable of being multiplied in the same extraordinary manner. If the section is made lengthwise so as to divide the body into two or more slips connected merely by the tail, they are speedily reunited into a perfect whole, or if the pieces are kept saunder each will become a perfect poly. If the tentacula are cut away, new ones are quickly produced, and the lost-off parts are not long without a new body. When a piece is cut off the body the wound speedily heals, and as if by instinct new tentacula are produced, by which polypae sprout from the wound more abundantly; when a poly is introduced by the tail into another body, the two unite and form one individual, and when a head is lost, if the polyae are not lost, new polypae issue from the new head, which may chance to want one. And the creature suffers nothing itself by all these apparently cruel operations; for before the lapse of many minutes the upper half of a cross section will expand its tentacula and catch prey as usual, and the portions of a longitudinal division will after an hour or two take food and retain it. A polyt poyl cut transversely in three parts requires four or five days in summer and longer in cold weather for the middle pieces to produce a head and a tail, and the tail part to get a body and head, which they do in pretty much the same time. And what is still more extraordinary, polypae produced in this manner grow much larger and are far more prolific in the way of their natural increase than those which were never cut. When such pieces were cut off the body and immediately put together, the walls of the polypae were so thin that the new polypae were not clad round a very small and slender worm, but seemed to pech it fast till they could master and devour it, which they did
with as much greediness as any. It was first observed in England in the spring of 1743 by Mr. Ducane of Essex. It appears to be a hardy animal, and is easily kept for a long period of time in the water.

_H. vulgaris_ is of an orange-brown or yellowish colour, body cylindrical, tentacles 7 to 12, as long or longer than the body. It is found in muddy ponds and slowly-running waters of small size, which it resembles in its habits and form. It is always of an orange-brown or red colour, the intensity of the tint depending on the nature of the food, or the state of the creature's nutrition. Every part of the body is generative of young, which are frequently seen being born from the parent at the same time in different stages of their growth.

_H. attenuata_ is of a light oil-green colour, the body attenuated below, with pale tentacles longer than itself. It is found in ponds, and in Yetholm Loch, Roxburghe. This is a larger animal than _H. vulgaris_, and comparatively less sensitive to external impressions, and of a more graceful form. Its colour is a pale olive-green, with paler tentacles, which are considerably longer than the body, and hang like silken threads in the water, waving to and fro without assuming that regular circular disposition which they commonly do in _H. viridis_. Dr. Johnston says he has not observed more than one young at a time, which pulsatiled from near the middle of the body, and after this has attained a certain growth the polyp has the appearance of being dichotomously divided.

_H. oligactis_ (Polypes a Long Bres de Trembley) is brown or rufescus; inferior half of the body suddenly attenuated; tentacles are more than twice the length of the body. It is found in still waters in England, rare. In a pond at Hackney, and in a pond at Cranmore, near Bath, September 1812. The tails of these are long, slender, and transparent, and when placed under the microscope a long straight canal may be seen passing from the body or stomach to an opening at the end thereof; these are rather lighter coloured than _H. vulgaris_, and have seldom more than 6 or 8 arms, but those capable of great extension. It may be worth while to call attention to the remarkable resemblance of the Hydra fusca to the Osellina cirrosa of Müller, which is an intestinal worm.

(Johnson, History of British Zoophytes; Landborough, Popular History of British Zoophytes; Trembley, Memoires pour servir a l'Histoire d'un Genre de Polypes d'Eaux douces, the Hague, 1743; Baker, Natural History of the Polype.)

HYDRIDE. A family of Snakes belonging to the Cucumis sub-order of Dr. J. E. Gray's arrangement, and the Cucumis. This does not exist, which includes the Hydroiza and Boida. [Boa.] It is thus characterised—Belly covered with narrow elongate shields or scales, nearly resembling those of the back.

The following is a synopsis of the genera, and a list of the species, compiled from the Catalogue of the specimens of Snakes in the British Museum:—

**Hydrida.**—The ventral shields narrow, hexagonal or band-like; the hinder limbs not developed; the eyes and nares superior, vertical, the latter valvar, generally placed in the middle of a shield, with a slit or groove to its outer edge;fangs moderate, intermixed with the maxillary teeth; pupil small, round; tail compressed or conical. They live in the sea or salt-water lakes, or in fresh water.

Synopsia of the Genera.

1. Tail compressed (except in _Aerchordus_). Belly keeled, with two rows of small scale-like shields, often united together in a single, rather broad, 6-sided shield.

4. Head shielded to the nape. Nasal shields very large, with their hiperculated, superior, nasoral nostril on the outer edge; the frontal shields two pairs, small; loreal shield none; labial shields large, high. _Hydrina._

These are the true Sea-Snakes. They coil themselves up on the shore, and appear to live on sea-weed, and lay their eggs on the shore. They are often found aseep on the rocks where they are easily caught, for they cannot descend into the sea without throwing themselves on to their backs. This arises apparently from the necessity of expelling the air from their large lungs. They are often thrown ashore in the surf, and are occasionally caught by waders who live in fresh water. Their bite is venomous, and they are held in great dread by fishermen wherever they occur, on this account. In spite of their venomous properties, one species at least, the _Hydrias (Peleamis) bicolor_ is said by Cuvier to be eaten at Tahiti.

a. Scales square or 6-sided, placed side by side.

* Head elongate, depressed.

1. _Peleamis._

_P. bicolor._ Pacific Ocean. For figure see _Hydrias_.

_P. ornata_. Borneo.

** Head moderate, rather compressed; gape moderate.

2. _Lopemis_.—Head moderate, short, rounded in front; dorsal scales square; ventral shield broad, 6-sided.

_L. curvata_. Malay.

_L. Handschuri_. Borneo.

3. _Austrias._—Head moderate, short, rounded in front; dorsal scales 6-sided; ventral shield 6-sided.

_A. ornata_. Indian Seas.

_A. Belcheri_. New Guinea.

4. _Microphysophala_.—Head small; scales 6-sided; ventral scales keeled.

_M. gracilis_, the Kadal Nagam. Madras.

5. Scales ovate, 6-sided, imbricate, keeled, or with the keel reduced to a tubercle on the centre of the scales; head and gape moderate.

* Labial shields occupying the greater part of the lip; the eyes over the fourth, or rarely over the third, or the fourth or fifth shield; ventral shield united.

5. _Euhydrias._—Rostral plates narrow, erect; lower linear, sunken, nasal narrowed in front; ventral shield flat; head moderate, short; eyes moderate.

_E. Bengalensis_. Madras.

_E. Volakadyen_. Madras.

6. _Hydrophis._—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shield flat; head short; eyes small.

_H. Linsleyi_. China.

_H. fasciata_. Indian Ocean.

_H. nigrocrinata_. the Krell. Bengal.

_H. dilata_. the Black-Headed Krell. Australia.

_H. subcineta_. Shaw's Chittil. Indian Ocean.

_H. sublunata_. the Chittil. China and Indian Ocean.

_H. mentatis_. the Pale Chittil. Indian Ocean.

_H. occuclea_. the Eye-Head Chittil. Australian Seas.

_A. epytralea_. the Skillet. Indian Ocean.

_H. subannulata_. the Ringed Sea-Snake. India.

_H. aspersa_. the Rough Sea-Snake. Singapore.

_H. corallinae_. the Bluish Sea-Snake. Bengal.

7. _Chitosila._—Rostral broad, transverse; lower triangular; nasal truncated or notched in front; ventral shields flat; head elongate, depressed; eyes large.

_C. incarna_. Indian Ocean.

_C. fasciata_. Indian Ocean.

8. _Korilas._—Rostral broad, transverse; lower triangular; nasal truncated in front; ventral shield broad, convex, forming a slight keeled ridge; the hinder ones with a keel on each side; head short, shelving; scales very large, broad, 6-sided; eyes rather large, over third and fourth labial shields.

_K. Jordanii_. the Krell. Madras.

** Labial shield occupying the front half of the lip; eyes over the fifth or sixth shield; hinder part of the face covered with small scales; ventral scales generally 2-rowed, forming a keeled ridge, some united in pairs in 6-sided shields.

9. _Hydrias._

_H. major_. the Sea-Snake. India; Australia.

c. Body covered with smooth polished imbricate scales; head as large as the body; ventral scales rather large, transverse, smooth, folded together and keeled.

10. _Tomogaster._—With head regular shields; superciliary shields simple; ventral shields entire.

_T. Eydonii_. Indian Ocean.

11. _Stephanohydra_.—Head shields numerous; superciliary shields 3 or 4; ventral shields nicked behind.
S. fuscus, Jukes' Hypopropaxia. Darnley Islands.

B. Head covered with scales, like the body; nostrils surrounded by a small, continuous ring; eyes surrounded by a series of small scales; labial shields small, with a larger series above them; pupil round; ventral shields very small, scale-like, separated on each side of a keeled ridge. The species are all inhabitants of rivers. Acrochordina.

12. Cherneyrus.—Tail compressed, sword-shaped, prehensile; body fusiform, covered with small rhombic scales, with a central tubercular keel.

C. granulatus, the Cherneyrus, Madras. For figure see Livonc. C. annularis. Madras.

13. Acrochordus.—Tail conical, tapering, moderate; body fusiform, covered with cusp-shaped scales.

A. Javanica. Java.

II. Tail conical, tapering. Belly rounded beneath, with more or less broad band-like shields. Rivers or ponds.

A. Head shielded; tail scally beneath; abdominal shields flat, small, 6-sided, with a keel on each side, as if formed of two united scales; nostrils in a ring of small scales; scales keeled. Epytonina.

14. Epyton. E. tentaculata, the Epyton. [Epytow.]

B. Head shielded; tail with two series of shields beneath; nostrils between two shields; abdominal shields broad, keeled on each side; scales smooth. Bitiana.

B. hydrostomias. C. Head shielded; scales striated, and keeled or smooth; tail conical, tapering, with two series of shields beneath; nostrils in a ring of a large nasal shield, with a groove to the outer side; ventral shields round (or rarely slightly keeled on the sides): frontal shields 3, rarely 2 or 4, all small. Cerberius.

a. Crown scaly; occipital rudimentary; frontals 4; anterior pair very small.

16. Cerberus.—Scales keeled, striped; hinder labial shield low.

b. Crown shielded; occipital moderate.

* Head distinct, depressed; frontals 4; anterior pair small; rostral rounded.

17. Narina.—Scales smooth; seventh upper labial low, with a large shield over it.

F. Sibolodi. Bengal.

** Head distinct, depressed; frontals 3; anterior transverse; rostral rounded.

† Fourth and fifth hinder labial shields small or divided.

19. Phytophias.—Scales smooth.

P. punctata. India.

+++ Hinder labial large, like others; scales keeled; rostral rounded.

20. Uranocia.—Scales truncated, strongly keeled, striated; eye over fourth shield.

U. angulas. Tropical America.

T. Leoparkina.

22. Tropopias.—Scales ovate, keeled, striated; eye over fourth and fifth shield.

T. Sibolodi, the Chitiea. Ceylon.

23. Myron.—Scales ovate, slightly keeled, smooth.

24. Heliocia.—Scales ovate, polished; of back and tail keeled.

+++ Hinder labial large, like others; scales smooth; rostral rounded.

25. Heliornithia.—Seventh labial large; eye over fourth and fifth labial; lorel distinct.

26. Parania.—The seventh labial large; eye over the third and fourth labial.

F. fasciata, the Wampau-Snake. New Orleans.

27. Hydropla.—The seventh labial large; eyes over the fourth labial; ventral shield broad; body thick; loarel none.

H. Mariti. Brazil.

28. Hygina.—The seventh labial large; eyes over the fourth labial; ventral shield narrow; body slender; loarel none.

H. fasciata. Demerras.

29. Dimodea.—The seventh labial short, small; eye over third and fourth labial; loarel none.

+++ Head moderate, depressed; frontal 3; anterior elongate, erect, between the nasals; seventh smooth; rostral rounded.

30. Forodania.—Scales broad, rhombic; ventral shield rounded; loarel none; eye over third labial.

31. Gerarda.—Scales broad, rhombic; ventral shields rounded; eye over fourth labial; loarel square.

G. bicornis, the Gerard. West Indies.

32. Hipoidea.—Scales narrow, flattened; ventral shields keeled at each end; loarel square.

H. fasciatus. West Indies.

+++ Head indistinct; frontal 4; anterior 4-sided, rather smaller; scales smooth; body cylindrical.

33. Abator.—Body cylindrical; loarel shield none; anterior frontal 4-sided; posterior ocular 2.

A. erythrogrammus, the Striped-Wampum. North America.

34. Radicia.—Head small, conical; body subspherical; anterior frontal very small, triangular; loarel distinct; posterior ocular.

R. Indica. India.

35. Miridia.—Head small, conical; body compressed; frontal plates 2 pairs; loarel none; posterior ocular 2.

M. alumnus. Java.

+++ Head moderate, depressed; frontal shields 2, small lateral; rostral shield angular, high, erect, between frontals and nasals.

36. Ficosia.—Head small; rostral plate large, produced between the frontal, angular and recurved in front.

F. cinnamomea. Mexico.

+++ Head small; frontal shields 2, transverse, band-like; rostral triangular, subangular.

D. Head covered with small scales; tail with one row of shields beneath; abdominal shield broad, rounded, smooth; nostril in a shield, anterior, subabradal; scale granular, with rows of keeled scales. Xenodermias.

38. Xenodermias. X. Javanicus, the Goniote. Java.

Dr. Gray says, "The separation of the specimens of this family into species and genera is attended with great difficulty; the form and number of the shields of the head, lips, temple, and chin are liable to great variation, not only in the
different specimens, but often in the two sides of the same individual. The two ventral series of scales are, in the same specimen, sometimes separate, and at other times united into a shield; and many specimens have a series of small triangular shields on the edge of the lips, between the sutures of the lip-shield, not found in other individuals of the same species.

The distribution of the colours on the body appears to be one of the most constant characters of the species; but this becomes less distinct in the older specimens, and is often lost in the specimens that have been carelessly or long preserved in a museum.

The existence of this family of Water-Snakes has undoubtedly given rise to the notion that a large Ophiophis, which meets the popular view of a Great Sea-Serpent, exists. In all cases however the reports of the existence of such a creature have been traced to the capture or sight of some other animal, or to the exaggerated representations of some other natural object. The Hydroidae amongst the Ophidiidae are of comparatively small size, seldom equaling the Boidae in this respect, and falling far short of the enormous dimensions popularly attributed to the Great Sea-Serpent.

HYDROIDAE. [Mineralogy, § 1.]

HYDROCYON, a genus of Fishes belonging to the Malacopterygi Abdominales. The species are very numerous. They have the point of the muzzle formed by the intermaxillaries, the maxillaries and premaxillaries; the eye-scales being large, the eyes, and completing the mouth, the tongue and vomer smooth, the jaws with conical teeth, and the large suborbital covers the cheek like an operculum.

A large number of species inhabit Brazil. They are also found in the Nile.

HYDROIDA, a name given to a section of the order Polyptera, embracing forms resembling the fresh-water Hydro in the simplicity of their organisation. The following is Dr. Johnston's arrangement of the families of British fishes referred to the Hydroidae:

- O irises or bulbes naked, bud-like, protruding from the bases of the tentacula.
- Tubulifera, Ehrenberg (Tubulicola, Linnaeus; Tubulicola, Johnston; Les Tubulaires, Van Beneden).

Family 1. - Polyidae, or with only a radium polypidom.

Corynidae.

† Polyidae naked.

The tentacula with globose tips. Corynetica. The tentacula filiform. Cordophyra.

Family II. - Polyptera fistulosa; the tentacula whorled. Tensadica.

† The tentacula in a single whorl. Evistocordaria. + The tentacula in a double whorl.

** Irises in the form of a horned cups or vesicles scattered on the polyopidoms, and deciduous.

Sertoliadina, Ehrenberg (Sertoliadina, Linnaeus).

Family III. - Cells of the polyidoms. Sertoliadina.

† Cells biserif.

+ Cells uniserial.

The branchlets plumose or pectinate. Plumaria. The branchlets whorled. Antennularia.

Family IV. - Polyptera-cells on ringed stalks. Camp catalogueadica.

** Polyptera propagating by buds and ova, which develop themselves on and in the body of the parent.

Hydrina, Ehrenberg (Hydra, Linnaeus; Hydra, Johnston). One genus only. Hydra.

HYDROPELITIDAE, Watershields, a natural order of Exogenous Plants (Cochlospermum of Torrey, Gray, and Lindley). The species are aquatic plants, with floating peat-like fronds. Flowers solitary, yellow or purple. Sepals 3 or 4, coloured inside. Petals 3 or 4, alternate with the sepals. Stamens definite or indefinite, hypogynous, arising from an obscure torus. Anthers linear, turned inwards, continuous with the filaments. Carpels 2 or more, terminated by a short style. Ovules numerous, pendulous. Fruit indehiscent, tipped by the hardened style. Seeds definite, pendulous. Embryo minute, 2-lobed, enclosed in the fleshy sac of the amnion, at the apex of the nucleus, and external to an integument of fleshy albu men. There can be no doubt of the near relationship of these plants to the Water-Lilies. They are American water-plants, found from Guaymas to New Jersey, and also on the coast of Australia beyond the tropics.

Hydroptilus possesses is said to be nutritious, but slightly astringent. The leaves are employed as a remedy for phthisis and dysentery.

HYDROPONITE. [Mineralogy, § 1.]

HYDROTALCITE. [Mineralogy, § 1.]

HYMENOPHYLLEAE, a family of Ferns including the British genera Hymenophyllum and Trichomanes. The fronds consist of branched veins, each accompanied throughout by a membranous wing or margin; a cluster of capsules, set on one side of the leaf, which project beyond the edge of the leaf, the cluster being enclosed in a kind of cup-like involucre.

I. Trichomanes has the on an elongated filiform receptacle within a cup-shaped involucre of the same texture with the frond.

T. radiata, Babington, the Brittle-Fern (T. spectabilis, Wildenow), has fronds three or four times pinnatifid, glabrous; segments uniform, linear; involucres solitary, in the axis of the upper segments; some at first included, ultimately very prominent. The frond in fact consists of hard wiry branched rachis, each furnished throughout with a rather membranous wing. Rhizome black, downy, very long. Fronds arranged along the margin, divided, from 4 to 8 inches long. Involucres scarcely winged.

This is a very interesting fern, on account of its beauty, its rarity, its susceptibility to injury from exposure when in cultivation, and its entire absence from all European countries or islands, with the single exception of Ireland. In texture as well as in scent it resembles some of the marine Angio, and it has been observed to assume a life-like appearance on being immersed in water after being kept perfectly dry for years. It appears at this present time not to be found nowhere but in Ireland, though formerly it is said to have grown at Bell Bank, in Yorkshire. It has been lately supposed by some botanists that there are two Irish species of Trichomanes, the Killarney and the Glouin Carnagh plants. Mr. Newman believes it to be merely a variety of T. spectabilis, and calls it T. s. Andrewsii. It differs from the former in having lanceolate fronds and winged involucres. It is found in very damp shady places. No other fern will thrive well in a case with the Trichomanes, the treatment required for one being destructive to the other. The Trichomanes will live or even grow luxuriantly in a glass with other ferns, but will never attain a vigorous state of growth.

II. Hymenophyllum has the theca on a narrow subulate receptacle, within a 3-valved involucre of the same texture with the frond.

H. Tunicaeformes, the Tunicate Filmy Fern, has pinnae fronds; pinnis distichous; segments linear, undivided, or bifid, spinoso serrat; involucres compressed, spinoso serrat; rachis broadly winged. It is slender and delicate, the rhizome very long and thread-shaped. Pinnae, rachis, and involucres in the same plane. Valves of the involucres adpressed throughout the greater part of their length, slightly gibbose at the base. It is found amongst moss and in shady places, on the surface of rocks and stones, in many places in England, Wales, and Ireland. This plant is the Trichomanes Tunicaeformes of Linnaeus, very rare, and named after the resemblance of the stem to the Tunicaeformes of Linnaeus, the rhizome. It is found amongst moss and in shady places, on the surface of rocks and stones, in many places in England, Wales, and Ireland. This plant is the Trichomanes Tunicaeformes of Linnaeus, very rare, and named after the resemblance of the stem to the Tunicaeformes of Linnaeus, the rhizome.
values of the involucre are convex or gibbose throughout, touching only by their edges, which are quite entire. The range of this species seems to be much more extensive than that of Heracleum maximum, and it appears to be a more northern species, and generally to prefer a greater elevation; still the two plants are often intermixed, particularly about the waterfalls in the vicinity of Killarney, and it is frequent to distinguish the one from the other.

(Newman, British Ferm.)

HYOSCIAMA. [CHEMISTRY, S. 1.]

HYPERURIC ACID. [CHEMISTRY, S. 2.]

HYPOXIDACE. Hyposid, a natural order of Endogonium. It is a tuberous or fibrous perennial root. Leaves always growing from the root and crown, nowhere else, linear entire, plaited, of a dry texture,

Scapes simple or branched, occasionally very short. Flowers complete, hermaphrodite. Perianth pedicellate, adhering to the ovary; claws of the segments of the perianth; filaments distinct; anthers turned inwards, 3-celled, erect, opening lengthwise. The number of the petals of this order is very considerable. Those that are known inhabit the Cape of Good Hope, Australia, the East Indies, the tropics of America, and the warmer parts of the United States.

The roots of Curculigo orthophora are somewhat bitter and aromatic, and are employed medicinally in India. The tubers of C. stevens are eaten in the Marianne Islands; those of Hypoxis rostrata are employed by the aborigines of North America in healing ulcers and against intermittent.

I

IBALIA. [GALLOISH.]

IBAIL, IBRAILOW, or BRAILLOW, a large town in Wallachia, is situated on the left bank of the Danube, 15 miles S. from Galatz, 103 miles N.E. from Bucharest, and has about 20,000 inhabitants. It stands near the large island, and is the chief shipping port of Wallachia, whence the corn and other products of that principality are exported. The town has of late years risen rapidly in extent and importance. Its population in 1838 was estimated at only 6000. The harbour, formed by an arm of the Danube, is sheltered by an island. There are extensive granaries and warehouses in the town. Between 600 and 700 vessels enter and leave the harbour annually. Many of the inhabitants are engaged in the sturgeon fisheries of the Danube. In the war between the Turks and Russians in the 18th century, the town was more than once besieged and taken by the Russians, who burnt it in 1770. After the peace of Kutschuck-Kainardji in 1774, the town was strongly fortified in the European manner; but the Russians took it again in 1829, and demolished its defences. It was restored to Turkey by the treaty of Adrianople.

ICARIAN SEA. [EGIAN SEA.]

ICTERIA. [MRULID.]

ICTINIA. [FALCONID.]

ID. [L.]

IDRIALINE. [CHEMISTRY, S. 2.]

IERAX. [FALCONID.]

IGNATIA, a genus of Plants belonging to the natural order of Capsaicaceae. The species of this genus, F. amara, yields the St. Ignatius’s Beane of India, under the name of Papeata, they are said to be a remedy for cholera. No proof has been afforded of their efficacy in this disease, and Dr. Lindley (Vegetable Kingdom) says that convulsions and giddiness are known to follow their exhibition when given in an over-dose.

ILICIN. [CHEMISTRY, S. 1.]

ILKESTON. [DERBYSHIRE.]

ILMINSER. [SOMERSETSHIRE.]

ILSEY, EAST (BERKSHIRE).

*IMPERATORIN. [CHEMISTRY, S. 1.]

IMPROVEMENTS. [PUBLIC. PUBLIC IMPROVEMENTS.]

INDIAN EMPIRE. The British Empire in India now extends from the Indus on the west to the Tenasserim Provinces and the Eastern Straits Settlements on the east, and from the Himalaya Mountains and the frontiers of Nepal on the north to Cape Comorin on the south. Under the head Hindostan an ample description has been given of the whole of that great peninsula, including the Panjlah, Goojerat, and the island of Cutch. Sipsa is described separately [SIND, S. 1.], as are also the Tenasserim Provinces [Tenasserim], and the Eastern Straits Settlements [Malacca; Perak (979); Py. S.] (S.)

The administration of British India is now under the Governor General of India in Council (who is Governor of the Presidency of Bengal), the Lieutenant-Governor of Bengal, the Lieutenant-Governor of the North-Western Provinces, the Governor of the Governor of Madras, and the Governor of the Presidency of Bombay. A Return furnished by the East India Company, and presented to the House of Com-

mons, July 30, 1867, gives the following summary of the areas and population of the various states comprised under these governments:

**BRITISH STATES**

**FOREIGN POSSESSIONS.**

| French Possessions | 1066 | 28,263,692 |
| Portuguese Possessions | 1056 | 11,326,103 |
| **Total of Foreign Possessions** | **1254** | **40,133,933** |
| **Total** | **1,466,676** | **180,882,234** |

The total revenue of British India for the year ended April 30, 1866, was 25,891,399l.; the total expenditure was 39,854,092l., showing an excess of expenditure over income of 972,791l. The total amount of the public debt bearing interest, April 30, 1866, was 48,014,941l., on which the annual amount of interest was 2,979,031l.,

The total value of the imports in 1864 from British India into the United Kingdom was 10,672,576l., and the total value of the exports thereto, being the produce and manufactures of the United Kingdom, was 2,127,636l., exclusive of exports of foreign and colonial produce valued at 423,732l.

Previous to the breaking out of the great mutiny, the army of the British government in India, including her Majesty’s troops and the Company’s European and native troops of all arms, consisted of 209,999 men; namely, Queen’s troops, Europeans, 9,460; Company’s troops, Europeans, 19,928; native troops, 269,591. The contingent troops of the native states, commanded by British officers, and available under treaties, by which it is agreed that they shall be under the superintendence of British officers, amounted to about 33,000 men.

The Indian navy consists of about twelve steam-vessels of war and transports, and about the same number of sailing vessels, armed with guns, besides a steam-boat for inland navigation.

The history of Hindostan, and the origin and progress of the East India Company are narrated under Hindustan and East India Company. Further historical details are given under Afghanistan, S. 1.; BOMBAY, S. 1.; and Travancore, S. 1., in which last article the narrative is brought down to the date of the treaty of Lahore, March 9, 1846.
March 14. Chuttar Sing, Shere Sing, and the principal chiefs of the Sikhs, together with 16,000 men of the Sikh army, surrender, with all their arms and 41 guns, to Major-General Gilbert, at Bawul Pundee.

March 29. Proclamation by the governor-general, announcing the annexation of the Punjab to the British possessions in India, and the disposal of the Raja of Lahore, retires to Poonah, on a pension of 40,000L a year.

May 6. Sir Charles Napier arrives at Calcutta as Commander-in-Chief.

September. Kohuraj having been condemned to death in August, for the murder of Agnew and Anderson, is sentenced to transportation for life.

850.

February 27. Sir Charles Napier, by a general order, disbands the 96th Bengal Native Infantry, for mutiny.

July 2. Sir Charles Napier resigns his office of Commander-in-Chief, and arrives in London, March 19, 1851.

1851.

January 28. Death of Bajee Rao, ex-Peishwa of the Marathas, at Bithoor. He enjoyed, by treaty, June 13, 1817, and June 1, 1818, a pension of eight lacs of rupees (80,000L) a year.

August 9. The last of the Bajee Rao's brother, was adopted by his uncle as his heir, and on the death of Bajee Rao, claimed the continuance of the pension, which was refused by the Supreme Government of India, and the refusal was confirmed by the Court of Directors.

September 1. Prince of Wales Island, Singapore, and Malacca, formed into a separate government, independent of the Supreme Government of Bengal.

1852.

January 4. The viceregy of Rangoon erects stockades and batteries, to prevent the British vessels from communicating with the shore or leaving the harbour. The British commodore destroys the batteries, and forces the passage of the river Irawaddy.

April 5. Maribah stormed by the troops sent from Hindustan.

April 14. Rangoon stormed and captured by General Goodwin.

October 9. Prome recaptured.

December 3. Pegu invested by a Birmese army. A British force of 3,400 men sent from Rangoon defeats the besiegers, and relieves the garrison.

December 20. A proclamation of the Governor-General of India annexes the province of Pegu, which formed a part of the Burman empire, to the British possessions in India.

June 20. Proclamation by the Governor-General of India announcing the termination of the war with Birma.

The Charter of the East India Company, granted in 1833, being to terminate in April, 1854, an Act was passed, August 20, 1853, "to provide for the government of India." The following is the substance of the most important clauses:—

August 20. Act 16 & 17 Vict. c. 95. 1. Until Parliament shall otherwise provide, the British territories in India are continued under the government of the East India Company. 2. After April 1854 there are to be only eighteen directors of the said Company, any ten of whom are to form a Council. 3. The Crown is to appoint six of the directors. 9. Six of the twelve elected directors must have resided at least ten years in India, as members (sec. 3) three of the six appointed by the Crown. 10. The person appointed by her Majesty to be Commander-in-Chief of her forces in India is also to be Commander-in-Chief of the Company's forces.

December 11. Declared the territory of Nagpoor, whose territories were then added to the British possessions in India.

1855.

March 31. Treaty with Dost Mahomed, who is afterwards re-instated on the throne of Cabul.

February 7. The Governor-General announces by a proclamation the deposition of the king of Oude, and the
annexation of the kingdom of Oude to the British possessions in India. The King of Oude is granted an annual pension of twelve lacs (120,000L.),

February 29. Viscount Canning assumes office as Governor-General, in place of the Marquis of Dalhousie, who arrives in England, May 13. For a notice of the dispute between the British and Chinese authorities at Canton, see China, S. 2.

1857.

The year 1857 is sadly distinguished by the mutiny of the native regiments in Bengal. In January, February, March, and April, there were mutinies of single regiments at Barrackpore, Berhampore, and Lucknow, which were suppressed; but on the 10th of May the 3rd regiment of Bengal cavalry broke out into open mutiny at Meerut, and was joined by the 11th and 30th regiments of infantry in committing murders and appalling atrocities, they marched to Delhi, where they were joined by other native regiments, and where similar acts of barbarity were perpetrated. There the mutineers fixed their head-quarters, and the Old King of Delhi was proclaimed Emperor of Hindustan. Other native regiments broke out into mutiny at various places, but were mostly disarmed and dispersed, till the native army of Bengal had ceased to exist, at least as the soldiers of the East India Company.

May 10. 11. Mutiny at Meerut, and march of the mutineers to Delhi.

May 11. Mutineers arrive at Delhi, and are joined there by three native regiments of infantry and a battalion of infantry. Lient. Willoughby blows up the magazine, containing large quantities of ammunition, and escapes.

May 12. King of Delhi proclaimed Emperor by the insurgents.

May 13 to May 31. Mutinies at various places.

May 27. General Anson, the Commander-in-Chief, with a body of British troops, arrives at Kurnool, on the road from U&oelig;dorp to Delhi, and dies there of cholera. He is succeeded in the command by Sir Henry Barnard.

May 31. Mutiny at Lucknow of three native regiments of infantry and one of cavalry. They are attacked by the British under Sir Henry Lawrence, and dispersed.

June 5. Mutiny at Allahabad. The Europeans secure themselves in the fort, where they are besieged.

June 6. Mutineers under Nana Sahib attack Sir Hugh Wheeler's small force in their entrenchments at Cawnpore, but are driven back.

June 8. Sir H. Barnard enters the cantonments before Delhi with about 4000 troops. He encourages himself on a ridge in front of the Cashmere gate of the city.

June 10. 19. Mutinies at various places.

June 26. 27. Hugh Wheeler having been wounded in making a sally on the 20th of June, dies on the 21st; the small force at Cawnpore surrendered by capitulation to Nana Sahib. On the 17th of June they embarked in boats, but were fired upon and fully all murdered.

July 2. Sir Henry Lawrence, wounded by a splinter from a shell which was thrown into the room where he was seated, at Lucknow, died on the 4th of July. He was succeeded by Colonel Legis in the command of the European force, which maintained itself in the Residency and fort.

July 5. Sir H. Barnard dies of cholera before Delhi, and is succeeded in the command by General Reid.

July 7. General Havelock marches from Allahabad towards Cawnpore, with 3000 Europeans, and 300 Sikhs.

July 12. General Nicolson, with the Bombay flying column route the mutineers at Sealcote on his road to join the force at Delhi.

July 16. General Havelock defeats the insurgents under Nana Sahib before Cawnpore.

July 17. Nana Sahib blows up the magazine, and retreats to Bithoor. General Havelock enters Cawnpore.

July 19. General Havelock attacks Nana Sahib at Bithoor, driving him, takes 30 guns, and sets fire to the place.

July 22. General Nicolson, obliged to rely upon the small force he had from illness, is succeeded in the command of the force before Delhi by General Wilson.

August 2. The Maha-Raja Gholab Singh dies at Cashmere.

August 10. General Nicholson arrives at the camp before Delhi in advance of his column, which arrives in a day or two.

August 16. General Havelock, operating with his small force against the insurgents between Cawnpore and Lucknow, gains his ninth victory.

September 14 to 20. General Wilson, having received reinforcements and a siege-gun, takes Delhi by assault, the fighting being maintained in the city from the 14th to the 20th. On the 18th the British forces had entire possession of the city of Delhi.

September 26. General Havelock, accompanied by General Ostram, with 3000 troops, arrives at Lucknow and relieves the Europeans besieged in the Residency, but is unable to form a siege battery.

October 27. Sir Colin Campbell, having been appointed Commander-in-Chief, leaves Calcutta on his route to Cawnpore.

November 2. Sir Colin Campbell arrives at Cawnpore.

November 13. Sir Colin Campbell, with about 13,000 troops, commences the attack on the rebels at Lucknow.

November 17. Sir Colin Campbell, after a series of operations and some severe fighting, forces his way into the Residency at Lucknow.

Sir Colin Campbell, having remained two or three days, evacuates the Residency at Lucknow, and by a well-derided feint, brings away the whole of the besieged garrison, with all the sick, the women, and children, without the loss of an individual. The rebels are placed in security in the forces of Alambagh, about three miles from Lucknow.

December 7, 8. The Gwalior corps, having secured the line under General Windham, and obtained possession of the town of Cawnpore, Sir Colin Campbell attacks the Gwalior mutineers, and defeated them.

December 10. The defeated Gwalior troops are pursued by General Grant, with cavalry and artillery, and are completely dispersed with the loss of the remainder of their guns and all their baggage, stores, and ammunition.

1858.

In the early part of this year various bodies of mutineers are defeated at different places. In the mean time Sir Colin Campbell at Fдетгагег and Cawnpore, having collected troops to the amount of about 20,000 and about 130 heavy guns, commences the siege of Lucknow on the 1st of March, in connection with the troops of Sir John and Grant and others, altogether, it is stated, amounting to about 50,000 men.

The last mail from Bombay states that the old King of Delhi has been tried, found guilty, and condemned to behead.

Lord Palmerston's late government announced the intention to bring a bill into parliament, for the purpose of transferring the government of British India entirely from the East India Company to the British government, and Lord Derby's late government introduced (March 26, 1858) a bill for the same purpose.

Having now brought down the historical details as far as they are known at the present time (March, 1858), we shall give an account of the chief products of British India, and also of the material progress which has been made there in recent times.

The products of India are as numerous as its surface is diversified and its climate various. The staple products are cotton, indigo, sugar, hemp, flax, oil, opium, maize, rice, and other cereals; besides which there are tea, spices, guns, dyers, and many articles of minor note.

Cotton is the leading feature of Indian agriculture. There is little land, save that which is sterile, swampy, desert, or marshy; and these are the most valuable lands upon the plain country, it forms part of a two years' course; and outside the village walls, hand-weavers have been seen from time immemorial, making the coarse cloth generally worn by the natives. The low consuming situation of India is immense. Economically its growth is confined to no particular limits in the Indian peninsula, for it is found at Travancore, the southernmost part, on the coasts of Chittagong and Arracan, of the Gulf of Cochr, in the Mysore, in the northwestern part of the Panjab and of the Panjab and five million acres are stated in the statistical returns, printed by authority, to be under cotton cultivation in the three
The quantity of raw cotton exported to Great Britain in 1854 was 1,048,308 cwt., valued at 1,641,741L; but if, by means of railroads, the great cotton field of Berar, situated within the dominions of the Nizam of Hyderabad, were placed nearly on an equality in point of facility of transport, with the maritime cotton districts, then a breadth of land sufficient for the growth of a quantity perhaps equal to the present demand of Great Britain, might at once be made available.

The foregoing conditions relating to the province and prospects of Berar are partly, in course of being fulfilled. When the great Indian Peninsula Railway shall be completed from Nagpur to Bombay, and from Nerbuddah to the Indus, will have an outlet to the port of Bombay on one side, and to Mirzapore and the river Ganges on the other; and the railroad which is intended to connect the cities and presidencies of Madras and Bombay, will pass through the cotton districts of Bellary and Belgaum. The cotton of Bundelcund, of the Delhi territory, or of Oude, may be seen to this day, uncultivated and unpressed, passing down the rivers Jamna, the Ganges, and the Indus, in weekly country boats, which drift no faster than the current will bear them along. Still more to be deplored are the efforts required to convey it in country cart, or upon the backs of bullocks, from the great cotton-field of central India towards the sea-coast, or to the banks of the Ganges. From the comparatively small demand of the cotton commerce may be seen struggling among unmade roads, extricated with difficulty from the sands of unbridged rivers, and passing at the rate of 10 to 14 miles a-day, on one side towards Bombay, and on the other to Mirzapore. The best existing remedy, and if one line should not be sufficient, they should be multiplied, until the shipments of cotton from Nagpur shall be as certain and as cheaply effected as they now are from the other parts of India, is the cultivation of the sugar, for the better production of this substance; but if it were planted thickly, so as to exclude the air and light, and with the object of obtaining a long and pliant fibre, there is no reason to believe that this might not be done with much success, as to form a substitute for hemp which is cultivated on a large scale in Russia, Poland, and Italy. The hemp of Kangra, a district of the Himalayas, north of the Panj, has recently acquired some celebrity, having proved on trial superior in strength to even the best Russian hemp. There can be no question with regard to the practicableness of producing hemp of a quality suited to the European market, over vast tracts of country on the lower slopes of the Himalaya Mountains. It has been stated, on good authority, that Himalayan hemp may be raised in England, including all charges, at from 26s. to 31s. per ton, and it is said that its value here would be 35s.

But there are other fibres considered as substitutes for hemp, which are received from India, and have become most important as articles of commerce. One of the principal articles of produce of the Bengal Presidency. It is grown to some extent in the alluvial soil of the North-Western Provinces; but Bengal proper, below the junction of the rivers Jamna and Ganges, is its chief locality. There is a considerable cultivation of the plant in the Madras territory, and in Mysore, the southernmost district of the Panj, as well as in Sinde; but in none of these countries has the manufacture of Indigo had the benefit of that European superintendence and skill, which have brought this dye to such perfection as it has attained in Bengal. The manufacturers have attained a degree of skill which, in a climate favourable to the plant, and backed by the cheapness of labour in Bengal, has enabled them to bid defiance even to the more practised manufacturers of the west. The culture and manufacture, being established, indigo has continued one of the staple products of Bengal. The quantity imported into the United Kingdom from India in 1854 was 64,964 cwt., valued at £1,643,154.

The fibre of Jute, or Jow's mallow, has not been till lately an article of commerce, but for some years it has been much employed in our manufactures. In India it has been long employed for making both cordage and cloth. The material is obtained from two distinct plants, which are known by the names of Jute in India and China, and is styled Chinese Hemp. The fibre is called Jute. The quantity of hemp, sunn, jute, &c., exported from the three Presidencies, but much the largest part from Bengal, amounted in the year 1854 to 570,250 cwt., valued at 200,476L.
Flax, or the linseed plant, has been cultivated in India from the earliest time, not for its fibre, but only for its seed, from which the well-known oil is expressed. It is accordingly sown, not thickly together, as is the case with linen, which is grown for its fibre, but along the margins of fields of other crops, where the soil and climate are equally suitable. It is therefore a crop which the value of the seed depends. But, if in India this plant could meet with some portion of the attention which is bestowed upon it in Russia, Poland, Belgium, Germany, France, Italy, and Ireland, it would be of very important consequence to the flax growers, irrespective of its fibre, as it is already for its seed. The quantity of linseed and flaxseed imported into India during the year 1854 was 196,570 quarters, valued at 601.992.

It has been already stated, that the winters of Hindostan, and of the greater part of the country bordering on the north and north-western provinces, are so temperate as to resemble the autumns of Europe. For a season ranging, according to latitude, from October or November to March and April, all three of the tropics seem to approach to the revision of the seasons. Cultivation of nearly all the European species occupies the soil. Abundance of wheat and barley are grown in this interval, being sown towards the conclusion of the rains in August or September, and reaped in April before the heat sets in. The wheat, however, may be thinned by the birds, and the golden corn; not a single hedge marks the boundary of one field from another, nor even of the numerous village lands; and on an apparently interminable level plain, there is nothing to arrest the eye over this rich expanse, save the great trees and thickest groves which mark the courses of the wells. No wheat comes from India to this country; but rice, which is grown in vast quantities as food for the inhabitants, is also exported to the United Kingdom; the quantity in 1854 having amounted to 1,281,363 cwt., valued at 675,927.

Allusion has just been made to the introduction of the tea plant in India. In 1834 Lord William Bentinck determined upon attempting the cultivation of tea in India. Dr. Royle, Surgeon-Major, in his "Geographical and Agricultural Resources of India," says: "A committee was then assembled for the purpose of submitting to Government a plan for the accomplishment of this object." But so far back as the year 1847, Dr. Royle had drawn attention to this matter, and pressed upon the notice of Government. "The tea plant," he stated, "delights particularly in sheltered valleys, the declivities of hills, or the banks of rivers, where it enjoys a southern exposure to the sun. But it is found also to grow on the rugged tops of mountains; and although it appears to attain the greatest perfection in the mild climate about Nainital, yet it flourishes in the northern latitude of Peck, and in Japan, as well as about Canton, and these places are comprised within the parallels of 20° and 40° north latitude." Dr. Royle says that he believed that that part of the Himalayas, or at moderate elevations, there was a considerable prospect of success in the cultivation of the tea plant; for the different elevations allow of every variety of climate; the soil is well adapted to the growth of the plant; the climate is sufficiently extended, and the natural sites sufficiently varied, to warrant its being beneficially cultivated. Taking the extreme limit, the Himalayas extend over 45° of longitude, but not making more than 10° of northing in its whole extent. Though varieties of longitude no doubt produce difference in climate, yet as this is chiefly influenced by latitude and elevation, it is evident that along the whole extent of this mountainous country, there must be many localities which differ little in latitude and in elevation, and which must consequently resemble each other somewhat, and therefore probably also in vegetation." In the hills of Assam, the tea plant was found to be indigenous. Plants also were procured from China, as well as seeds and cultivators, to carry on the experiments of which it was resolved to make, and when the practicability of producing tea fit for commercial purposes shall have been ascertained, it may be safely left to the enterprise of individuals. This course has been strictly followed. The Court of Directors, and the Government of India, having brought forward the cultivation of tea as a successful issue, have handed over its further extension to a private company, who are carrying it forward with great advantage.

The directorate of this Company, employed in the cultivation and preparation of tea in Assam, for the half-year ending the 31st March 1856, amounted to 19,655.

In the Kungdras district, quite at the other extremity of the British territory, still on the lower slopes of the Himalayas, in the Marree Hills, and in Ghurwal, Kumaon, and the Darya Doon, and Darjeeling, similar successful experiments in tea culture have been made, and annual production of excellent tea takes place. Its cultivation by the natives has been encouraged by grants of land on good terms, and so much care bestowed on the production of a saleable tea, that hope, that they will succeed except under European superintendence. It can only, therefore, be expected that tea will be produced over the great extent of the Himalayan range which bounds Assam and northern India, and which has been occupied by other Indian companies, like that which has succeeded in Assam. Besides the Assam Company, another has been recently established for the growth and manufacture of tea in Darjeeling, a part of the Himalayas to the eastward of Nepay. The Assam Company was formed in 1798, and in the United Kingdom in 1854 was 286,381 lbs., valued at 32,943.

Only a brief allusion will be made to Opium, for although it is a native of the tropics, its cultivation, in the United Kingdom, is not a free product of its soil. It cannot be cultivated except by.permission of the Government, who retain the monopoly of it in their own hands, and discourage, by heavy duties, any extension of its production. In the case of a植物, the utmost care is expended, and the best care with which it is maintained by these restrictions, is probably a benefit to that portion of the human family which is addicted to its use. The profit realised by the Government by its sale, exceeds three millions sterling. There is one fact in connection with this subject, which is worth recalling. Out of every pound of opium from which it is prepared, does not appear to be indigenous to India. It has been found nowhere in a wild state, but it is a plant which is extensively distributed over both the European and native provinces of India. The plants cultivated in the Bengal Presidency, chiefly in Malwa, and in Central India, is due to the natives alone, unaided by science or European superintendence. The selection of soil and climate under which it has been found most to thrive, with the circumstances of the soil, that is, the dryness necessary to its cultivation. Nature does the rest, ordinary care only being necessary, to collect the milk and secretions, which are extracted from the capsules of the plant, and to evaporate the moisture with which it is mixed, till the residue is sufficiently dry and prepared for use.

With the exception of tin and salt, there scarcely is said to be any export of mineral substances from India. In 1856, the value of the tin imported into the United Kingdom was 52,130.

Several manufactured metals are specified in the tables of imports from the three Presidencies; but the probability is, that these are chiefly re-exports of British goods from the ports at which they were first landed to other places in the Company's dominions. Iron, manufactured, or iron, manufactured, or iron, lead, or any other metal except tin, is yet known among the exported goods from India. Very extensive deposits, however, of both coal and iron are known to exist; and when these two substances can be found in the same country within any reasonable distance of one another, to what extraordinary results may they not eventually lead! In Bardwan, a district of Bengal, an inexhaustible field of coal is known to exist, one of the seams of which has a thickness of thirty feet, and the coal-field has been worked for several years. The inland steam navigation of the Ganges has long been supplied, and much of the coal used by sea-going steamers has come from Bardwan; but its price in Calcutta has not always, having reference to quality also, been equal to the coal from the Assam fields. Coal is also found in the valley of the Nerudder, and in the Tenasserim Provinces; but from neither of these localities has it yet been profitably procured. Vast masses of the iron-ore have been found in the west provinces by the Government of India, and there is an annual export of manufactured iron from that place. The Gwalior iron is well known in the inland trade, so that it of Kangra and Kumaon, which is exported to the iron-ore of the adjacent hills, and there is an annual export of manufactured iron from that place. The Gwalior iron is well known in the inland trade, so that it of Kangra and Kumaon, which is exported to the iron-ore of the adjacent hills, and there is an annual export of manufactured iron from that place.

Google Digitized by Google
mon. Unfortunately no coal occurs, nor is likely to be found within any reasonable distance; but abundance of charcoal can be made from the boundless forests with which the lower slopes of the Himalayas and the plains adjacent to them are clothed.

There are copper mines worked by the natives in several districts of the Himalayas; but the produce is small, and India has never supplied herself with this metal. Brass vessels are common in Europe. No smelting of copper ores is done in India. The manufacture of brass is imported annually at the principal ports of the three Presidencies, to a large amount. The natives of Hindostan have neither possessed the capital nor the skill to mine deeply, and to abstract the riches which he buried in his bed of ore and cover with sand and clay the nation produce of their shallow workings are a mere indication.

The southern portion of the Tenasserim Provinces, from the province and latitude of Tavoy, to the Pakhan river, abounds with deposits of tin, which is found in great proportions in the beds of streams and in hills of disintegrated granite on the plain. It is a pure peroxide of tin, requiring the application only of a moderate heat to produce the perfect metal. The quantity hitherto prepared in the British territory, can be regarded only as an indication of what might be obtained if labour and machinery were duly applied to the task. The extent of tin-working which has been carried on in Tenasserim, has not been by the natives of that province, but by the enterprising and more industrious from the north in the Myanma, and the soil is now beginning to be seen dotted here and there in the forests. They have a smelting establishment at the mouth of the Pakhan river, and the tin is carried away in junka to Penang and Singapore.

Salt is an article of manufacture in India almost exclusively for domestic consumption, the value exported being insignificant. Sufficient has now been said of the most important independent products of India, to show in what her real wealth and value to England consist;—above everything, it has been intended to prove that, in comparison with the actual produce of her soil, all else sinks into insignificance when we contemplate the resources, or endeavour to accede to the wants and necessities of the community. There is no step which has a more direct bearing on this subject than the irrigation of the land by artificial means. There are traces in various parts of the country of works constructed in ancient times for this purpose. Canals of irrigation were formed either from the head waters of some of the rivers as they issue from the Himalayan range, or lower down, where, at one period of the year, they overflow the adjacent plains. In some of the minor hills the head waters were dammed up, and the water formed, from which the discharge could be regulated and distributed when the ground was parched. It has been commonly and with some justice remarked, that to furnish the native cultivator with the command of water is to give him nearly everything he requires to insure his prosperity.

The East India Company, following the example of the Moguls, their predecessors in the government of the country, have greatly extended the means of irrigation in the North-Western Provinces, in the Punjab, and in the Presidency of Madras.

With regard to irrigation canals, the waters of both the Jumna and the Ganges rivers have been freely drawn upon. The country on the right and left banks of the Jumna, from Sutlej to Allahabad, is irrigated on a large scale and may be said to be secure against drought, cultivation now, over a large surface, being entirely independent of the periodical rains. The Eastern Jumna and the Western Jumna Canals, with their branches, are 450 miles in lineal extent. The volume of water available for irrigation from this river, has been calculated at 2,870 cubic feet per second, and each cubic foot has been found adequate for the annual irrigation of 315 acres of land; but as one-third of a district only is named, the Nerbudda. On this basis of calculation, the irrigation, one cubic foot of water per second will suffice for 564 acres of land, equal to about one square mile, so that the canals of the Jumna are supposed to serve for the irrigation of 172 square miles.

The Ganges Canal is a still nobler work. Nearly the whole tract of country comprised between the rivers Ganges and the Jumna, from Hardwar to Allahabad, is included in this large system of irrigation for the North-Western Provinces. The main line of this canal, which was completed, and received water for the first time in 1854, in 256 miles in length. Its extreme breadth is 170 feet, and its greatest depth 10 feet; and, as truly described by the Lieutenant-Governor, "it is a work which stands unequalled in its class and character among the irrigation works of the world. When the canal shall be finished the canal will be about 900 miles in length, and the area which may be irrigated by its waters is stated to be not less than 1,470,000 acres. It is adapted also to navigation, and on that account alone the great empirical value of the Ganges Canal is proved. It nearly equals the aggregate length of the five greatest canals in France. It greatly exceeds all the first-class canals of Holland put together, and it is greater by nearly one-third than the greatest navigation canal in the world. The canal, in all its branches, and the greatest triumphs of the engineering art of which any country can boast. Its total estimated cost is 1,655,545l., of which 1,400,000l. had been expended up to the beginning of the year 1837. In the Punjab a system of similar canals has been projected and partially commenced, to afford the means of irrigation to the greater parts of the tract of country comprised between the rivers Ravee and the Sutlej. With the branches, the total length when finished will be 420 miles, and the cost 500,000l. The head waters, like those of the Ganges and Jumna canals, will be taken from the rivers at a high level, and carried along the slightly elevated ridge which is generally found to exist between two rivers, having a gentle declivity on each side. The Punjab Canal will be of great advantage to the country. But towards the southern part of the Punjab, at and below Mooltan, and on each bank of the Indus, another description of irrigation canal prevails, which is formed by an accumulation of water formed by those rivers, and leading off bodies of water in channels to considerable distances inland. These canals have existed for long periods, and efforts are now being made to restore and bring them again into extensive use.

In the Madras Presidency another system of canals prevails, which is suited to the features of the country. The tract to be irrigated being narrow, in comparison with the extensive plains of the North-Western Provinces, and the body of available water considerably less, it has been found expedient to make the canals of great length across the channels of Godavery, the Cauvery, and the Krishna rivers, so as to store up their waters and distribute them at pleasure during the dry season. These works on the Godavery have cost about 290,000l., on the Cauvery 460,000l., and on the Krishna 150,000l.; and, without doubt, the number of the localities are endless, both in that Presidency and in various other parts of India, where similar works might be constructed with the greatest advantage.

Next in order of importance to the future progress of India, and in a still wider sense than may yet be known, not only with regard to its material interests, but to its social and moral advancement, is the continuous chain of iron roads by which it is to be connected with the whole of the principal and most productive provinces in the Indian Empire will be linked together. Already the natives of every class and caste, contrary to general expectation, unborn of any prejudices, banding together in the same railway carriage, have seized with avidity the advantages of the locomotive train in Bengal, Madras, and Bombay. The opening of the railway for short distances at Calcutta, and the two other Presidencies, has been hailed with acclamation by the whole people, who flocked from their villages for miles to witness the new wonder.

The grand trunk lines now in progress of construction are of great extent. From Calcutta the main line will lead through the entire valley of the Ganges, for a thousand miles to Delhi, with an eventual extension, in the same general direction, across the rivers of the Punjab to Lahore, and perhaps to Peshawur. From Bombay another main line has been commenced, and will stretch nearly across the continent of India at its broadest part, taking the general direction of the Nerbudda, passing down the rivers Konda, Kandiahi, Sauger, and Bundelcund, branching into the great cotton-field of Central India to Nagpoor, and affording an easy outlet for that valuable product, either to be shipped at Bombay, or be transported down the river Nerbudda to Mirapaor to Calcutta. At Mirapaor a junction will be formed with the Bengal line. There is also a line to the northward of Bombay, in order to bring down the cotton from Baroogh, Baroda, and Surat. In Sinde there is a short line undertaken to connect the port of Kurachhee with the
INDUS, which seems to be a first step towards a direct rail-
way, or mixed railway and river steam communication, from
the Panjib to the sea. In the Presidency of Madras, two
trunk lines are projected: one to penetrate the peninsula in
a longitudinal direction, and to connect Bombay, passing
through some rich cotton ground in Darwar and Bellgaum;
the other to strike across to the western coast, having its
other terminus at Madras.

At the beginning of 1857 the number of miles of railway
already opened for traffic at the three Presidencies, and the
extent of each line actually in a state of progress, are as
follows:

<table>

When these grand trunk lines of railway shall have been
completed, a glance at the map will show that, although the
richest districts will have been penetrated, and the principal
cities connected, the 2,896 miles of which they consist, are
but the foundation and groundwork of what will be
ultimately required, before it can be said that India is completely
provided with an internal communication; for, in fact, many of
the inlying districts can be supplied with food, when their
own internal resources may fail.

Inland steam navigation has existed for several years on
the river Ganges, and also upon the Indus; but not by any
means to that extent which even the private trade of Bengal
and the Punjab requires.

The ordinary highways of India is a subject which cannot
be regarded with much satisfaction. Until the period when
Lord William Bentinck governed the country, the subject of
roads does not appear to have attracted much attention from
the State. The communications of the country were in
a most neglected condition, consisting of native wheel-tracks,
or little else. Above Allahabad, and in various other parts,
southernly as well as northernly, a regiment of musketeers,
of relief from one station to another, had to be preceded by
a native guide. This is now altered. Roads, even if
unbridged and unmetalled, exist in almost every district; and
there are three great lines of communication of considerable
length; the earliest begun only in 1836, from Calcutta, and
recently prolonged to Peshawur; this, however, is not yet
completed in parts.

The three grand trunk roads constructed and maintained,
are as follows:

<table>
<thead>

The above average expenditure upon public works of all
kinds in India during fifteen years, between 1827 and 1842,
was 299,732L. In this are comprised roads, bridges, embank-
ments, canals, tanks, and all works of irrigation; but since
1828 the outlay has been much greater, including the sums
spent upon the Ganges and Panjib Canals, and the guaran-
teed interest upon Railway Stock, which must be regarded as
a contribution to public works.

The electric telegraph, which has been recently established
without any expense, and so auspicious in its progress, can scarcely be regarded
as bearing so directly upon the wants and welfare of the
people, as other public works which have been briefly
described. Except inasmuch as it is an aid to good govern-
ment and to the preservation of peace, the rapid transmission
of intelligence from one part of the country to the other, and
as yet slightly regarded by the native community, but when
traffic shall be accelerated by the railways, it will not be
long before the telegraph will be rightly valued. More
than 4,000 miles of telegraphic wire are now set up in India, and
in constant use. The superintendent, Dr. O'Shaughnessy,
availing himself of the executive officers of Government
throughout the country, to set up the posts and to build
pillsars for the support of the wires, and since he has own
trained and furnished the line, and previously prepared and brought
from England, was enabled to complete the communication
between Calcutta and Agra, a distance of 800 miles, in
the course of five months. In fifteen months, all the lines from
Bombay, including the Advertisement on the Indus, from Agra to Bombay, and
hence to Madras, extending over 3000 miles of space, were
ready for use. Other places more distant have since been
embraced in the electric circle, and the average cost of these
4000 miles does not exceed 600L. per mile, although the
physical character of country intervened sometimes to
make it indispensable.

INDIAN TERRITORY, United States of North America,
an extensive tract of country set apart by the Congress
and federal government, for the permanent residence of the various
tribes of native Indians removed from the settled states and
territories of the United States. The Indian Territory is
bounded by the 32° 30' and 39° N. lat., 94° and 106° W. long.,
but the limits are not very strictly defined. It is bounded S.
by Texas; E. by Arkansas and Missouri; and N. by the newly created
Territory of Kansas. The area, as given in the 'Report of the Census'
of 1850, is 157,171 square miles, but this is considerably
more than in previous statements of the area of
what is sometimes called the Indian Territory proper, and
perhaps includes a portion of the country since appropriated
to Kansas. The Indian Territory now contains, at
from 100,000 to 120,000, four-fifths of whom have been transplanted
from countries east of the Mississippi.

In the south-eastern part of the Territory there is a range
of hills of moderate elevation; the remainder is a plain, or
magnificent grassland, undisturbed by any body of
water. But a great portion of the country is prairie ground, and along the rivers
there is a good deal of timber. The country is well supplied
with water, having several good-sized rivers running through
it, or along it, and furnishing in their waters
great wealth of fish. The Arkansas flows through the midst in a
south-eastern direction, and receives in its passage numerous
tributaries, some of considerable size. The chief of these
tributaries is the Canadian River, which also has numerous
tributaries. The Red River originates in Texas and, like the
Kanas, the northern portion of the state; both of these,
as well as the Arkansas, are navigable within the territory
in certain seasons by steam-boats. The country possesses
capabilities for the prosperous maintenance of a large popu-
lace; the middle and far up the rivers, as well as the
larger part of the country, appears to belong to the Lower Carboniferous series
of rocks. On the east are the Upper Carboniferous strata,
or coal-measures, a part of the great coal-basin of Missouri and
Illinois, broken towards the north and northern extremity of
the Cretaceous group of rocks. On the south is a narrow
belt of Lower Silurian rocks, consisting along the Red River
of blue limestone, with eruptive rocks. Coal is not the only
mineral obtained. Both lead and iron are found; and there
are several springs, from which a large number of wells
may be manufactured. The climate is generally healthy. The
northern portions are subject to keen winterly winds from the
Rocky Mountains, and the winters are rather cold; but in
the southern parts the winters are mild, and all the plants
are cultivable which are raised in other parts of the United
States of the same latitude. The soil on the eastern side of
the Territory is generally fertile; the northern parts are well
adapted for grazing cattle. Maize, wheat, and other grains,
produce good crops in almost every place where they have
been tried.

As already said, this large tract of country has been appro-
priated for the permanent residence of the Indian tribes
transported from the settled parts of the United States. It
need hardly be said that they have not turned to full account
the capabilities of the country. But they have shown that
they are capable of steady industrial efforts, and they have
made very considerable advances in civilization. Under the
guidance of missionaries, who have sought amongst them,
and with the assistance of the Commission of Indian Affairs, some of the larger tribes have established
regular governments, legislatures, judicial officers, churches,
schools, newspapers, &c.; have introduced the manufacture
of cloth, and engaged in agriculture, cotton and
many farm and domestic use; cultivate the land with a con-
siderable amount of skill; rear horses and cattle; build
houses; and export to neighbouring states maize, cotton,
hides, &c. By the treaty of removal and settlement, the
federal government furnishes them with blacksmiths,
wrights, and some other mechanics, and at their first settle
1. The Capitolium. The undeveloped axis is here usually enlarged upward, with a fleshly or spongy form, and the more so if the number of flowers is very great. It may be more minutely designated as simple, discoid, cupuliform, lageniform, conical, and cylindrical, as it approaches nearer to one or another form, passing gradually into the spadix. Special varieties are:

**a. The Calathium (Anthodium, Ehrh.; Flos Compositus, Linn.), a many-flowered capitulum, whose single flowers stand in the axis of more or fewer stunted bracts, and are surrounded with one or more circles of sterile bracts, as in the family of the Compositae.**

**b. The Cenannithium, Nees (Hypanthodium, Link.).** Exactly like the preceding in some Oricocaceae. A cup-shaped placenta in Ficus is no distinction, since it is wanting in Drostania; and it exists in some Compositae; the same may be said with regard to the sterile bracts, which are as much stunted in Drostania as they are clearly present in Ficus.

2. The Spikes (Spica) in very various forms. The kinds are:

**a. The Catkin (Amentum), distinguished by the fact that it falls off entire, or by its imperfect flowers.** The male inflorescence of Cupulifera, Salicocoe, Batoulacoe, and some few other plants also is a spadex.

**b. The Spadix, a closely crowded spike, or partially a cylindrical capitulum with fleshly, peduncle; in Araceae, Maiace, and some other Grasses, and in Palmea, in the last of which it is often composed (Spadix Ramous).**

**c. The Cone (Strobilus or Conus), a cylindrical capitulum or solid spike, on which the individual foliar organs become woody scales; as in the Comifera, the Casuarinaceae, the Balatulaceae, and some others.**

**d. The Spikiel (Spicula), the simple inflorescence of the Grasses and Cyperaceae; namely, a few-flowered spike, whose flowers have no bracts, surrounded at the base by one or two sterile bracts (Glume).**

3. The Umbel (Umbella) in the Umbelliferae; when compound of orders of Umbellula (Umbellula). The Raceme (Racemus) occurs in very different forms; it is usual to distinguish in it—

**a. The Corymb (Corymbus), a pyramidal raceme.**

4. The Cyme or False Umbel (Cyme), is a corymb with Inflorescentia Centifraga. That only singular cases are distinguished in this is a proof of the totally unscientific patching together of our terminology. The compound raceme, the compound umbel, and capitulum, with inflorescentia centifraga are all called a Cyme (Cyme), which is contrary to the commonest scientific usage. De Candolle has reviewed and further amplified the term Cyme to the inflorescence of the Boraginaceae, which, on account of the peculiar manner in which it unrolls itself, he terms Cyme Scrophiodes; and he adds the fiction, that the underneath first-blooming flower is really the terminal blossom, and the second, the terminal blossom of side axis, is developed in a disproportionate degree, &c. From the rolling up there is just as little to be deduced as from the same phenomenon in the leaves of Ficus and Cycadaceae. The position of the bracts, as seen in the development, which can alone determine the point, appears to prove that here a one-sided raceme or spike is present, whose unrolling is only a peculiar situation of the buds.

C. Once-Compound Inflorescence.

5. The Cyme or False Umbel (Cyme), is a corymb with Inflorescentia Centifraga. That only singular cases are distinguished in this is a proof of the totally unscientific patching together of our terminology. The compound raceme, the compound umbel, and capitulum, with inflorescentia centifraga are all called a Cyme (Cyme), which is contrary to the commonest scientific usage. De Candolle has reviewed and further amplified the term Cyme to the inflorescence of the Boraginaceae, which, on account of the peculiar manner in which it unrolls itself, he terms Cyme Scrophiodes; and he adds the fiction, that the underneath first-blooming flower is really the terminal blossom, and the second, the terminal blossom of side axis, is developed in a disproportionate degree, &c. From the rolling up there is just as little to be deduced as from the same phenomenon in the leaves of Ficus and Cycadaceae. The position of the bracts, as seen in the development, which can alone determine the point, appears to prove that here a one-sided raceme or spike is present, whose unrolling is only a peculiar situation of the buds.

6. The Spikes of the Grasses (Spica), several spikes united in a spicate arrangement, as in the Grasses; the component spikes are termed Spikela (Spicae).

7. The Umbel (Umbella). Umbels united in umbels; the components are termed Umbellulae (Umbellulae).

Sound terminology would have long ago rejected these words, and exchanged them for Spica and Umbella Composita.

8. The Panicle (Panicula); see No. 11.

None of these remaining combinations deserve special names, and may probably be classed among those mentioned under 9 and 11.

**a. Inflorescentia Centifraga.**

---

**INDIN. [CHEMISTRY, S. 1.]**

**INDIC ACID. [CHEMISTRY, S. 1.]**

**INFLORESCENCE. [INFLORESCENCE.]** The following is a list of inflorescences and their names, from Professor Schleiden's 'Principles of Scientific Botany.'

A. The Solitary Flower, as terminal or axillary-flower (Flos Solitarius, terminalis vel axillaris). The latter may be situated in whorls, and then form a Verticil (Verticillus).

B. Simple Inflorescence.

**a. Inflorescentia Centifraga.**
9. The Cyme or False Umbel (Cyma): see No. 5 and No. 14.
10. The Anthela: see No. 16.
** Mixed or Heteromorphous. **
* Inflorescence Centrifuga. *

See No. 14. ** Inflorescenta Centripeta. **

See No. 11. ** D. Many-Times-Compound Inflorescence. **
* Inflorescencia Centripeta. *

11. The Panicle (Panicula), every many-branched inflorescence in Grasses universally, and otherwise wholly in developed pedicels.
12. The Thyrsus (Thyrusa), a panicle, with very short pedicels; with the exception of Grasses, found almost universally.
Both terms are applied also to once-compound inflorescences. De Candolle uses the term Thyrsus for those in which Inflorescence Centrifuga and Centripeta are mingled; others differently; all arbitrarily.
13. The Anthus, an inflorescence that has the kind of aspect of that of the Amaranthus caudatus or the Cheno-
dioica. **
* Inflorescencia Centrifuga. *

14. The Cyme (Cyma), also in manifold combinations, in which we do not consider whether the side ramifications follow the Inflorescence Centripeta or Centrifuga in longer pedicels.
15. The Fascicle (Fasciculus), a manifold compound cyme, with short pedicels, and rather crowded.
16. The Anthela, all kinds of inflorescences in the Juncaceae and Cyperaceae.
17. The Glomerule (Glomerum), many inflorescences that appear almost like a capitulum, and consist only of ill-formed, imperfect flowers, as in some Cheno-dioicaceae, Urticaceae, and Juncaceae.

We subjoin Professor Schiedel's closing remarks:—

"I have many of such with my faculties to draw for myself the sad conclusions which the preceding survey affords; and I think that I have not to defend myself to any one who is acquainted with our literature, against the charge that the foregoing is a frivolous vagary of my humour. Rather first attempted a scientific development of the inflorescence. No one that I know of has followed him except Lindley. Physiologists seem not to have accounted it of sufficient importance. Systematists have too much to do with their herbaria, and it is much easier to coin a new word than to study minutely the progressive development through a large series of plants. For the sake of those unacquainted with these matters I will insert the following examples:—In Lotus corniculatus, Koch ('Syn. Fl. Germ.') has a Capitulum, Kuntz ('Fl. Berol.'). For Chloris purpurea, Koch ('Fl. Excurs.') actually a Fasciculus. To Eriophorum vaginatum Kuntz gives a Spica; Koch a Spicula. For Cadinum Marius Kuntz has Umbella Axillariae at Terminalia; Koch, Anthema Axillarea et Terminaliae; Reichenbach, Cyma Axillarea et Terminalia; in Iodeia sanguinea Koch has Spiculae in Fasciculum aggregatia; Kuntz, Spiculae Conglomeratae. I have here omitted the French and English botanists, or the matter would have been still more glaring."

Huxley. At the time the classification given under the head Polyostraca was drawn up, the distinctions that limit the vegetable and animal kingdoms were less perfectly understood than at present. One of the first members of this group of organised beings that was withdrawn from the animal kingdom, was the Dendritica, which are now generally recognised as plants. [Dendroica, S. 2.]
The group of Pseudopoda'ta tortuosa must also be placed amongst doubtful creations, although many physiologists do not hesitate to group them amongst plants [Diatomaeces, S. 2], whilst the groups Monandria and Polyonema have recently undergone the most searching investigation, with the result that many of these forms are more decidedly vegetable than animal in their character. Some have even gone further than this, and have joined in the American Journal of Science, for 1842, thus writes to Mr. Dana:—"You may remember a paper I read at the meeting at Cambridge, United States, in August 1849, in which I showed that the embryo which is hatched from the egg of a Planaria is a genuine polygastric animal—
ment and evolution of a Tricodium, a discovery which
Ehrenberg has attempted to explain by the supposition that the
live forms of the Actino-phyceae, in the formation of the
pristine condition. The enucleated solid is gradually dissolved, and
a scan of the change of appearance from time to
time, if entirely soluble, so for instance an Infusoriun, the
space in which it is contained contracts as the dissolution of
the material contents proceeds. Should there be however an
indissoluble residue (a membrane composed of cellulose, a portion of chitine, a shell of a
Lymnaea, or case of a rotifer, &c.), a passage for its exit is
formed, and it is expelled by renewed contractions of the
homogeneous mass, which is then thrown out in the form of
a small ball, so as that which the mould followed in its introduction.
The passage and the opening through which the expulsion
was effected disappear again without leaving any trace."

In the Actinosperms, the whole body is thrown into the
shape of the creature which inhabits the shell of the large family
known as Foraminifera, and Dujardin suggests that the
encircled forms of Dictyophor and Acrora are transitions to the
more decided forms of Foraminifera. Hence he proposes the
formation of several forms of the Ehrenberg's Infusoria,
with the Foraminifera or Polyhalmia, under the term
Ethereopoda. Little therefore is left to say of what may be
regarded as true Polygastria. They all appear to have a
distinct mesaxonic arrangement of the body, and this is
usually surrounded by vibratile cilia, as is seen in
Monas atomus and Lewesopus patula. These cilia
apparently bring the food to the mouth of the animal.
An anal orifice is described by Ehrenberg in the majority of
these animals, which is usually ciliated: onwards, and
carmin or indigo (a writer in the 'Microscopical Journal'
recommends the red pigment which lines the cornea of the
common house-fly) is introduced into the water in which
they are contained, the transitory body of the infusorium
is speedily seen to be studded with coloured globules
consisting of an aggregation of the particles of colourless-matter.
Ehrenberg regarded these globules as distinct sacs, which he
supposed were given off from a central intestinal canal, as
seen in Lewesopus patula. A single line passed from many
stomachs, he gave them the name of Polygastria
(many-stomached). It is however still a question as to
whether in any case these masses are contained in a distinct
sac. The whole body of the animal is often covered
with vibratile cilia, and it is to the constant action of these
organs that the varied movements of these animal-sac are
due. The movements thus effected are perfectly automatic,
and in no way connected with any intelligent conscious-
ness. All the movements of the animal are due to cilia, as the whole of the tissue of the animal is observed to
contract in Amaba, Amphileptus, and the stalk of the
Verticella.

Although Ehrenberg has described a complicated apparatus
for reproduction, no instances of conjugation are recorded
amongst the true Polygastria. Their modes of multiplica-
tion are by fission and gemmation. In a large number of
cases a simple division of the unicellular organism into two
equal parts takes place. This process goes on so rapidly
that, according to Ehrenberg, a single Paramecium could
produce 268,000,000 of cells in a single month. From anal-
ogy we must suppose this process would not go on continu-
ously, and, as in plants, we must regard the separate cells
thus produced as belonging to the same individual. Further
observation is probably only needed to demonstrate the
existence of a union of two cells—a sperm cell and a germ
cell—as is now known to be almost universal in the vegetable
kingdom. In this case it will be seen, that it is not improbable that one of the
modes by which these beings are enabled to spring suddenly
into existence, is the production of winter-eggs, or reproduc-
tive bodies of a kind that will resist the influence of an absence of
moisture from the spot in which they ordinarily abound.

The true Polygastria seem universally diffused. Wherever
organic matter exists in a decomposing state, there they abound.
They exist in incredible numbers in the waters of
the ocean, in rivers, lakes, ponds, pools, and ditches. They
are found in abundance in the body cavities of the
animals, and not unfrequently in the blood of the
man. Wherever the organic elements, carbon, hydrogen,
nitrogen, and oxygen, are capable of uniting to form water,
carbonic acid, and ammonia, there they may be expected to
be found. In general, the nearness of the
abundance of the
form to the animal, seems to determine the forms they assume. One set of
forms inhabits salt water, another fresh. Every miner
spring has its peculiar inhabitant. The sulphureous springs of the Pyrenees, the chalybeate waters of the Rhine, the siliceous, calcareous, and alumminous waters of Europe, all contain them. They are found with the red snow of the Alps and the poles, and with the Conferens thermales of the hot springs of Baden. They are almost everywhere accompanied by plants. Perhaps it would be wrong to call any beings animals that are not found feeding on plants, as it seems to be a law of organic existence that plants should support on mineral matters, and animals on organised matters. When asked of these beings, Professor Owen gives the following reply: "Consider their incredible numbers, their universal distribution, their insatiable voracity, and that it is the particles of decaying vegetable bodies which they devour and assimilate. Surely we must in some degree be indebted to those ever-active invisible scavengers for the salubrity of our atmosphere. Nor is this all: they perform a still more important office in preventing the gradual diminution of the present amount of organised matter upon the earth; for when this matter is dissolved or suspended in water, in that state of comminution and decay which immediately precedes its final decomposition into the elementary gases, and its consequent return from the inorganic world, these wakeful members of nature's invisible police are everywhere ready to arrest the fugitive organised particles and turn them back into the ascending stream of animal life. Having converted the dead and decomposing particles into living tissue in their own bodies, they become the food of large Infusoria, as the Rotifer, and of numerous other small animals, which in their turn are devoured by larger animals, as fishes; and thus a pabulum, fit for the nourishment of the highest organised beings, is brought by a new route from the extremity of the realm of organic matter.

"There is no elementary and self-substantive organic matter, as Buffon taught; the inorganic elements into which the particles of organic matter pass by their final decomposition, are organically recomposed and fitted for the sustenance of animals through the operations of the vegetable kingdom. No animal can subsist on inorganic matter. The vegetable kingdom thus stands, as it were, between animal matter and its ultimate destruction; but in this great office, plants must derive most important assistance from the Poly-gastric Infusoria. These invisible animalcules may be compared, in the great organic world, to the minute capillaries in the microcosm of the animal body, receiving organic matter in its state of minutest division, and, when in full career to escape from the organic system, turning it back by a new route towards the central and highest point of that system."

INGHIRAMI, CAVALIERE FRANCESCO, a distinguished Italian archaeologist, was born in 1772, at Volterra in Tuscany. From the completion of his education he devoted himself with unwearied diligence to the study of ancient art. He wrote several papers in the artistic and antiquarian journals, which secured for him a high rank in some of the learned art authorities; but the work which acquired for him a European reputation was the splendid publication entitled 'Monumenti Etruschi,' of which the first part appeared in 1811, and which was finally completed, in 6 vol. 4to, in 1826. This great work was intended to comprise a complete survey of all the existing remains of ancient Etruria; and it has formed the great treasury of all subsequent writers on Etruscan antiquities and the Etruscan people. His other work was 'Lettere Lettere,' 4to, 1780, 1802-30; 'Galleria Omerica,' 3 vol. 4to, 1850-31, a work intended to illustrate the 'Idilii' and 'Odysseia' by the monuments of antiquity; 'Pitture di Vasi Fittili esibite dal Cav. F. Inghirami,' 4 vol. 4to, 1850-37, in which was his avowed object to illustrate the mythology and the history of the ancients; and 'Storia della Toscana, in Sette Epoca distribuita,' 16 vol. 8vo, 1841-43, the last two volumes being devoted to the bibliography and index. He also wrote several papers and a number of papers in the archives, and in the 'Archivo Storico Italiano,' &c. Cavalire Inghirami was for several years keeper of the Laurentine Library at Florence. He died on the 17th of May 1856.

INGLIS, SIR ROBERT HARRY, Bart., many years M.P. for the University of Oxford, was the only son of Sir Hugh Inglis, Bart., formerly chairman of the East India Company. He was born in 1786, and received his early education at Winchester, and Christchurch, Oxford. Soon after taking his degree, he became private secretary to the late Viscount Sidmouth, and was appointed by him one of the commissioners for settling the affairs of the Carnatic. In 1824 he entered parliament as member for Dundalk, a borough at that time in the possession of the Earl of Charleville. In 1826 he was elected for Ripon, the representation of which borough he resigned in the spring of 1829, in order to contest the University of Oxford against the late Sir Robert Peal, who had been re-elected. He was appointed Commissary-House in introducing the Roman Catholic Relief Bill. From that time he continued to represent the University until January 1855, when he retired from parliamentary life, and was sworn a member of the Privy Council. His public life was spent, for the most part, in appointments to which his appointment to the post of Lord Chief Justice he inherited the ancient opinions of Lords Sidmouth and Liverpool; he steadily opposed the Repeal of the Test and Corporation Acts, the Roman Catholic Relief and Reform Bills, and the admission of Jews into parliament, and every measure which he religiously thought would lead to unchristianise the legislature. On these points his opposition was strong and consistent, though to a certain extent characterised by partisanship and prejudice. He took an active part in the management of the religious societies of the Established Church, and also of the learned societies of the metropolis. In private life he was highly respected as an amiable and accomplished gentleman. He died in Bedford Square, London, May 5, 1855. He died intestate, and without an offence either at Common Law or by Statute, (4 & 5 Vict. c. 34.)

INJUNCTION, in Chancery. One of the recent improvements in the procedure of the Courts of Equity, consists in the abolition of the distinction between Common and Special Injunctions. An injunction is now a new route from the extremity of the realm of organic matter.

INJUNCTION, at Law. The Common Law Procedure Act, 1834, among other improvements, has enabled the Superior Courts of Common Law to grant writs of injunction after action brought, in order to restrain the repetition or continuance of the wrongful act complained of, thereby in this way avoiding the necessity of a resort to the Court of Chancery. This process is, it will be observed, of very limited application, an injunction being generally sought to prevent an injury, and not the perpetration of a wrong. See INJUNCTION, at Equity, and INJUNCTION, at Chancery.

INJUSTICE. [Chemistry, s. 3] INJUSTICE. (See INJUSTICE, s. 3.) INSOLVENCY. The Commissioners of the Court for the Relief of Insolvent Debtors no longer make circuits through England, to hear the petitions of prisoners confined for debt in the country districts. This branch of the jurisdiction of the Insolvency Court is now exercised by the County Court Judges, to whom the petition and schedule of the prisoner are referred for that purpose transmitted. The County Court Judge exercises the same authority as the Court in London, by desiring to know the reasons of the Insolvency. (10 & 11 Vict. c. 164.) See also PROCTIONS, Act, s. 3.

INTESTINES. The structure of the coats of the intestines has been most carefully observed by means of the microscope. The minute structure of the intestines corresponds to a considerable extent with that of the skin of the stomach. There are however differences of structure especially in the mucous coat of the intestines. We shall describe first the muscular structure, and in doing this we shall follow Professor Kolliker in his 'Manual of Human Physiology.' The muscular coat of the smaller intestines is somewhat thicker in the duodenum and the upper portions, than is the lower; it has in general a thickness of 2—4, and is composed of two coats, the internal and the external. The former are less developed, and do not form a continuous layer, since they are very few or entirely absent along the attachment of the mesentery; they are usually most distinct upon
the free border, though even here they may be readily torn away with the serous membrane, so as at once to leave the second layer exposed. The latter is complete and continuous, consisting of a thin layer of tissue which helps to connect the coats and is never不含一个有共同的核膜——0.003—0.005, with rounded or elongated nuclei, which lies immediately beneath the homogeneous external layer of the matrix, and is supplied by one or two small arteries of 0.01—0.015. The blood is usually carried back directly into the larger trunks of the submucous tissue by a vein of 0.022, which does not arise as in animals, by the arching round of the arterioles, but possibly from the gradual coalescence of the finest capillaries. The relation of the nuclei to the matrix, have not hitherto been perfectly made out; for although the majority of investigators are inclined, like the older observers, to suppose that they commence by one or two cecal branches, the number of muscular fibres, makes it very likely that they originate in a filiform manner. On this subject Professor Kölliker remarks that in the human subject he has never succeeded in meeting with villi distended with chyle, and in empty ones, he has been unable to obtain any decisive evidence; on the other hand, in animals, he feels certain that in many cases only a single lactule, which has a conical and frequently enlarged end, and whose diameter is much greater than that of the capillaries, traverses the axis of the villus. He says that he believes that all the narrow cylindrical and filiform villi will be found to present this condition, but that, on the other hand, the number and mode of origin of the lactules may possibly be different in the broad and foliaceous forms.

In addition, the organs the villi also contain, as Brücke discovered a short time ago, a thin layer of longitudinal smooth muscles, situated more centrally round the lactules; these however are not always distinct in man, they produce contractions of the villi, which are very evident immediately after death, and are frequently capable of being produced in the dead subject, and can only be observed in perfectly fresh portions of intestine. It consists everywhere of a simple layer of cylindrical cells slightly narrowed below of 0.01 — 0.012 in length and 0.04 in breadth, whose contents are usually lying but fine granules, and an oval, clear, vesicular nucleus, provided with one or two nucleoli. During life, these cells, which agree in all their chemical characters with the deeper cells of the oral epithelium, are so intimately united, that it is difficult to separate them, but on the contrary, are distinctly visible from without, and, under a magnifying glass, can be distinguished from those of the adjacent villi, so that they can be distinguished from those of the adjacent villi, so that they can be distinguished from those of the adjacent villi, so that they are at first either not at all or only indistinctly distinguishable, though on the surface they have the appearance of a beautiful mosaic. The cylindrical only become quite distinct when they are either spontaneously or artificially detached, and then show the passage in a longitudinal manner that they hang together in continuous portions, all the cells covering a villus sometimes coming off together like the calypters of a moss.

The addition of water to these cells produces a separation of the cell contents from the broad end, giving rise, in separate cells, to the appearance of a membrane thickened upon one side, and, in series of cells or entire villi, to that of a peculiar structureless coat, like the cuticle of plants; by its long action, however, or by that of the intestinal fluids, the bursting of the cells produces apertures in them, or they become distended into large pyriform clear vesicles. We may here refer to the changes which the epithelial cells and the villi in general undergo during digestion. The most striking circumstance is the small occurrence of fat-globules in different parts of the villi, which may always be observed during the formation of a fatty milk-white chyle. The succession of the morphological steps is as follows:—The fat appears first as a fine emulsion of the intestinal fluids, the cells in different regions of the villi, so that in each we soon observe a large ovoid shining droplet. The number of these fat-cells rapidly increases, and then the villi acquire a very peculiar appearance, often as if beset with pearls, and with parts of the villi so thickly studded with fat, and consequently bright and shining, with those which are empty and pale. In the end all the cells become filled with these droplets, and the epithelium appears quite dark by transmitted, but whitish by reflected light, giving its aspect to the whole villus.
With the repletion of the entire epithelial covering of the villae, absorption commences, but up to this time nothing has entered the lacteals. This however soon takes place, and the first indication we observe is the breaking up of the large drops of fat in the cells into many tolerably minute fatty molecules. When this has occurred, these drops penetrate the substance of the villus itself, fill it more and more, and at last enter the central lacteal, whose whole length they eventually occupy. In the mean while, fresh fat has been continually passing in from the intestinal canal, not in the form of large drops, but in the form of small ones, ever, but henceforward in small molecules or drops of the same kind as those which were at first developed secondarily in the cells. On the other hand, at a subsequent period, we not uncommonly meet in the interior of the villus with large rounded or oval masses of the nutritive element, especially in the immediate vicinity of the lacteals. In man the process is probably the same as in animals. These observations demonstrate that fatty matters are absorbed as such, and are not saponified; on the other hand, it cannot at present be certainly stated how it is that they penetrate the membrane of the epithelial cells, the permeability of the villus, and the walls of the lacteals.

The whole process may be compared to the imbition of a porous substance by the capillary vessels, much as by fat and fatty molecules of the chyme are probably absorbed simply in consequence of their being carried along with its fluid part. While digestion is going on, we frequently find the whole parenchyma of the villus densely filled with small nuclei, here and there surrounded by cells, which are never entirely absent in a villus, but are at other times far fewer, and particularly are not to be distinguished in its interior. Of the whole villi, small intestines contain two kinds of true glands: 1. tubular glands, which are disposed over the whole mucous membrane; 2. racemose glands, in the submucous tissue of the duodenum.

The Racemose Glands, or as they are commonly named, according to Brunner, are, at the commencement of the duodenum, upon the outer side of the mucous membrane, a continuous layer, which is best developed and thickest close to the pylorus, where it constitutes a considerable glandular mass, and extends about as far as the aperture of the biliary ducts. If the two layers of the muscular tissue be dissected off a stretched or distended duodenum, the glands may readily be recognised as yellowish flattened bodies of $\frac{1}{4} - \frac{1}{2}$ on the average $\frac{1}{4} - \frac{1}{2}$ with their angles rounded off, which incline within a little connective tissue, close to the mucous membrane, and send short excretory ducts into it. In their minute structure Brunner's glands, the terminal vesicles of which measure 0.080-0.090, even 0.089, agree perfectly with the racemose glands of the stomach in their component parts. The alkaline mucus, in which so formed elements are contained, having no digestive action upon coagulated protein compounds, and probably merely subservient to mechanical ends.

The Tubular, or Lieberkühnian Glands (cryptae mucosae), are distributed over the whole small intestines including the duodenum as innumerable straight narrow coeca, which occupy the entire thickness of the mucous membrane, and are frequently slightly enlarged by their extremities, though hardly ever dichotomously divided. The best idea of their number is obtained by viewing the mucous membrane either from above or in vertical section, under a low power. In the small intestines the coeca stand close together, almost like palisades; in the form of which we observe that the glands do not occupy the whole surface, but only the inter-space between the villi; here however they exist in such numbers as to leave no intervals of any width, the mucous surface between the villi appearing merely like a sheet.

Even on Peyer's patches, and over the solitary follicles, these glands are to be met with, but in man they lose those portions of the mucous membrane which lie immediately over the cores of these patches, and therefore are arranged like wings along the follicles.

The length of the Lieberkühnian glands equals the thickness of the mucous membrane and varies from $\frac{1}{4} - \frac{1}{2}$; their breadth is $0.095 - 0.096$, that of their aperture, $0.09 - 0.093$. The mucous membranes of the intestine contain two homologous membrana propria, and of a cylindrical epithelium, which even during chylification never, like that of the intestine, contains fat; their cavity is filled during life by a clear fluid secretion, the so-called intestinal juice, which however becomes rapidly changed after death, or on the addition of salt, so that the glands appear to be filled with cells, or with a granular mass.

The most important of the closed Follicles are Peyer's patches (glandulae aggregatae). They are rounded flattened organs, freely distributed in the submucous tissue of the duodenum, and may be found from the duodenum to the ileum, but they are not uncommonly to be met with in the lower part of the jejunal region, and even in the appendices epiploicae, and occasionally in the duodenum, and even in the inferior horizontal portion of the duodenum itself. Ordinarily there are 20 to 30 of them; but when they are found higher up there may be as many as 30 to 60; but they are always more closely united in the lowest portion of the ileum. The dimensions of the separate patches are in general the larger the closer they are to the cecum; their length is usually $\frac{1}{4} - \frac{1}{2}$, may diminish to $\frac{1}{4}$, and increase to $\frac{1}{4} - \frac{1}{2}$, or even 1'; their breadth is about $\frac{1}{4} - \frac{1}{2}$, may diminish to $\frac{1}{4}$, or even 0.09. In these patches the villi are very short, and the crypts of the villi are very deep. The epithelium of the villi is rather ciliation, and the base of the villi is thick. The young villi of the follicles of $\frac{1}{4} - \frac{1}{2}$ in diameter, either rounded or slightly conical towards the intestinal cavity, which lies partly in the mucous membrane itself, partly in the submucous tissue; and are of the one side not more than 0.09, or are distant from the mucous surface, while on the other they are in immediate contact with the muscular tunica, which is here somewhat more closely united with the mucous membrane.

Villi from the interior of the intestine their most striking feature in man is the presence of many small rounded depressions $\frac{1}{4} - \frac{1}{2}$, which corresponds with the separate follicles, and whose floor is indeed rendered slightly convex by the latter, but which present no villi whatever. The remainder of the patch is occupied by common villi, or by reticulated folds, and by the apertures of the Lieberkühnian glands; the latter are disposed around the slight elevations produced by the follicles in circles of 6 to 10 and more apertures, the corona tubulorum of authors.

The Solitary Follicles (glandulae solitariae) resemble the separate element of Peyer's patches so closely in size, content, and general structure, that there is no reason for considering them as distinct, particularly as the number of follicles per centimeter is the same as in the Peyer's patches. Animals at least, we find Peyer's patches with 2—3—5 follicles.

In man, as all writers justly agree, their number is exceedingly inconstant; sometimes not one can be found. In the small intestines of the whole species of animals, the origins of the ileo-colic valve, is thickly beset with them; or, lastly, they may occur in the ileum and jejunum, but in no very great number. Their entire absence must probably be considered abnormal, since they are covant in newly born children, being more abundant in the jejunum than in the ileum. The military vessels however, which are often met with in immense quantities in the small intestines and stomach in cutaneous affections of the alimentary tract, may be very probably or partially pathological, since the mucous membrane of the latter has been demonstrated in other organs also (in the liver according to Vorhow). The solitary follicles have the same structure as the elements of the patches, only they occur also in the mesenteric border, and support villi upon their intestinal surface, which is usually somewhat convex.

Professor Kölliker expresses himself as decidedly on the notion that the follicles of Peyer's patches have any aperture. Of their functions he says: They are the follicles of the intestine, in general: the closed glandular organs, analogous to the splenic follicles, the tonsils, and the lymphatic glands, which contain peculiar elements and a vascular network. In these a constant development of lymphatic follicles, which are elaborated from the plasma, supplied by the blood-vessels, and perhaps also from matters not of a fatty nature, absorbed from the intestine, a part of which in all probability is at
pieces in this manner was a portrait of Napoleon I. in the garden of Malmaison, the engraving from which, by Lingay, had a great run. This style was however soon abandoned by Isabey, who, having resolved to try whether, by carrying the principles of high art into miniature-painting, he could not elevate that branch of art in public estimation, executed in 1829 a piece of unusual size, containing a small figure, of "Le Reve de Premier Consul dans la cour des Tuileries." It caught the public taste, and established the painter's reputation, as the first in his line. From that time Napoleon and Isabey were the most frequent miniature-painters of the day. Whilst Napoleon I. was a plain officer of artillery, Isabey had been on terms of friendship with him, and when the empire was founded Isabey continued in favour, and was appointed miniature-painter in ordinary to the emperor. In this capacity he painted many of the miniature-portraits of Napoleon I., the empress, the young king of Rome his son, the members of the Bonaparte family, and the favourite courtiers and generals. Among the most famous of the imperial pictures was one on a large slab of porcelain, representing Napoleon I. and the most illustrious of his generals, and known as the 'Table des Maréchaux.' Besides the portraits, he executed several court and ceremonial pieces, one of which, a Visite de l'Empereur à la Manufacture de Porcelaine, is placed in the collection of the Oberkampf Government. He was so wisely entrusted with the direction of works relative to the coronation of the emperor, when he was named officer of the Legion of Honour.

On the first occasion of Napoleon I., Isabey accompanied the empress Marie Louise to Vienna, where he painted a large tablet of 'One of the Conferences at the Congress of Vienna,' chiefly remarkable for the faithful likenesses of the numerous important personages assembled. On Napoleon's return from Egypt, Isabey received a warning from the police, and prophesied the emperor by presenting him with a miniature of his son, which he had just painted at Vienna. The restoration of the Bourbons brought no loss of fortune to Isabey; but a picture which he exhibited at the Salon in 1817 of 'A child playing with Flowers,' caused some 'sensation' among the Parisians, from the child, who was holding up a bunch of forget-me-nots, bearing a striking resemblance to the young Napoleon. The 'Constitutionnel' having ventured to make a pointed allusion to the ill-luck received a warning from the police. Isabey soon after accepted an invitation to the court of St. Petersburg, where he painted the emperor Alexander, the empress, the grand-dukes Nicholas and Michael, and many of the magnates of the court. On his return to Paris he painted the portrait of Louis XVIII., and as long as he continued to paint found ample occupation; his sitters, it is said, having included most of the sovereigns, as well as a large proportion of the most distinguished personages, of Europe. Isabey lived till the last of the old age from the works he executed, as also by a good deal of mannerism.

ISARI, a genus of Cephal. belonging to the division Trypocopris, and the tribe Isarini of Léveillé. It is characterised by a compound, solid, capitalised, or elongated receptacle. The species are found parasitic upon caterpillars and the larvae of various insects. Robin enumerates the following species:

1. Isateratorum has been found upon the Carabidae in the autumn of the year.
2. I. floccosus, upon the larvae and chrysalides of Bombyx Jacobeus.
3. I. stirigosus, upon the chrysalides of Notus Upsilon.
4. I. arachnophilus, upon small spiders belonging to the genus Thoreutis.
5. I. lepra, upon the chrysalides of Notus inestabilis.
6. I. Tortaricus, observed by Robin upon an unknown spider, in the autumn.
7. I. crassus, upon decaying chrysalides.
8. I. ephebopus, upon a dead hornet.
9. I. exodeus, upon the larva of a moth.
10. I. Araneanum, an American species, found on spiders in Carolina.
11. I. Spinipalbus, also found in America, upon the caterpillars of the silk-worm moths.
12. I. giganteus, found upon a Mygale in the island of Cuba. (Robin, Histoire Naturelle des Versaphraes.)

ISMAIL, a strongly fortified town of Turkey, in the province of Silistria, is situated on the left bank of the northern or Kilis arm of the Danube, 90 miles east from the mouth of the Pruth, and about two miles that distance from the Black Sea, in 45° 21' N. lat., 28° 50' E. long., and has about 20,000 inhabitants. It was taken by storm by the Russians under Suwaroff, Dec. 28, 1797, when the Turkish garrison numbering 30,000 men were put to the sword; the Russians lost 20,000. Under the Turks Ismail was important, not only in a military but in a commercial point of view; it contained 17 mosques, a large number of khans and bazaars, and many splendid houses. On its capture by the Russians all was put to fire and sword, and the town remained in a ruined condition till 1812, when it was ceded to Russia by the treaty of Bucharest. Since then it has been rebuilt, and now contains about 2500 houses and 12 churches. The Kilis arm of the Danube is navigable for steamers and for vessels of considerable burden, of which about 150 enter the harbour of Ismail annually, and are chiefly engaged in the corn trade. There are remains of a fine Turkish palace in the town. Ismail is now chiefly of importance in a military point of view, and the Russians rendered its defences very strong. It was restored to Turkey after the late war in the Crimea, by the new adjustment of boundary consequent on the treaty of Paris of 1856.

ISONANDRA, a genus of Plants belonging to the natural order Sapotoaceae. It is distinguished by the stamens being all fertile, and twice as numerous as the lobes of the corolla.

1. Gutta (Hooker), the Gutta-Percha Tree, has its leaves on long stalks, when they unfold, a brown point golden beneath; flowers axillary, fasciil.; stamens 12. This tree is a native of the Malayan Archipelago.

The substance yielded by this tree, and designated by the name of Gutta-Percha (pronounced ' PERTA ') is, like Caoutchouc, a carburet of hydrogen, and isomeric with that substance, and possesses a great number of the properties which characterise India-Rubber (Cacoonroone), but exhibits certain special properties which admit of its being applied to particular uses to which caoutchouc is not adapted. Gutta-Percha possesses so great an indestructibility by means of chemical agents as caoutchouc. It has an intermediate consistence between that of leather and wood; it is capable of being softened by heat, and of regaining its primitive consistence on cooling. It is therefore at the same time capable of taking and of retaining the most delicate impressions. The important uses to which it has been lately applied are only the forerunners of those to which it will be adapted hereafter, provided a scarcity of this precious material (which unfortunately is produced in much less quantities than India-Rubber, and in localities much more circumscribed) does not present an obstacle to it.

Whilst the plants which furnish caoutchouc abound in the whole of the territori-al zone which extends between the tropics, the Isonandra Guttta is the only tree which yields Gutta-Percha. It grows scarcely anywhere except in certain parts of the Malayan Archipelago, and up to the present time it has been almost exclusively obtained from Singapore. It was brought for the first time into England in the days of Tradevant, as a curious product, under the name of Masser.

Wood; and subsequently it was frequently brought from China and other parts of the East, under the name of India-Rubber, in the form of elastic whips, sticks, &c. In 1843 Dr. D'Alemaud and W. Montgomery drew particular attention to it, together with its various singular properties, its easy manipulation, and the uses for which the Malay employed it. The most common employment of it was for whips; and it was by the introduction of a horse whip made of this substance, that its existence was for the first time known in Europe. The specimens of the products of the East Indies, shown in the Great Exhibition of 1851, proved that the natives of the country in which the X. Guttta grows know also how to appropriate it to the manufacture of different kinds of vases, and that European industry has little more to do than to imitate their processes.

The importation of Gutta-Percha into England, where the employment of this substance first drew attention, was in 1845 only 30,600 lbs.; but in 1848 it had increased to above 3,000,000 lbs.; and during the following years the importation has amounted to a much larger quantity, and one which begins to cause some apprehension as to the possibility of the supply sufficient for the requirements of the novel uses in store for it in the future. It is true that during its use Gutta-Percha is but little consumed, and the waste from the articles in this material, submitted to a proper softening, can be made to serve new uses; nevertheless its constantly increasing consumption, added to the barbarous manner in which the product has hitherto been extracted, may well justify some apprehension.

During the first few years of the employment of Gutta-Percha it was the custom to cut down the tree for the purpose of obtaining the juice, which, left to itself, very soon allowed the Gutta-Percha to separate and coagulate of its own accord. There is reason to hope that European industry will soon be embarked in the cultivation of this product, and that the Niaso (which is the native tree that gives to the tree which produces Gutta-Percha), multiplied by means of a regular culture, naturalised in other countries than those to which it is indigenous, and worked by regular incisions, which will only take from the tree a portion of its juice without hindering its development, will be the means of furnishing at a low price a substance which is destined to render notable services to industrial and domestic economy.

The Gutta-Percha which arrives in Europe in the form of lumps of some pounds weight is far from being pure. The natives of the Malayan Archipelago make no scruple of introducing into it stones, earth, &c.; the presence of which in the interior of these blocks renders a purification indispensable, which purification however is capable of being attained without much manipulation.

Indestructible by water, and at the same time a bad conductor of electricity, Gutta-Percha has been found available for conning the metallic wires employed in the electric telegraph; and the use of this substance may certainly claim its share in the success of the submarine telegraph, by means of which London and Paris and the other great cities of Europe are now brought within a few minutes of each other. It may be conceived to what a variety of forms a substance can be turned which, becoming soft without altering at the temperature of boiling water, regains at the ordinary temperature the slight elasticity and the consistence of leather.

JACK-TREE. [ASTRAGALUS.]

JACOB'S LADDER. [POLEMONIUM, S. 1.]

JAMAICANA. [CHEMISTRY, S. 2.]

JANIPHA, a genus of Plants belonging to the natural order Leguminosae. [Rhabdos, 3-angled, subulate; calyx white, 4 or 5-cleft, sweet-scented; the terminal leaflet is the longest. The Common Jasmine has been a favourite flower of human beings for ages, and the more so as the fruit of its fragrance extends far beyond the season of its blossoms and even after the fruit is ripe. The leaves are fragrant to the touch and the plant itself is a very useful one in that it is easily grown in a pot and can be kept over winter.

J. officinale, Common Jasmine, is a native of the South of Europe. It has opposite leaves, pinnate; leaflets ovate-acuminate; buds acute. The flowers are fragrant, white, and the branches angular. Calycine segments 5, subulate; corolla white, 4 or 5-cleft, sweet-scented; the terminal leaflet is the longest. The Common Jasmine has been a favourite flower of human beings for ages, and the more so as the fruit of its fragrance extends far beyond the season of its blossoms and even after the fruit is ripe. The leaves are fragrant to the touch and the plant itself is a very useful one in that it is easily grown in a pot and can be kept over winter.

J. grandiflorum has opposite pinnate leaves, leaflets blunted, the outer ones 3 to 5-cleft, buds horizontal. It is a native of the East Indies, and greatly resembles J. officinale, except in the size of the leaflets, and in the exterior ones being confluent, and the flowers larger and reddish underneath. Both this and the former species yield the true essential oil of jasmine of the shops.

J. wallichii is also thought to be electeric.

JATROPHA, a genus of Plants belonging to the natural order Euphorbiaceae. It has monocious flowers; a 5-parted or lobed calyx; corolla 5-parted or absent; stamens 8 or 10, with unequal anthers, epicalyx filamentous; styles 2, bident or dichotomous; fruit a capsule.

J. curcas, Physic- Nut, is a very common small tree, or bush, on the coast of Coromandel. The bark is smooth and light brown-coloured; leaves scattered, stalked, broad, coriaceous, 5-angled, smooth, about 6 inches long, with very large yellow flowers. The male flowers at the extremities of the ramifications on short articulated pedicels, and the female flowers in their axils. The fruits are large, hard, baccate, and a small one below each subdivision of the pinnate, and generally one pressing on the calyx; calyx 5-lobed; corolla 5-petalled, campanulate, somewhat hairy; disc of 5 glandular bodies round the base of the filaments; filaments, the central one very thick, columnar, the 5 exterior ones diliform towards the base, adhering to the central one, all erect, and a little longer than the calyx; anthers 10, sagitate, equal; stigma 5 supported by the large general filament, and 1 by each of the others. The leaves are rugulose and discous; warm and rimed with castor-oil, they are applied by the natives of India as poisons. The seeds are violently emetic and diuretic; their expressed oil is reckoned a good application in itch and scabies, and also a little diluted, in rhinorrhoea. The leaves of the green jatropha are considered useful in cases of asthma, and the juice of the seed is used in cases of healing; it dyes linen black. The oil, boiled with oxide of iron, forms a varnish used by the Chinese for covering boxes. In large doses the seeds are emetic poisons.

J. glauces is found in Arabia Felix. It has leaves from 3-5 lobed, mucronate serrate, toothed; petioles nacked; stipules palmate, with serrate branches, glandular at the apex. The seeds yield a stimulating oil recommended by the Hindoos as an external application in cases of rheumatic and paralytic aches.

J. glandulifera is a native of the East Indies. The leaves about the extremities of the branchlets are alternate, petiolated, and generally palmate; the lobes from 3 to 5, oblong, serate, with each serrature ending in a short green glandular-bearded bristles; stipulas briefly; many-cleft, each division ending in a glandular head; petals terminal, about as long as the leaves. Male flowers most numerous and terminal, small, of a pale yellowish-green colour. The female flowers few, and subterminal in the divisions of the panicle. The pale or greyish-coloured thin juice which exudes from a fresh wound is employed by the Hindoos as an escharotic to remove films from the eyes.

J. mucronata is a native of tropical America. It has palpably 11-lobed smooth leaves, the segments wedge-shaped and pinnatifid; stipules setaceous, multifid; flowers coriaceous, scarlet, with coloured pedicels. The seeds are one of the best of all emetics and purgatives, acting briskly, but without inconvenience; their effects are readily stayed by the administration of a glass of good white wine.
JAY REV. WILLIAM, was born on the 8th of May 1760 at Tisbury, Wilts. His father, who was the son of a small farmer, worked as a stone-cutter and mason, and young Jay first employed in these trades, before he was placed under the tuition of the Rev. Cornelius Winter of Marlborough Academy, an institution connected with the Congregational body, in which young men were trained for the ministry. His abilities soon became known and he was permitted to preach before the age of sixteen years. For about a year he officiated as the minister of Lady Maxwell’s Chapel at the Hotwells, Clifton; and on January 31st, 1791, he was settled as pastor of the church assembling in Argyle Chapel, Bath, a position which he maintained until the close of 1806, when he retired from the pastorate in January 1806, and died on the 27th of December in the same year, at the age of eighty-four. His reputation as a preacher was very high, and was by no means confined to his own denomination, that of the Independents. His published sermons have had very extensive circulation, and many a congregation throughout the kingdom has often listened to Jay’s sermons without knowing to whom they were primarily indebted for the instruction they were receiving. He was a pious and learned man, and his orations so useful also in the family, and so well adapted for reproduction in other pulpits, was their simplicity of style, combined with a clear and methodical statement of the lessons sought to be conveyed. The effect of his own ministrations was much enhanced by the art of memory, and by a full command of his excellent vocal powers. Mr. Jay’s regular congregation was large, and visitors to Bath usually repaired to his chapel to hear him preach. He generally made an annual visit to London and the seat, and in the metropolis and elsewhere he attracted crowded congregations. When he had completed fifty years of his ministerial labours his people held jubilee services, in connection with which, at a public breakfast in the Assembly Rooms on the 3rd of February 1812, and in the evening, the sermon was delivered and the address containing his orations were presented to Mr. Jay. Besides his sermons, of which several editions have been published, Mr. Jay wrote an Essay on Marriage; ‘Memoirs of the Rev. Cornelius Win- ter’; ‘Memoirs and the Rev. John Lectures on Female Scripture Characters’ (published since his death); and an Autobiography, from which and other sources a memoir of Mr. Jay was prepared by the Rev. Dr. Redford and the Rev. J. A. James, and published in 1854. A uniform edition of Mr. Jay’s works was published under the author’s superintendence in 1845-49 in twelve volumes, post-ovato.

JEFFREY, FRANCIS, was born in Edinburgh, on the 30th of November 1776, in the upper part of a house now numbered 17, Charles-street, George-square. His father, George Jeffrey, was one of the debtors of the University of Edinburgh, where he was for four years under the care of one of the under-masters, Mr. Luke Fraser—a worthy man, whose celebrity depends on his having, in three successive classes, three pupils no less famous than Walter Scott, Jeffrey, and Brougham. Jeffrey’s class-followed, while he was under Mr. Fraser, used afterwards to remember him as a little clever, anxious boy, always near the top of his class, and who never lost a place without shedding tears.” From Fraser’s class, he went to New College, where he was in 1795 to that of the rector, Dr. Adam, the author of the ‘Memoirs of the Reformation’ and noted alike for his scholarship and the simple integrity of his character. Jeffrey, as well as Scott, used afterwards to speak with the highest respect of this good old man. It was in the winter of 1796-78, while still attending Dr. Adam’s class, that Jeffrey, then a boy in his fourteenth year, saw the post Burns. He was walking along the High Street, when he was arrested by the appearance of a man on the pavement, whose air and manner, seemed to be from the country, but in whose dress otherwise it was something uncommon. It was Burns, then on his first visit to Edinburgh, and as the “little black fellow was gazing at him, some one standing at a shop-door near said to him “Ay, lad, your hat is very nice.” Jeffrey, as he looked at the Burns’ hat, never saw Burns again; but he used to dwell with pleasure on the incident.

In the winter of 1787, Jeffrey (his mother being then just dead) was sent to the University of Glasgow; his father for some reason or other preferring that university to the University of Edinburgh. Here he attended the Greek classes under Young, the logic class under Jardine (then recently appointed, but already with something of that reputation as a teacher which he was to add by improved and increased), and the moral philosophy class, then taught by a Professor TORY, and likely to regard the teaching of a Whig like Mair with suspicion. Jeffrey’s class-fellows at Glasgow remembered him afterwards as being there one of the cleverest of the younger students, somewhat, ‘petulant’ in his manner, and assiduous in his studies. Mair insisted on wearing on his upper lip in spirit of remonstrance and ridicule. It was in the debating societies of the college however that he first broke on his companions of that day in the full display of his superiority. He was even then a fluent and rapid speaker, a ready and ingenious writer, and a merciless critic of the essays and opinions of others. It was at this time also that he commenced the habit of serious and versetale reading, and of note-taking and essay-writing for the purpose of stores of information. He was assiduous after his removal from Glasgow back to Edinburgh in the year 1789. In his little room in his father’s house in the Lawmarket, he read and wrote, filling quires of manuscript with notes and abstracts from books, his mind always busy with some new project. Biog- phographer Lord Cockburn gives a list of 31 different manuscript essays on literary and metaphysical topics, all written by him between November 1789 and March 1790. About the same time, he had altered the Scots law and the civil law, and was at the University of Edinburgh. In 1791 he went to Queen’s College, Oxford, intending to complete his studies there. While at Oxford he was very solitary and melancholy; he disliked the place; and after nine months was overjoyed to receive a letter from his father, and his friend during his stay at Oxford, “I see nothing that is possible to acquire in this place.” On his return to Edin- burgh, in July, 1792, his friends found that his stay at Oxford had altered him in at least one thing: he no longer spoke in his former natural Scottish accent, but in a sharp and, as some thought it, an affected English style of pronunciation. “Jeffrey,” Lord Holland used afterwards to say, “had lost his broad Scotch at Oxford, but he had gained only the narrow English.” Very soon however his friends, who knew his real intellectual force and the genius of his heart, became reconciled to his new style of speech; and Lord Cockburn certifies that to his latest years Jeffrey had never really forgotten his native Doric, but could talk in the broad Scotch accent of his countrymen when he chose. He had a strong relish, too, for Scottish anecdotes and humour. For a while after his return from Oxford, it seemed uncertain whether he might not be called upon by the University to come a merchant; but the legal profession was at last definitely resolved on. In 1792-93 he again attended the law classes of Edinburgh University under Professors Hume and Wylie, as also the class of history under Alexander Tyler. Strange to say, he did not attend Dr.land Stewart—Stewart Wigham being an object in his father’s eyes. On the 12th of December 1792 he became a member of the famous Speculative Society, then at the height of its fame; and here he first formed the acquaintance of Scott and many other young men of the most promising and distinguished. The distinction to lawyers, literary men, and statesmen. For several years Jeffrey was one of the ornaments of this society, reading essays in his turn, and figuring with peculiar eclat in almost every debate. In short, it is said of Jeffrey, as well as of Horner and Brougham, that never in their most glorious days did they speak better than they did when young members of the Speculative. Already in their debates, Jeffrey, despite the Toryism of his father, had to show his Whig principles. While this was so, he continued his habits of various though desultory reading, and of incessant composition in private on all sorts of subjects. He had even a dream at this time that he was to be a great man, and that his father was to give him a great quantity of verse. Of this verse Lord Cockburn says, from inspection, that though “viewed as mere literary practice it is rather respectable,” “it could not have been accepted.
as poetry. He adds that in one constitutional quality of the poet, Jeffrey was certainly highly endowed—the love of 
extremes. When Whig, his part was the extreme Whig, his 16th of December, 1794, Jeffrey was called to the Scottish 
Bar. It was the time when Scotland was politically stagnant under the so-called Dundas reign; when the whole country was managed by corruption and patronage; when such a thing as the press or the press was unknown; when through the press was unknown?; when through four-fifths of the entire population a half who then constituted the population of Scotland was Tory, at the absolute bidding of Dundas; and when such few leading Whigs as there were in office were out of the way. On the whole, the Whig party however was increasing; and year after year year new lawyers of talent were attaching themselves to it. Among these young Whig lawyers, beating their heels idly in the Parliament House with no chance of briefs, and amusing themselves by social meetings at each other's lodgings and by essays and debates in the Speculative, Jeffrey was confessed among one of the chief, if not the chief. His prospects of practice were so small that for a time he had ample leisure for his literary essays. He began the 'Monthly Review' and other periodicals; and for a time contemplated the pursuit of literature professionally. In 1800-1 he attended Dugald Stewart's lectures on political economy. At last, in November 1801, his talents as a political writer were noticed, and he was invited, at a convivial meeting of Jeffrey, Sidney Smith, Horner, and Brougham, that the 'Edin-

burgh Review' was projected. Smith was the originator of the idea, but the others immediately concurred, and Constable, a man of the same interests and standing, joined the work. The first number of the new journal came out on the 10th of October, 1802; that number and two more were edited by Smith; but, on Smith's return to London, the entire management devolved on Jeffrey.

The great fact in Jeffrey's life, and that which makes his name memorable in the literary history of Britain, is that for a period of twenty-six years (1803-1829) he was the editor of, and one of the principal contributors to, the 'Edinburgh Review.' With the history of that journal, his career was identified, and he is inextricably linked to it. To use Jeffrey's own phrase, it stood on two legs—the one leg being the criticism of current literature; the other being Whig politics. Both as a literary critic and as a politician, Jeffrey was the leading Whig in Britain during his lifetime, and his articles in both capacities; to estimate the vast influence exerted by the 'Review' during his management, on the contemporary literature and contemporary politics of Britain; to revive the numerous controversies both literary and political, in which the 'Review' was engaged; or to reconsider the right and the wrong of its literary judgments, in particular, on the distinguished poets of the period, such as Scott, Byron, Southey, Cler poz, Wordsworth, &c., is here unnecessary. All this belongs to the well-known literary history of the first quarter of the present century. Suffice it to say, that Jeffrey's honesty in the expression of his opinions was never doubted; and that, where he was wrong, it was because his judgments, though honestly given, were limited by the essential nature of his own intellect. As a literary critic, he proceeded on what has been called "the beauty and blemish" principle of reviewing; that is, it was his regular habit first to state in clear, sharp, ornamental language what he considered the "beauties" of a poem or other work, and then to add a healthy influence on the mind, by his chastisements. And, although in following this method, he undoubtedly remained constitutionally insensible to the higher poetry of Wordsworth and his kindred consociates, he undoubtedly influenced a healthy influence on the minds by his chastisements. Where he praised, he praised heartily; and it is to his credit that, if his negative judgments have not been always ratified, his favourable decisions generally have. In politics there is now less question as to the value of his influence in promoting what was on the whole good and useful. He was uniformly on the side of progress and improvement; and, though he never was a Democrat, nor what would now be termed a Radical, but only a moderate Whig, it was in the spirit of that Moderate Whig, that is significant of the adaptation of his writings, both literary and political, to the purposes of rapid immediate effect, that, when a selection of his essays from the 'Edinburgh Review' was published in four volumes in 1845, the work did not meet with the same success as much of the literature of the former part of the century. So far as his literary merits are concerned, it has been accorded to the similar collections of the essays of Macaulay, Sidney Smith, Carlyle, and others.

To return to Jeffrey's life, apart from the 'Review,' his professional practice rapidly increased, as his powers as a lawyer were recognized by a number of his contemporaries. In such respects he was not without a rival at the Scottish bar—combining good knowledge of law with singular perspicuity and ingenuity, and a rapid, fluent, and brilliant style of eloquence.

As a speaker, he was regarded as a very able advocate. His most frequent practice was as a defendant in a libel case, where he was conducting the prosecution, after listening to his torrent of words, declared that, by calculation with his watch, "that man had actually spoken the English language twice over in three hours."

Jeffrey's triumphs as a piece of forensic art in criminal and civil cases, were numerous; but nowhere was he more successful, or more in his element, than at the bar of the General Assembly of the Scottish Church, at its annual meetings in Edinburgh, when he was generally involved in important cases. With his gradual increase of practice his wealth increased correspondingly, till at last he was in the receipt of a handsome annual income. But his wife did not live to share the full flush either of his fame or his fortune; she died at sea, during a voyage to Spain, in December, 1806, to distract his mind from this calamity, that the famous 'leaderless' duel between Jeffrey and Moore took place at Chalk Farm—occasioned by Jeffrey's notice of Moore's early poetry, and immortalized by Byron's reference to it in 'English Bards and Scotch Reviewers.' Jeffrey and Moore were all afterwards the best of friends; and both the duel and the satire were laughed over among them. With Scott also, notwithstanding that their original political conflict of interest, he became a friend of his. From the 'Edinburgh Review' to aid in founding the 'Quarterly' in 1809, Jeffrey always remained on terms of personal friendship; and nowhere were Scott's novels more cordially welcomed and praised than in the 'Edinburgh.' At length, after remaining a widower eight years, Moore and Jeffrey were all afterwards the best of friends; and both the duel and the satire were laughed over among them. With Scott also, notwithstanding that their original political conflict of interest, he became a friend of his. From the 'Edinburgh Review' to aid in founding the 'Quarterly' in 1809, Jeffrey always remained on terms of personal friendship; and nowhere were Scott's novels more cordially welcomed and praised than in the 'Edinburgh.'
through new phases of his life. In 1830 he was elected a member of the first parliament of William IV., being returned for Northumberland, and Douglas-Jerrod. In March 1831 he was unseated on petition, but was immediately returned again by Earl Fitzwilliam for the borough of Malton. He represented this borough till 1835, taking part in the Reform debates; and in the end of that year he was not returned. He was a member of the Reform Committee, and in 1836 he was a partner of Edinburgh, along with Mr. Abercromby, the speaker (now Lord Dunfermline). He remained in parliament till 1834, and was Lord Advocate of Scotland under the Grevy government. His parliamentary life was not an exciting one, the expectations that had been formed of his fame as a critic and a forensic orator; and he seems himself to have welcomed the change when, in 1834, he was raised to a vacant judgeship on the Scottish bench, and so relieved from the cares of parliamentary life. He retired to the Isle of Jersey, and henceforward was distinguished as Lord Jeffrey, though still legally only Francis Jeffrey, Esq. As a judge, he had a very high reputation for soundness, conscientiousness, and rapidity. He was noted for a habit of interrupting pleaders when they wandered, so as to bring them back to the point; and so long as he was in the second division more business was sent before him than before any other judge. He continued in the discharge of his duty almost to the last, dying on 6th November, 1850, at Craigie, on the 26th of January 1850. In the relations of private life, Lord Jeffrey was a singularly affectionate and amiable man, soft-hearted to a degree which surprised those who, till they knew him, had figured him only as a sharp and severe in the abstract. Lord Jeffrey's secret reserve is to be gathered from the selections from his correspondence published by his friend Lord Cockburn, as an appendix to his Biography, in 1852.

JERROLD, one of the geniuses of Mollusca belonging to the family Littorinidae, established by Mr. Alder, and named after Mr. Jeffreys of Swansea. The species were originally referred to Rissoa. Forbes and Hanley give two species, J. diaphana and J. opalina, as inhabiting British seas. In the N.T. 118, N. lat., 70° 36' E. long., in the valley of the Cabul River, on its right or southern bank, at a nearly equal distance from Cabul and Peshawar. Though the river begins to be navigated by rafts at this place, Jellalabad does not appear to be a commercial town. The ordinary population is between 2000 and 3000, but this is much increased in the winter season. The houses are low, and the streets narrow. The town was occupied by the British during the Afghan war, 1839-42. General Gough and Sir John Prendergast attempted its capture, but were repulsed by General Khan, who besieged the place with a large force in January 1842. At the conclusion of the war the British forces under General Pollock left Jellalabad in October 1842, first destroying its masts and the fortifications which had been erected for its defence.

JERROLD, DOUGLAS. With the higher order of minds every surrounding circumstance, especially of their earliest years, is education. The education of the child Douglas Jerrold was sometimes a laborious one of a father; the education of the boy was on the deck of a man-of-war; the education of the youth was in a printing-office. We can trace the fields of observation in which the dramatist, essayist, and journalist gathered his materials, and in which his habits of thought and study were formed. Douglas Jerrold was born in London, on the 3rd of January 1803. His father was manager of the Sheerness Theatre: the "many-coloured life" of the drama was thus familiar to him in his first years; and those who have known the boy, must have been conscious of an intense spirit in him to which faultless love will one day receive will understand the influence of this experience upon the pursuits of the man. But the boy was surrounded by grand and most attractive realities: the docks and arsenal of Sheerness—ships coming home to refit after tedious cruises—seamen who could talk of the Nile and Trafalgar. The lad, delicate, sensitive, was smitten with a passion for the life at sea; and, his wishes prevailing, a midshipman's appointment was obtained for him from Captain Beaufort, by brevet of Adm. Curtis, the novelist. At the end of the war he quitted the navy, not long after the first of August, having had to be chosen. He was apprenticed to a printer in London. The labours of a printer's apprentice are not ordinarily favourable to intellectual development; the duties of a compositor are not conducive to forcible mental and emotional development. But Douglas-Jerrod was so inattentive to the subject-matter of his employ that he rarely engage his thoughts. It was not in the printing-office that the mind of Douglas Jerrold was formed, although the aspirations of the boy might have thought that there was the sphere in which he might find a footing. The labours of a printer's apprentice were not the ones in which he aimed at popularity by false and dangerous doctrines upon the great principles of society and government. Its success,
compared with its previous position, is one of the many proofs that the largest numbers of readers are not to be pro-
 precipitated by what has been falsely considered as essential to
popularity—to write down to an iniquitous low intellectual
standard. Douglas Jerrold died June 8, 1867, at his residence,
Kilburn, near London. The amount derived from some per-
formances in honour of his memory was invested for his
widow and daughter. A pension of 100l. has also been
granted.

JERVIN. [Chemistry, S. 1.]

JET. [Coal, S. 2.]

JOHANNUT, TONY, was born at Offenbach, November 9,
1838. His father, Alfred, has been long known in
England as a designer of books. Tony, as his brother,
Tony commenced his professional career as an engraver. His
first painting was exhibited at the Exposition of 1851, 'On
Soliel' buvant à la porte d'une Hôtellerie.' Like his brother
he looked to English as well as French history and literature
for subjects for his pencil. Among his chief pictures are enu-
merated the 'Chanson de Dougs' (1838); 'La Siste' (1841);
'André et Valentine' (1844); 'Bataille de Fon-
tesey; now at Versailles; 'Petite Bracooniers' (1846); and
'Ecume de Plage' (1851). Though on the whole less suc-
cessful than his brother as a painter, when, like him, he
turned to designing for the wood-engraver, he proved at least
equitably happy; and as his life was more protracted, he
enjoyed a more material success. We have mentioned his
crucial. Among the more important of his book illus-
trations may be mentioned 'Werther,' the designs for which he
etched himself; Molière's works; 'Manon Lescaut,'
'Jérôme Patouret,' the Romances of George Sand; and
the 'Voyage d'Olivier,' of Galsworthy. His illustrations, though not un
erroneously exaggerated, and sometimes vetrica on caricature, are almost always cha-
acteristic, and full of knowledge and refinement, rendering
the books he illustrated among the very best examples of
their age. He died suddenly from an attack of apoplexy,
April 8, 1892.

JOHNSTON, JAMES F. W., late Professor of Chemistry
in the University of Durham. He was born at Paisley,
Ayrshire, July 24, 1842. After leaving the University of
Manchester, and afterwards returned again to Scotland,
residing at Kilmarnock. During this time the education of
young Johnston depended chiefly on his own efforts; he
was however so successful that he was enabled to obtain his own
livelihood by giving private instruction to pupils in the
University of Glasgow. In 1855 he removed to Durham,
where he opened a school. In 1850 he married the daughter of
Thomas Ridgely, Esq., of Park-end. By his marriage his circumstances were so much improved that he gave up his school work, desiring to devote himself entirely
long conceived of devoting himself to the study of chemistry.
He accordingly removed to Sweden, and became a pupil of
the celebrated Berzelius. He made so much progress in his
course of study that he was enabled to take the readership in
chemistry and mineralogy in his university. After his return to
Edinburgh, and resuming his occupation in Durham he
was invited to take the readership in chemistry and
mineralogy. This took place in 1853, whilst he was yet pursuing his
studies on the Continent, and the chair was not occupied till he returned to fill it. On his return, he took up his
residence at Edinburgh, and devoting himself to the depart-
ment of agricultural chemistry he became appointed chemist to
the Agricultural Society of Scotland. On the dissolution of
this society, he left Edinburgh, and resuming his occupation
in Durham. He now occupied himself principally with the
production of works on the relation of ch-mistry to agri-
culture. In this he was very successful, and few writers have
been more extensively read in this department of literature.
His 'Lecires on Agricultural Chemistry and Geology' are
an able exposition of the application of the principles of
chemical and geologcal science to the art of agriculture. He
did also publish a 'Catechism' on the same subject, which at
the time of his death, in 1855, had gone through thirty-
three editions. His writings were translated into almost every European
language. He had travelled in America, and was well
known as an agricultural chemist in the New World; and
his works have as large a circulation as in his own country. To the writers of the leading periodicals, such as the
work entitled 'Notes on North America,' in which he
"The unscientific reader. One of the most popular and
the last of his works was his 'Chemistry of Common Life,'
which has had a vast circulation, and done much for diffusing
his knowledge. The principles of chemistry involved in the
ordinary occupations of human life are at present more
readily shown to be without foundation. This work origi-
nally appeared as a series of magazine articles. Professor
Johnston contributed to the 'Edinburgh Review' and other
journals. He has also published many papers in the Tran-
sactions and other scientific journals. In the autumn of
summer of 1853 he was travelling on the Continent in his usual
health, when he was suddenly seized with spitting of blood,
which terminated in a rapid decline, and he died at Durham
on the 18th of September of that year. He was made a Fel-
low of the Royal Society in 1837, and was a member of
other learned societies.

JOINT-STOCK COMPANIES. The great alteration in
the principles which have influenced modern legislation with
reference to Joint-Stock Companies calls for some repetition
of what has been already stated with reference to them.

[Bank, Banker, Banking; Partnership.]

These Companies are distinguished from other Corporations
by the facility with which they can be formed, not for any public or administrative
purpose merely, but for carrying on a business with a view to
individual profit. They possess other peculiari
equally deserving of notice.

This system of association, which has received such
admirable development since [1850], is in England, in
recent origin. Institutions founded on the same principle
as the trading guilds of the middle ages seem to have existed
among the Saxons; and soon after the conquest we find
companies of different trades established in the various sea-
ports and other towns of the kingdom. The trading
fraternities generally became in course of time chartered
companies, each possessing the exclusive privilege of
pursuing the particular occupation which it professed to
perform. The institution of these companies was followed
in the municipal corporations, the franchises of which
could in many cases be enjoyed by those only who were
free of one of the companies into which the community was
divided. In this position they remained until the Municipal
Corporation Reform Act.

Besides these guilds, or companies, other trading associations sprung up from time to time. The
genereal company of Germans, called also the Merchants of
the Hanse, dates from 1290, and became in the fifteenth cen-
tury the Company of the Merchant Adventurers of England, as the hankiers.

In the seventeenth century, the speculative mania,
remembered in connection with the famous South Sea Com-
pa.ny; of which we have seen counterparts more than once
since the middle of the nineteenth century, was occasioned by
this novel development of the associative tendency, the
'bubble Act' (6 Geo. I. c. 18), was passed, declaring all companies
which presumed to act as corporate bodies, and to pretend
to raise transferable stock, public nuisances, and the pro-
cumbly and stability of the country. Its provisions were
directed not so much against the offence of acting as a cor-
poration without authority, as with a view to prevent the
frauds of unprincipled adventurers, who prop-ed schemes
merely as a pretext to extract money out of the pockets of
the thoughtless. Such an object, however, is not to be effected
by mere legislation. The gambling in stocks and shares which seems to be periodically revived among us, and which, in 1719, produced the 'Buble Act,' came to an end during the crash following the wild speculation which led to the statute; but the Act, nevertheless, had some effect in realising outstanding projects of incorporation and therein was to those against which its provisions were directed.

During the last century a large number of useful public undertakings, such as the making of canals, bridges, harbours, docks, and the like, have been carried into effect by companies incorporated under Acts of Parliament, and in particular by Acts of Parliament; and more recently our gigantic system of intercommunication by railway has been obtained in a similar way. In these undertakings, the assistance of funds, where necessary, was no doubt given to enable the company to carry out its project by the compulsory purchase of property, and to make by-laws binding on the public for the protective rights of the corporation. These companies, like the old trading associations, partake of the advantages derived from incorporation; advantages in which mere associations of individuals joined together to promote such common objects cannot possibly participate. A mere assemblage of adventurers cannot, for instance, by any agreement among them-eves, sue or be sued in the name of any one of their body, or of any officer they may select for the purpose; they are liable, on the contrary, to the same laws as ordinary partnerships, and each individual is personally answerable for his share of the debts, and accountable for the contracts and debts, of the body generally. To facilitate the operations of such associations, various statutes have been passed; but owing to the fluctuation in opinion regarding the true policy, the legislation relating to them has not been altogether consistent.

The original mode of forming a joint-stock company was by means of a deed of settlement, which constituted trustees of the partnership property, directors of its affairs, auditors of its accounts, and other officers, defined the number of shares into which the capital was divided, and the form and mode of transferring them, and laid down rules for periodical meetings of the shareholders. In the absence of legislative definition, the rights and liabilities of the members of such bodies, in relation to the public, were the same as those of other members of ordinary partnerships; their rights and liabilities inter se depended on the provisions of the deed of settlement. The difficulties which were soon found to arise, in carrying on the business of such undertakings, induced the earlier joint-stock companies to obtain private Acts of Parliament, which usually enabled the company to sue and be sued in the name of the Secretary or some public officer appointed for the purpose, and almost invariably concluded that no person should be entitled to incorporate the partnership; for one effect of incorporation would have been to destroy the individual responsibility of the members for the acts of the association, which the Legislature deemed recently insufficient.

As joint-stock companies, however, increased in number and in usefulness, the cost and trouble necessary to obtain a private Act of Parliament were felt to be extremely burdensome; and the attention of Parliament being called to the subject, it was thought expedient by the Legislature to empower the Crown to grant to joint-stock companies such powers as were likely to be most useful to them, without, however, conferring all the incidents of a corporation. The first attempt at legislation in this direction was the Statute 3 4 Will. c. 91, which enabled the Crown, in a charter of incorporation thereunder to be granted, to provide that the members should be individually liable for the debts and engagements of the corporation. This Act proving inoperative, another mode of proceeding was tried by 4 & 5 Will. c. 94, which enabled the Crown to grant to joint-stock companies the privilege of suing and being sued in the name of any of their officers. This Act was soon repealed, and another attempt made in the direction by 7 Will. I. c. 95, and 1 Vict. c. 73. At length the 7 & 8 Vict. c. 49, for the registration, incorporation, and regulation of all future joint-stock companies not requiring nor obtaining a charter or Act of Parliament. This statute introduced a system of public limitation, whereby the company was limited to what was called a nominal capital, for the purpose of carrying on the business for which it was formed, according to the provisions of its deed of settlement; but every shareholder remained liable individually for the debts and contracts of the company, and might be proceeded against as though he were not a member of the corporation. Banking companies were excepted from this statute, the 7 & 8 Vict. c. 113 being passed for their special regulation.

A great many joint-stock companies were formed and by regulations obtained the corporate privileges which they were now enabled to do; but before long the affairs of several became involved; and the difficulties which then presented themselves in attempting to adjust the rights and liabilities of the parties had so much impressed the shareholders led to the repeal of the Registration and Winding-up Acts, c. 11, & 12 Vict. c. 45, and 12 & 13 Vict. c. 108, which for several years exercised the acumen of the Judges of the Court of Chancery, in a series of hopeless attempts to interpret and follow out their provisions. The effect of the food of the companies was unmistakable, and the public declared, a very strong light upon the principles of legislation applicable to joint-stock companies; and the knowledge was purchased at an enormous expense, which has recently led to the repeal of the Registration and Winding-up Acts, and to a total remoulding of the law regarding these associations. This has been effected by the statute 19 & 20 Vict. c. 47, which provides for the registration, under the provisions of these Acts, of all companies previously registered under the former statute. The Act itself has been amended by 20 & 21 Vict. c. 14.

The principle of limited liability, or the restriction of the responsibility of each member to the amount of the capital subscribed by him, which had long been conceded to partnerships, was declared in the statute. This statute containing the main principles the effects to the commonwealth, has been at length extended to all joint-stock companies coming within the operation of these Acts, which choose to adopt their provisions, on the simple condition of obtaining registration and conforming to the few simple rules, whereby the personality of the company is defined. From its operation are excepted all companies established by Act of Parliament, royal charter, or letters patent, all banking or insurance companies, and associations engaged in mining in the Standing committees, where companies with a limited liability may be formed conformably to certain local customs, which are generally known as the "Cost-Book System." There now exist, therefore, four classes of joint-stock companies:

1. Trading companies incorporated by special Acts of Parliament. This class includes railway, dock, harbour, and canal companies, many insurance companies, and a vast number of other bodies engaged in every species of profitable employment. Formerly each such company Act incorporated was governed by the peculiar provisions of the Act which it obtained; but in order to introduce uniformity, a general Act, applying to all future companies, was passed under the title of "The Companies' Clauses Consolidation Act," 8 & 9 Vict. c. 16. This statute contains the regulations of the proceedings, the transfer of the shares, and the general management of companies incorporated by Act of Parliament. 'The Lands' Clauses Consolidation Act,' 1845, was at the same time, consolidating all those provisions which it had previously been necessary to include in the special Act of any company, which required powers of acquiring land compulsorily for the purposes of the undertaking.

The peculiar character of railway undertakings rendered necessary 'The Railways' Clauses Consolidation Act,' 1845; which lays down regulations as to the construction of railway works, the amount and mode of enforcing the payment of tolls and fares, and the making of by-laws for the conduct of the business, which are binding upon all persons whatsoever.

2. A second class of joint-stock companies are the very few established under the statute 1 Vict. c. 73, or the preceding Act, 6 Geo. IV. c. 91, which have been already referred to.

3. Banking companies formed since 1844 form a distinct class. They were until recently governed by the statute 7 & 8 Vict. c. 113, but must now be registered under the "Act for the prevention of the corporate frauds mentioned in the statute, the individual liability of the partners, and contains provisions for the company being wound up. Banking companies constituted previous to 1844, may avail themselves of the advantages of the statute, by being registered under its provisions.

4. The last class of trading corporations are the registered joint-stock companies, regulated by the "Joint-Stock Companies' Acts," 1856 and 1867, under which seven or more
persons may, by subscribing a memorandum of association, and otherwise complying with the requirements of the statute in respect of registration, form themselves into an incorporated company, with or without limited liability.

This registration is obtained by delivering to the registrar of joint-stock companies a memorandum of association, stating certain particulars in a prescribed form. Upon registration being effected, the subscribers, together with such persons as from time to time may be admitted to the shareholding, become the shareholders of the company, and thereby acquire the rights of a body corporate, hereby forming a body corporate, having a perpetual succession and a common seal, and power to hold lands to a certain extent, and with consent of the Board of Trade to any extent whatever.

Every member shall hold himself forth as one of those who are members liable either with or without limit, according to the wishes of any member who may adopt the principle of limited liability or not. Where the liability of the shareholders is limited by the memorandum of association, the word ‘limited’ must be the first in the registered title of the company, and must be inseparably attached to its name.

The statute requires that a register of shareholders shall be kept; and that this list be annually revised, and a copy furnished to the registrar of joint-stock companies. This copy is open to public inspection, so that all the particulars of importance respecting the company can be at any time ascertained by persons dealing with it.

The affairs of a registered company are also liable to examination by the Board of Trade, and the statutes contain a complete code of regulations for winding up a company unable to meet its engagements, or which it is thought desirable to wind up for other reasons. Directors, who do not obtain success by profit or the satisfaction of the subscribers, are likely to be severally and severally liable to the extent of the dividends, for all the debts of the company; and every person personifying or carrying on the business of the company when the number of the partners is less than seven, is severally liable for its debts.

This species of corporation may be dissolved by being wound up, either voluntarily or compulsorily. A voluntary winding up may take place: 1. Whenever the period, if any, fixed for the duration of the company expires, or the event to which that period is referred; or 2. Whenever the company has passed a special resolution requiring its winding up. A company may be wound up compulsorily: 1. By virtue of a special resolution to that effect; 2. Whenever it does not commence business within a year of its incorporation, or suspends business for a year; 3. Whenever the shareholders are less than seven in number; 4. Whenever the company is unable to pay its debts; or, 5. Whenever the amounts of the капитал have been lost or become unavaileble.

A company is to be deemed unable to pay its debts: 1. Whenever a creditor for 50l. has served a demand of payment, and the company has for three months elected to pay the amount owing, or to secure or compound for it, without the satisfaction of the creditor; and, 2. Whenever an execution is returned unsatisfied, in whole or in part.

The proceedings take place in the case of companies whose liability is limited in the Court of Chancery; in the case of companies with limited liability in the Court of Bankruptcy. (Blackstone’s Commentaries, Mr. Kerr’s edition, vol. i. p. 526.)

JUDSON, ADONIRAM, founder of the American Baptist Mission in Birma, was born August 9, 1788, at Malden, Massachusetts, where his father was a Congregationalist minister. Having passed through the classes of Brown University, where he took honour, he entered the divinity department of the Seminary; and whilst there, a student by Dr. Claudius Buchanan, which he was called to meet with, turned his thoughts towards the missionary service in India. Some fellow-students, to whom he communicated his views, became similarly impressed, and they even went before the college authorities their desire to devote themselves to the missionary office. There was then no missionary society in America, but the council referred the matter to a general committee, who resolved it was advisable to institute a ‘Board of Commissioners for Foreign Missions.’ Whilst this board was in process of organisation, young Judson proceeded in 1811 to England, to consult with the directors of the London Missionary Society. On his way the vessel in which he sailed was wrecked, and carried into Bayonne, but Judson was released, after a short detention, at the intercession of some of his countrymen. In London, he received only qualified promises of aid, but the American Board of Commissioners, re-
where they met with a warm welcome from Dr. Carey and the Scaramore missionaries, but the Benga government, resuming their authority, abruptly ordered Judson and his companions to return to America by the same ship in which they had arrived. Judson however was not disposed to give up his purpose so easily. He accordingly took a passage to the Isle of France, proceeded there from to Bombay, and thence (via Ceylon) to England, where he arrived July 14, 1813.

Before leaving Calcutta, Mr. Judson, whose views on the subject of baptism had undergone a change, was, with his wife, re-baptized by immersion. He was rejoiced at the change, he said, and in consequence resigned his connection with the Board of Missions; and when he landed at Rangoon to commence his missionary work he was unconnected with any society, and without any means of future support. He addressed himself however with great success to the acquisition of the Burmese language unaided by dictionary or grammar, whilst the native he engaged as a teacher knew not a word of English. By persevering labour he in some two or three years was able to speak the language with some degree of readiness. The Baptists of America, on hearing of his devotion, had promptly formed a missionary society to support him, and sent him out some assistents, one of whom was a printer. The Scaramore missionaries presented a printing-press and a font of Burmese type, made for them out of pewter, and personally instructing the natives, but desiring to benefit those whom his voice could not reach, drew up in Burmese a 'Summary of Christian Doctrine,' which was the first work issued from the Rangoon press; and portions of scripture and sermons were also prepared. As a native work Mr. Judson made visits to other Burmese towns, and to Ava, where he had an interview with the king; and, having obtained permission set about establishing schools, in which he had also mastered the language, was a very earnest and successful helper. The mission was going on favourably, when the sovereign of Birma provoked the English to declare war. Rangoon was made a point of attack by the British forces; but before they arrived, the other towns, was seized and put into prison. There he remained for several months, subjected the greater part of the time to the most cruel treatment; but at length, when the success of the English was beyond question, he was employed to act as translator for the Birman government, and Mrs. Judson was sent to the British camp to mediate. A treaty of peace being signed, Mr. Judson and his companions were permitted to resume their labours. He returned to Rangoon; and there, worn out with toil and anxiety, the companion of his early dangers and the sharer of his labours died, October 28, 1826, during his absence in Ava. Some eight years later he married a second wife, the widow of a fellow-missionary named Boardman.

From an early period Mr. Judson had regarded the translation of the Bible into the Burmese tongue as one of the most important duties of a missionary's life; and, after having been for several years engaged upon it, he at length, January 31st, 1834, had the happiness to complete his task. He lost no time in putting it to press, and by the 6th of April, 1834, it was finished. The first volume, in 8 vols., was published. But he soon became convinced of its many imperfections, and he at once set about thoroughly revising the whole, with such assistance as he could obtain. This revision was completed in the autumn of 1840, and immediately printed in a thick 4to volume. It has since undergone careful correction by various Oriental scholars, and now holds a high place among the translations of the Scriptures into the eastern tongues. It is almost as soon as this printing of this revision was finished, the Bible was published, with characteristic energy Mr. Judson commenced at Moulinez, and under his brother-in-law. He then removed, the preparation of a Burmese Dictionary. But his ill-health interrupted the work, and the health of his wife failing also, he determined to return to Am-rica, in the hope that their native air might restore their vigour. Mrs. Judson died off St. Helena (September 1st, 1840), but he arrived in safety at Boston a month afterwards. His reception by the various religious societies in America was of the most cordial kind. Special services were every-where held in his honour, and wherever he went, was met and greeted him. His stay however was but brief, he had determined to return, and if possible, end his days in Birma. But he did not return alone. Anxious to find some one qualified to take the place of his wife, he sent to England (the first he had already written), he was introduced to an accomplished young lady, Miss Chubbuck, whose writings under the pseudonym of Fanny Forester, had had an un-usually large amount of popularity in religious circles; and he not only undertook to write the life of the deceased Mrs. Judson, but soon consented to become the third. They were married in June 1846; in July they embarked at Boston, and in December they landed at Moulinez. The mission was now in a flourishing state, and Judson felt that he might now devote himself to the completion of his Dictionary. Of this he was permitted to see the first part printed in 1849, but he did not live to complete it. His health failed, and he was directed to proceed to England, in March 1851. He embarked, but the Ganges rapidly worse, and died at sea on the 12th of April 1852. His 'Burmese and English Dictionary' was completed from his papers by Mr. E. A. Stevens, and printed at Moulinez in 1852. It is regarded as a work of great value, and in fact the first of its kind written in the Burmese language, and is a valuable contribution to the study of that language and of the history of India.

Several Lives of Mr. Judson have been published, of which the list of the most important may be given for the present:

J. R. Wylie, 'Memoirs of Mrs. Judson,' 1856; Fanny Forester, 'The Records of Alderbrook,' a work very popular in America, and once reprinted in England; and Mrs. Judson's own work, 'Secret.' 'Missionary Biography;' 'The Kathayan Siva;' &c. She died June 1, 1854.

JUGLANS. [WALNUT-TREE.]

JULIUS, a genius of Fishes belonging to the family Chondrostei, and the order Acipenseridae. It is a smallish and gill-cover without scales, the lateral line bent suddenly downwards when opposite the end of the dorsal fins. In other respects this genus resembles Labrus. [Labrini.] An example of a very beautiful species of this genus, known under the name of the Rainbow-Wrasse, was described by Donovan as taken off the coast of Cornwall. It is the J. Mediterraneus of Risso, the J. vulgaris of Fleming and Cuvier. This fish is most remarkable for its varied colours. Its back is greenish-blue; the longitudinal band is orange; beneath it are yellowish-coloured bands on a silvery ground; the head is variegated with brown, yellow, blue, and silver; the dorsal fin orange, with a purple spot on the membrane connecting the three spinous rays. [Yarrell, British Fishes.]

JUNIPERUS, a genus of plants belonging to the natural order Junaceae. This genus is distinguished by its inferior perianth, composed of 6 glumaceous leaves; its 3-celled 3-valved capsules, the seed-bearing dispersions of the valves being in their mature state; the seeds are found mostly in moist boggy situations in the colder parts of the world. Several species are of great importance to the horticulturist.

J. effusus, the Soft Rush, and J. communis, the Common Rush, are used in making of the country for placing into mats, for chair-bottoms, and for constructing small lady-baskets. The wicks also of the candles known as rush-candles are made from the pith, or more properly speaking the softer inner portion of the stem of the same species which is used as tinder. The rush-cane is cultivated in Japan like rice entirely for making floor-casts.

Rushes of various kinds form frequently very troublesome weeds in agriculture. They grow best on rich land that is wet and cold. The stems are often planted during the winter over with dry materials of various kinds, as ashes, lime, and drift from roads; but the best mode of getting rid of them is to fork them up by the roots in the summer, and after let them lie for a fortnight or three weeks to dry them there, and then plant them in the field. Whether they be a proper mode of getting rid of them unless the ground on which they grow is well drained.

JUNGMANN, JOSEF, an eminent Bohemian lexicog- rapher, was born at Hudditsch, February 28th, 1671, on the 16th of July 1772. His father was a peasant, who especially occupied himself with the management of bees, and Jungmann, who early showed a literary turn, had much to
struggle with in devoting himself to his favourite pursuits. His example appears to have produced an effect on others of the family, for Antonin, a younger brother, became a physician, and was admitted into the schools of Bohemia in 1774, and Jungmann, though from his name he was evidently of German descent, and though, as his after life evinced, he had talents for acquiring languages, seems to have felt as a peculiar hardship the difficulty of obtaining a knowledge of his native tongue. He made it the main business of his after life to restore and promote the study and cultivation of the Bohemian language, which, in his boyhood, was almost abandoned to the use of the peasantry, a habit which persisted in his exhortations, is now the ordinary language of Bohemian authors, who were formerly accustomed to employ either German or Latin. He studied first at Beranu, and then at the University of Prague; and in the year 1799 obtained an appointment in the University, a quality may ascribe to a grammar school of Leitmeritz, where he devoted part of his leisure to giving gratuitous instruction in Bohemian. While at Leitmeritz he translated several specimens of English poetry, "Rope's *Elisa*," and "Messiah," Goldsmith's "Edwin and Angelina;" Gray's "Elegy in a Country Church-yard;" and above all the "Paradise Lost," which was completed about 1804, but not published till 1811, and which came to a second edition in 1843, in the "Novoexcâla Bibliotheca," published at Vienne, was transferred to Prague as professor of Latin at the grammar school of the Old-Town, of which, in 1834, he became the prefect, or principal. In 1840 he was chosen rector of the university, an office which was conferred on him by the mayor of the city the year before, while his brother Jan read high mass as part of the ceremonies. Antonin, who has written several medical works in Bohemian, has also published an essay on the Sanscrit language, and Jan is likewise an author in the native tongue. In 1837 the labours of his compatriot Joseph von Schiller from the management of the gymnasium, but he was still occupied with correcting works for the press at the time of his death, on the 16th of November 1847. He had for several years been an assistant professor at the University, and was buried in the cemetery of Strahov.

Jungmann is the author of two works which are certain to preserve his name. One, the "Slovinic Cesko-Nemecky," the great Bohemian Dictionary, in five quarto volumes, containing at least four thousand pages of close print in double columns, is a stupendous monument of zeal and diligence, which the Bohemians proudly place by the side of Johnson and Adelung. The only other dictionary of a Slavonic language which can be compared to it is the Polish of Linde, which appeared in 1836, and was only an uncorrected reprint of the first edition of 1821. In conformity with its title, "Bohemian-German Dictionary," equivalent to the Bohemian words are given in German in this elaborate work, but the main mass of information which it contains is in Bohemian. The dictionary, even the Preface is given solely in Bohemian. This dictionary, which passed through the press between 1835 and 1839, was published at the expense of the Bohemian Museum, and in an imperial decree which was issued soon after its appearance, it was directed that the orthography adopted by Jungmann should be taken as a standard in the schools of the country. The triumph however was a short-lived one, for already in 1842 the Museum had adopted another system of orthography, to which Jungmann was obliged to conform in a later edition issued under its auspices, hoping, as he tells us in his "History of Bohemian Literature," that this new system might be the last. This "History" is his other great labour, and it is a most useful compendium of all who take interest in a curious branch of literary research. The first edition, which was issued in 1825, was out of print for several years before the appearance of the second, which Jungmann was engaged upon at the time of his death, and which was published in 1840. It is as much a model as his dictionary, the result of a complete Bohemian bibliography. The narrative portion, which is somewhat dry, hardly occupies a tenth part of the work, the remainder is a complete and minute enumeration of every book in the Bohemian language, with all its various titles and multiple editions and translations. Every author who could acquire information, from those of the earliest period, the manuscripts discovered by Hanka, to the year 1846. He even had the patience to form a list of the separate articles in periodicals, so that, with the assistance of every article, which of the works of Dickens, Scott, and Shakspere were translated into Bohemian by the year 1846, who were the translators, and when the versions appeared. The miscellaneous writings of Jungmann were collected in one volume, and published by the Bohemian Museum. They mainly consist of translations from English, French, and German, but there are some essays on the favourite subject of his native language, which are curious in matters and animated in the spirit of patriotism. JUROT ANDOCHE, DUC D'ABRANTES, was born at Bussy-les-Forges, on the 24th of September 1771, according to the Duchess's "Memoirs," whilst all the biographical dictionaries fix the date in October of the same year. He had been destined to the law, but the political events of 1791 induced him to enlist in the company of volunteers raised in the department of the Côte-d'Or; he soon distinguished himself, and his fellow-soldiers made him a sergeant on the field for one of his acts of daring. In that grade he was serving in the reign of Louis XVI, when Bonaparte, not yet a general, commanded the artillery, and having discerned the soldierly qualities of Junot, attached him to his person. The capture of the place raised the commandant to a general of brigade, when Junot was made a captain, and became the first aide-de-camp to General Bonaparte. For nearly two years he continued the sole aide-de-camp of General Bonaparte; he is even said to have shared his purse with his superior officer during the few months that he remained unattached to the 13th Vässelin in 1795.

He accompanied Bonaparte to Italy, in 1796, and was present at Lodi, Arcola, Castiglione, and Lonato, at which last battle he was badly wounded. In 1799, he took part in the campaign in Egypt, when at the combat of Nasare, with a troop of the guard, on horseback, he killed a thousand Mussulmans in check, till Kleber came to his relief. He greatly assisted Bonaparte on the 18th Brumaire, in overthrowing the Directory. For this timely service he was made Commander of Paris, in 1804, and carried the crown of the little Nicole de Dern argued (whose family had long been connected with that of Bonaparte) on the 18th October of the same year; and created a general of division in 1801. In 1804 he was appointed Governor of Paris. On the 1st of February, 1806, Bonaparte gave the title of Marshal to D'Abont, besides being decorated with the grand eagle of the Legion of Honour. He was likewise sent on several missions to the Court of Lisbon, his part of ambassador being suddenly changed at last into that of aggressor, when the good understanding between France and Portugal had ceased, in 1806. Junot then took possession of Portugal, and held his ground there for nearly two years, when Sir Arthur Wellesley's victory at Vimeiros, on the 1st of August 1808, and the conclusion of a treaty of peace by the peace of Tilsit, the battle, was followed by the evacuation of Portugal by the French army, and Junot's return to Paris. He had already received his title as Duc d'Abrantes; but from this period his star was lost. In 1812 he was made one of the regimented, and was estranged from his orders. In 1813 he was directed to join the grand armée, and the 8th corps was ostensibly placed under his command, but the orders from Berthier were transmitted rather to his lieutenants than to himself, and the only time his name was mentioned in a bulletin, he was reflected upon as having shown "a want of resolution." Under this reproach his spirit sank; he was refused employment in the campaign of 1813, and shortly afterwards was attacked with mental disease. In this state he was conveyed to the houses of his father, at Montpelier, on the 22nd of July 1813; the following day he threw himself out of a window, broke one of his thighs, and it became necessary to amputate the leg. He died on the 25th.

Lauride Paix, Duchess d'Abonts, was born at Montpelier, November 6, 1754, and was only sixteen when married to Junot, in 1800. She was a woman of great frankness of speech, and equally remarkable for the prodigality of her expenditure. As a consequence she was frequently obliged during her husband's life, and when his death and the fall of Napoleon had turned the tide of her fortune, she had no savings to support herself and family. She therefore had recourse to her pen for her subsistence. She wrote many patriotic and historical works under the title of "Souvenirs historiques sur Napoleon," published in 1831. As these memoirs contained many incidents relating to the early life of the French emperors, its success was universal throughout Europe. The Duchess d'Abonts died in extreme poverty on the 4th of June 1830.
K

KAFFRARIA. [KAFFRARIA.]
KAFFRARIA, BRITISH. This name is applied to a dependency or military possession, recently annexed to the Cape Colony in South Africa. The annexation arose out of the Kaffir War of 1847. For twenty years before that date the settlers in the Albany district of the Cape Colony, being near the eastern frontier, were often exposed to invasions from the Kaffirs. Successive governors of the colony—Sir B. D’Urban, Sir P. Maitland, and Sir H. Pottinger—had endeavoured in vain to suppress these raids. In 1847 Sir H. Pottinger, at the instance of the settlers, sent out his forces, which their unseated resentment against the white settlers broke out again with great force in 1850. On the last day of that year Sir H. Smith issued a proclamation from King William’s Town establishing military service in the colony, and ordering all the white colonists between the ages of 15 and 50 to rise on command to defend the frontier against the Kaffirs. The British troops suffered much annoyance and loss in the harassing bush-warfare which ensued. On the 8th November, 1851, in an encounter with the Kaffirs in the Waterhoep, Lieutenant-Colonel Fordyce and several officers and men of the 74th regiment were killed, and a considerable number wounded; the Kaffirs escaping unharmed. In January 1852 Major-General Cathcart replaced Sir H. Smith. On the 20th December General Cathcart defeated the Basutos, a Kaffir tribe, on Berea Mountain in the Orange Sovereignty, shortly after which three chiefs named Macomo, Sandili, and Kreil submitted to the British, and the war was virtually at an end. All the Kaffirs were notified to the General and the Kaffir chiefs held near King William’s Town on the 9th of March, 1853. This war cost England about a million and a half sterling. The country called British Kaffraria is a large district eastward of Cape Colony, over which the British government holds the kind of overlordship or protectorship, the precise character of which has not been very clearly defined. British military posts are maintained at various points over the area. The district is divided into counties. Buffalo River is the chief river. A town called London is to be established at the mouth of Buffalo River.

KALE, or KAIL, SEA. [CHAMBER.]
KAISARIYEH, a town in Asia Minor, is situated in a plain to the north of the Brish-Dagh (the ancient Argea) in about 36° 44' N. lat., 33° 25' E. long., and has a population variously estimated at 25,000, 40,000, and 60,000, consisting of Turks, Greeks, and Armenians. The plain is laid out in corn-fields, and screened on the east and west by low hills covered with gardens and vineyards, and the whole neighbourhood abounds with volcanic deposits. The town is surrounded by an old walled moat, and further defended by an old citadel partly in ruins. The houses, which are from 800 to 10,000 in number, are built of stone and lime, but many of them have a cracked and dilapidated appearance caused by the frequent earthquakes. The streets are narrow and dirty, the squares and market-places also abound with filth; and the naturally healthy climate is poisoned by the subterranean exhalations. The town is extremely extensive and well supplied with European manufactured goods, woollens, silks, hardware, iron, &c. The Armenian merchants display their wares in a large place called the Vint Hoste, these consist of hardware, souf-boxes, glass beads, Red Sea shells for ornamentation, paper, cards, pellocks, &c. Of native articles exposed for sale the chief are yellow berries, which are grown in the plains of Cessarea, wool, gait-nuts, goats’ hair, trapascht, cotton, skins, fur, cotton-raisons and other fruits. Among the principal structures in the town are the mosques, the convent of Siddi-Battal, and some mosques. The Armenians have a bishop and two churches in Kaisariye; the Greeks also have a church. The manufactured products of the town are chiefly yellow marocco leather, cotton stuff, and cotton-yarn.

Kaisariyeh in site and sound is identical with the ancient Cessarea, the capital of Cappadocia, which was originally called Caesarea. The city of Cessarea was situated on the Meias, now called the Kara-Su, which was surrounded by the famous Arianathe. The city was taken by Tigranes, and its inhabitants carried off to his new capital Tigranocerta. When Cappadocia was made a Roman province in the reign of the emperor Tiberius, Cessarea was made the capital. It became a place of great importance in the later times of the empire. When taken by Sapor in the reign of Valerian (about a.d. 259) it had a population of 400,000. In the reign of Justinian the walls were repaired. There are many ruins and heaps of rubble of ancient structures about the town. Cessarea gave title to a Christian bishop from an early period of the Church; it is the birth-place of St. Basil the Great, who became bishop of Cessarea, a.d. 370.
having been heard of Dr. Kane and his party, the government of the United States fitted out a relief-expedition, consisting of a small screw-steamer and a clipper-boat, under the command of Captain E. C. Crockett, in the Harriet Lane. This expedition sailed from New York on the 31st of May, 1855, and, having reached the Danish settlements, the missing party were found, and arrived at New York on Oct. 1, 1855. In May, 1856, the gold medal of the Royal Geographical Society was awarded to Dr. Kane for his distinguished services and important discoveries in the polar regions, and for his valuable memoir and charts.

In 1866 Dr. Kane published his Arctic Explorations: the Second Greenland Expedition of Sir John Franklin, in 1853-55, Philadelphia, 2 vols. 8vo. In the autumn of the same year he paid a visit to England, and being in a state of failing health proceeded thence to the island of Cuba, in hope that he might derive benefit from the climate, but died at Havana, and was buried in his father's old home, at his native city of Philadelphia, and were interred there with unusual demonstrations of public respect and grief.

A badly written 'Biography of E. K. Kane,' by W. Elder, was published in 1866.

KANSAS, a Territory of the United States of North America, established by Act of Congress 1854, occupies the country lying along the river Kansas, north of the Indian Territory, and extending northward to the Nebraska River. It is bounded on the north by the States of Iowa and Missouri, and by the Indian Territory; on the south by the Rocky Mountains, and by the States of Kansas and Missouri; on the west by the Rocky Mountains; and on the east by the States of Kansas and Missouri.

KANSAS is the 26th state in the Union, and consists of an unclaimed wilderness, over which roam tribes of native Indians in search of game. The eastern and southern portions are broad open prairies, well watered and very fertile, but thinly timbered. The centre of the Territory forms a portion of the Great American Desert, which is said to be for the most part wholly irreclaimable, and to present scarcely an oasis. On the west are outlying members of the Rocky Mountains. The chief river of the Territory is the Kansas, which rises in the head region of the Rocky Mountains, and flows through the Territories of Kansas, Nebraska, Missouri, and Iowa.

KANSAS was formed from the western part of the Missouri, in 39° 56' N. lat., 103° 30' W. long.; Smoky Hill Fork rises in the mountain region east of South Peak: their junction is near 39° N. lat., 99° 30' W. long. The united stream is known as the Kansas River. The navigable Kansas begins at the confluence of the Osage and Kaw rivers, in 39° 56' N. lat., 94° 32' W. long. It has a full body of water, is 340 yards wide at its mouth, and is said to be navigable for steam-boats for 150 miles, and for keel-boats, with its fords, for some hundred miles higher. Republican River, the principal tributary, receives on its right side two considerable affluents, Solomon's Fork and the Grand Saline. Numerous smaller tributaries swell the main stream and its affluents. The chief of the secondary streams belonging to this Territory which fall into the Missouri are the Nemahaw and the Independence. The Missouri itself forms the eastern boundary of Kansas, and affords an invaluable outlet for its products. The Kansas River, on the northern side of the Territory, is a very wide but shallow river, with a rapid current and a bed full of shifting sand-banks: it is navigable by steam-boats for about 50 miles. The great emigrant and freight routes to Oregon, Utah, and California lie across the Territory of Kansas, and follow the courses of the streams either as their affluents or their principal rivers.

As far as the country has yet been examined geologically, its southern and eastern parts appear to belong to the Lower Carboniferous system; the rocks consisting largely of mountain limestones and sandstone. In the south-eastern corner of the country there are some portion of the basin of Upper Carboniferous Rocks, or Coal-Bed of the Indian Territory. The western and northern portions of Kansas seem to consist chiefly of strata of the Cretaceous group, but we have no detailed account of the rocks. The country, with the exception of the central waters, is very rough and hilly. The eastern portion is under a very hot climate, while almost every part is well watered. The prairies are of the best kind, but are deficient in timber. The river bottoms have a rich alluvial soil. The few settlers who have been established within the Territory are said to report very highly of its capabilities, but as yet even
the surface of the country is very little known. The only settlement beyond the recently-founded city of Worcester and a few scattered farm-houses, is the military station of Fort Winfield Scott. The vast tract known as Nebraska, including an area of upwards of 136,000 square miles, of which Kansas forms the southern part, was a portion of the country purchased by the United States from the Republic of Mexico in 1848, and which has been held by the United States since that time. The region has been explored by several parties, but the discovery of coal and extensive tracts of prairie land, with the discovery of gold in the western part of the country, has attracted a great number of settlers. The region is now divided into several counties, and the population is rapidly increasing. The region of Kansas is largely agricultural, and its principal products are wheat, corn, and cotton. The region is also rich in minerals, and the discovery of gold and silver is a recent development.

The region of Kansas has been the scene of much controversy and conflict, particularly in the case of the Kansas-Nebraska Act of 1854. The region was originally part of the Mexican Cession, and was claimed by the United States under the terms of the Treaty of Guadalupe Hidalgo. However, the region was also claimed by Mexico, and the conflict between the two nations led to the Mexican-American War.

(Arpa-Se), and the Marvysas (Tahina-Se), which last rises in a region called Idrissa by Herodotus (v. 118), and is skirted on its western side by the range of Laismus. Except the Calbis, which is rocky, and the Idrissa, which is pyramidal and rises to the south coast. The Seamander, which carries off the drainage of the greater part of Caria, flows in a west-south course, and in ancient times entered the sea to the north of Mount Phoinix, which is now filled up by the deposits of the river.

On the south coast, east of the Rhodian Chersonese and the lofty Mount Phoinix, was a land-locked bay, at the head of which stood the town of Phusys. There was a rock in this bay, near the eastern part of it, called Paneumus, which was also a Phocaean settlement. A small promontory, the head of the Bay of Panomus and the west of the Caib is a large lake six or eight miles across, and with a number of small streams running into it; a channel twelve miles in length connects it with the sea. Fellowes says its waters are brackish. All the southern coast of Caria eastward from Mount Phoinix, and extending to the mountains inland belonged to the Rhodians, and was called Peria. This district is very beautiful, and contains many fertile tracts. The irregular coast of Caria is most picturesque, indent or bordered with coves, bays, and inlets, where the land is well wooded, are in parts diversified by extensive ancient ruins, and belts by numerous islands.

Though Caria is extremely mountainous it contains some extensive plains. They are fertile, and form the chief homes of the people of Caria. A large one is known as the Aetas, in the valleys of the Seamander and its feeders. The mountains are in most parts well clothed with timber; furs, oaks, and plane trees being the prevailing species. The chief products are wheat, figs, olive oil, fruit of all kinds, and wine. The vine is trained to the highest trees. The wine of Cnidus was celebrated in ancient times. The palm-tree and the orange grow luxuriantly. Cattle are fed on the mountain pastures, and sheep are numerous; the green slopes along the valley of the Marvysas are covered with flocks, the climate owing to the invigorating effects of the sea being the mildest, the heat, while the high lands are cold, wintry, and snow-covered. At the source of the Meosynus the winteringers to March or April. The limestone which everywhere abounds affords excellent material for building. Among other mineral products Fellowes mentions iron-stone of great purity as abundant between Stratonicia and Myliasa, mica-schist, marble, &c. Warm springs abound, and there are gaseous flames.

The Carians maintained that they were an autochthonous people, and that their original home was the Carian peninsula. According to Cretan accounts they originally inhabited the Aegean islands, were subject to Minos, whose ships they manned, but they paid no tribute; and that driven from the island by the Cretans, they settled in Valaia, where they displaced the Leleges and Palaeagi. Homer mentions the Carians with the Leleges, Cacoones, and Palaeagi, among the auxiliaries of the Trojans; and they were probably all continental people and related to each other. The Cauniss, whose town Caunus was on the south coast, spoke a language akin to that of the Carians. Thucydides says that the early inhabitants of the Aegean islands were Carians and Phenicians, and that they were pirates. There seems little doubt from Thucydides (1, 5) that the Carians with some other people occupied the island of Delos at some early period. In Homer's time the Carians occupied Milearus, the banks of the Meander, and the heights of Mycale to the north of the river. The Ionian emigration drove the Carians from Mycale near which Priam was built, from Myras, and from the city of Milearus. The Doriens dispossessed them of Halicarnassus, Cnidos, the Triopian Chersonese, and probably from the island of Kos. The south coast was probably seized by the Rhodians about the same time. The Carians were driven into the Gulf of Cyme, but not all, for in the time of Xerxes the Carians furnished 70 ships to the Persian fleet, while the Dorian settlements supplied only 30 ships. North of the Meander and in the north of Caria were other Carian colonies, some in the interior, some between the Carians and their neighbours; but they maintained their language, and in the interior the population was pure Carian. They lived in small towns or villages, and formed a federation with common religious rites to Zeus Chryseus. The federation was called Chrysceus; its place of meeting for sacrifice and deliberation was the spot where the Macedonians after the time of Alexander founded Stratonicia.

Caria was included in the kingdom of Creusa, on whose defeat by Artaxerxes the Persians claimed title under the Persian domination. The Ionian revolt (a.c. 499-494) the Carians fought bravely side by side with the Greeks, but were at last compelled to submit. Under the protection of Persia, Caria was ruled by a family of the name of Artaxerxes. Artaxerxes, who accompanied Xerxes to the battle of Salamis, with five ships, was one of these petty sovereigns. The Athenians afterwards made the inhabitants of the coast tributary, but the Carians of the interior maintained their independence. In the time of Alexander the strong towns of Alius appear, in consideration for which he restored them to the royal authority of which they had been deprived. Caria afterwards became successively subject to the Greek kings of Egypt and Syria. The Carian states having defeated Antigonus (a.c. 190) shared Caria between Eumenes king of Perga and the Rhodians, but left certain towns free. About a.c. 129 Caria was added to the Roman province of Asia. The Carians were a warlike people, not addicted to commerce like the Greeks; they hired themselves as mercenaries, and served under the kings of Egypt.

Among the towns of Caria were Cnidos and Halicarnassus, which were members of the Dorian hexapolis in Asia. Halicarnassus, or Doris, the capital, was founded in the 7th century B.C., and is the birthplace of Herodotus and Dionysius the historians. It was founded by a colony from Trozenes in Argolis, was the largest and strongest city in all Caria, and was the seaport of the Carian confederacy, the MESI home of Hestia. One of its rulers, Artemisia, wife and sister of Mausolus, erected in his honour the celebrated sepulchral monument called the Mausoleum, of which there are still remains as well as of the ancient walls. Some interesting sculptures, supposed to have formed part of the Mausoleum, are now in the British Museum. Halicarnassus continued to be a stronghold of Perga till the time of Alexander, who after a long siege burnt the city, but was unable to take the acropolis. Though afterwards rebuilt Halicarnassus never again became a power. Among the other towns were Alabanda, now supposed to be Arab-Hisra, on the Taphis, or Marvysas, where are remains of a theatre and other buildings; it was noted for its luxury; Cokseis, higher up the Marvysas, identified by Leake with the village of Taphis where Pococke found considerable remains; Labrando, to the south-west of Alabanda, famous for its Carian temple to Zeus Stratios, to which the Carians went in procession from Myliasa along the sacred road which was about 30 miles long (its precise course is unknown) which Fellowes erroneously takes for Labrando was Euromus, where are the remains of a beautiful Corinthian temple. Myliasa, in the interior and to the north of Halicarnassus, was the residence of the Carian kings from the ruins of the old town. There are still many beautiful remains of ancient architecture at Millassaa, which was visited by Fellows. East by south from Myliasa was Stratonicia, which was either founded or rebuilt on a spot called Idriss by a Macedonian colony after the time of Alexander. Stratonicia is identified by Fellowes with Esky-Hisra, which stands in a delightful country. There are remains of several temples, the marble walls of which are covered with inscriptions. The walls of the ancient town extend far beyond the line of Esky-Hisra.

Cumaus, the chief town of the Cauniss, was a place of considerable trade, on the south coast in the Rhodian Peraea. It was the birth-place of the painter Protopagenes, and famous for its figs. It was for a long time subject to the Rhodians. In the massacre of the Romans in Asia in the time of Mithridates Eupator, the Cauniss distinguished themselves by their ferocious cruelty to their victims. On a height above Caunus is said to be the tomb of Seus. Between Caunus and the Gulf of Glanuss was Calypsa, which has not been identified, but is supposed to be in the basin of the Talaman, or Dolonom-Chai, the Calbis of Siras and the lauds of Livy.

In the north-east of Caria, near the Phrygian frontier, is Asty, which is supposed to be Mycale, and Mesmore; its remains, which are described by Hamilton and Fellowes, consist of the massive walls of the acropolis and an inner castle, some subterranean buildings, a stadium, and a small theatre. South of Asty, on the right bank of the Mysus, stood the city of Aphrodisias, now Ghers, where are remains of a beauti-
tiful Ionic temple of Aphrodite, from whom the town was named. There was a city *Pamphile*, probably not far from Aphrodias. Fellowes ("Asia Minor") says that Ophria is the representative of the ancient town of Paphos, and that Mount Cadmus, near the confines of Caria, Lydia, and Phrygia, was famous for its hot springs on the banks of the Meander, by which its site has been identified. Hamilton's "Researches in Asia Minor; Dictionary of Greek and Roman Geography." 

North of the Meander were *Tripolis*, near the point where the river enters the plains (28° 1' N. lat.), where are remains of the ancient town, and the ruins of the ancient city of *Musauros*, west of Tripolis and north-east of the modern Nazeli, and near the modern village of *Mastaura*, has some ancient ruins, most of which are overgrown with underwood, and a fine spring of cold water: *Trudel*, situated on the plateau of *Musauros", below the modern Aïdin (a town of about 6000 houses); the plateau is covered with ruins, among which the Turks have quarried materials for the houses and walls of Aïdin; the most remarkable ruin is that of a palatial structure, which is probably not ancient: *Magnesia" farther west near the mouth of the Lethys in the Meander: and *Priene", on a rocky site near the modern town of Samos, where many ancient walls remain, and a theatre cut out of the rocky hill. Several of these towns were fortified by the ancient Greeks, and Lydus, in which later times they seem to have belonged.

Along the west coast beyond Halicarnassus were *Myndus", once the capital of Caria: *Corianda", a city which seems to have been an early centre of trade and commerce, which the main road of the two parts being united by a causeway (a now narrow sandy isthmus), alongside of which was the harbour which Leake takes to be that of Pasha-Limani: *Bargypia", on the southern shore of the lagoon of the Iassian Gulf, between Myndus and *Iassus", celebrated for its statues of Artemis Orithya; upon which, though exposed to the open sky, neither rain nor snow (it was said) ever fell. *Iassus", or *Iassos", now Askem, *Asyn Kales", on a small island at the head of the Iassian Gulf, which is formed of the same red volcanic colous as the town, contained considerable Christian and Mohammedan settlements in the lonic emigration under Neleus; it became a wealthy place owing to its fisheries; part of the city walls and a theatre cut out in the side of a rock still remain. *Brachiside" was famous for its crag and temple of Apollo Didymus, of which there are still some remains; the temple was robbed and burnt by the Persians (s.c. 494), but it was afterwards rebuilt. A sacred way led from the sea to the temple bordered with monolithic statues seated on chairs. There was a modern "Imitation of the avenues of the temples of Egypt" (Leake, "Asia Minor"). *Branchide" near a harbour, called *Panormus", on the south of the *Poseidoneum*. *Miletus", one of the most ancient and flourishing towns of Caria and famous for its schools of oratory and philosophy, and for the numerous colonies founded by it on the Black Sea, was situated on high ground on the south bank of the Meander and near its mouth. Its citizens were great traders and powerful by sea. They carried on trade along the Lydian coast. It was subjected to the Persians by Cyrus the Great, and, notwithstanding internal dissensions continued prosperous until the Ionian revolt, instigated by its tyrant *Aristagoras*; this event brought down upon it the vengeance of the Persian, who utterly destroyed it (s.c. 494). It was rebuilt, and made a long resistance to the army of Alexander; but it never recovered its former importance, although it was a prospous place under the Romans. Its site is marked by the modern "Miletus", where are seen the remains of an enormous theatre, an agorax, and a Christian church formed out of a Greek temple. South-east of Miletus, in the interior near the brackish lake of Bafli, which is probably part of the ancient Lake Mydonius, was *Heraclia" on the west end of Mount Lattara, where the ruins mark the spot. Near it was shown the cave of *Endymion". To the north end of this lake, near the Meander, was *Mydas"; and on the east side of Mount Lattara lay *Amusus", ruins of the city which is still a ruin. (Pococke; Leake, Asia Minor; Sir C. Fellowes, Asia Minor; Hamilton, Researches in Asia Minor; Dictionary of Greek and Roman Geography.)

K.B.S., a town in western Armenia, is situated in a high rugged country, and is about 60 miles from the level of the sea, on the Arpa, a feeder of the Araxes, about 100 miles straight-line distance N.E. from Erzerum, N.W. from

Baysand, and S.E. from Batum on the Black Sea, in 40° 27' N. lat., 43° E. long., and has about 15,000 inhabitants. It is about 46 miles W.S.W. from the Boghazkeui, and about 25 miles N. of Lake Urmia. It stands in a rocky amphitheatre of black basaltic hills, and has a dark dismal look, from the total absence of trees, and from the circumstance that all the houses are built of black basalt. It contains 1000 men and 1500 women, and is surrounded by a wall, the remnants of which are visible from its position on the boundary of Caria towards Phrygia (Kasim olep).
turned to England in 1792. He was placed, through the influence of his brother, J. P. Kemble, in the General Post-Office, London, but soon resigned his situation, and after a short stay at Covent Garden. He first appeared on the public stage at Sheffield, as Orlando in 'As You Like It.' He had engagements afterwards at Newcastle and other towns. On the 21st of April, 1794, he made his first appearance in London, as Malcolm, in the opening of the new Haymarket Theatre. He afterwards acted at Drury Lane, Macbeth, Mrs. Siddons Lady Macbeth, and Mr. Palmer Macauley. He continued for a considerable time to play secondary characters, but gradually improved in his art. On the 20th of November, 1796, he performed George parchment, at Drury Lane, Mrs. Siddons taking the character of Millwood. In 1797 he was engaged at the Haymarket Theatre, where in 1800 he brought out his adaptation of Mercier's 'Deserter,' under the title of 'The Point of Honour,' which was performed successfully, and continued to be played in the theatre of the 2nd of July, 1806, he married Miss Marie Theresia De Camp, of French parentage, but born at Vienna in 1774. Miss De Camp was engaged by her father as a danseuse at the Opera-House, London, at a very early age. Her father died when she was in her twelfth year; she was then patronised and instructed by some ladies, and had become, when Charles Kemble married her, a favourite actress in the wolk of high comedy, and she so continued as Mrs. Charles Kemble. She was engaged to play the part of Lorenzo in 'Othello' on the 6th of September, 1838. In 1807 Mr. Charles Kemble brought out with success at Covent Garden 'The Wanderer, or the Rights of Hospitality,' which is an adaptation of Kotzebue's 'Edvard in Schotland'; and in 1808, at the Haymarket Theatre, he played 'Monsieur Suzanne,' or 'Counterplot,' an adaptation of a French piece called 'Le Portrait de Michel Cervantes.' Three or four other dramatic pieces from the German and French, which he brought out afterwards, were less successful. Meantime he continued to improve in his profession, took a wide range, and in some of his characters was without a rival. Among his best characters may be mentioned Orlando, Falcondridge, Cassio, Leon, Benedict, Young Mirabel, Mercutio, Petruchio, Archer, Rambert, and others in 'Elisabeth.' These characters his handsome features, fine voice, and tall well-formed athletic person, peculiarly fitted him. He closed his career as an actor on the 10th of April 1840, shortly after having been appointed to the office of Examiner of Plays. He appeared in public occasionally afterwards as a reader of Shakspeare. During some of his latter years he suffered the inconvenience of deafness. He was well acquainted with modern languages, and a tolerable classical scholar. He was born at London, on the 18th of November, 1814, aged seventy-nine years within a fortnight. Mr. Charles Kemble left one son and two daughters. His son, John Mitchell Kemble, is noticed in a separate article. His eldest daughter, Frances Anne Kemble, known as Fanny Kemble, appeared on the stage, and was for some time separated. The other daughter, Adelaide Kemble, distinguished herself as an operatic singer. She became the wife of Mr. Sartoris, and then quitted the stage. KEMBLE FAMILY. The Kemble family form probably the most extraordinary group of actors and actresses ever known. Macklin, when nearly 100 years of age, addressing John Philip Kemble, said, 'Sir, I have known your family from generation to generation. I have seen you act, young man; and I have seen your father, sir; and I have seen your grandfather, sir. Sir, he was a great actor.' Of the grandfathre there appears to be no record but the testimony of Macklin. The father, Roos KEMBLE, was born on the 1st of March, 1731, in the city of London, and was the author, actor, and manager of a company that performed in the principal towns of Wales and the west of England. He married in 1753 Sarah Ward, born September 2nd, 1735, at Clonmel in Ireland. She was also an actress. They had two sons, Charles and John. Their son, Charles, was the second eldest. [SIDDONS, MRS. SIDDONS, KEMBLE, JOHN PHILIP.] Charles Kemble was the 11th child and youngest son. Roger Kemble died in 1809, and Mrs. Sarah Kemble in 1806. STEPHEN KEMBLE (George Stephen Kemble), the third of the children, was born on the 3rd of May 1758, at Kington, in Herefordshire. He was intended for the medical profession, and was placed with a surgeon at Coventry, but gave the preference to the stage. After a course of stock-practice in the country he made his first appearance in London, at Covent Garden, on the 24th of September, 1783. In the same year he married Miss Satchell, a favourite actress. After acting for some time at Covent Garden he was engaged at the Haymarket Theatre. He first appeared in a part which he afterwards performed so remarkably that performed at Edinburgh and Glasgow, and subsequently of another that acted at Newcastle, Durham, Sunderland, Lancaster, and Whitehaven. He was a good actor, but became so busy in person as to be almost unfit for any character in the repertoire but Prune in 'The Merchant of Venice.' He had a good voice and a good leg, and died on the 8th of June 1822, at the Grove, near Durham. FRANCES KEMBLE, the fourth child of Roger Kemble, was born on the 28th of December 1759, in the city of Hereford. She also became an actress, and performed in London; but having become infected with 'Inkle and Yarico,' a few days after which she was attacked by inflammation of the bowels, and died on the 6th of June 1822, at the Grove, near Durham. FRANCES KEMBLE, the fifth child of Roger Kemble, was born on the 2nd of April 1761, at Warrington, in Lancashire. She was apprenticed to a mantua-maker, but left that occupation for the stage. After some practice in the country, she made her first appearance in London at Drury Lane Theatre, on the 22nd of February 1783, as Poria in 'The Merchant of Venice.' After repeating Poria she repeated the part of Prune in 'The Merchant of Venice.' She then retired from the stage. She had a good voice and a good leg. In face, figure, and voice she bore a striking resemblance to Mrs. Siddons. On the 21st of June 1785 she was married to Charles Edward Whitchot, an actor and joint-manager of a theatrical company in the north of England, known as the London and Provincial Company. Mr. Whitchot died in 1807, and the stage. Mr. Whitchot died about 1850. Mrs. Whitchot was much admired in society for the liveliness of her conversation. She died on the 27th of February 1836. The other children of Roger Kemble died young, except a daughter, Anne, born in 1764, who was alive in 1834. KEMBLE, JOHN MITCHELL, well known as one of the chief Anglo-Saxon scholars of his age, and also distinguished as a wit and a polemicist, was born at London, on the 12th of November, 1787, and was educated at Trinity College, Cambridge, where he took the degree of B.A. in 1803, and that of M.A. a year or two later. From the very first his studies were directed towards the Anglo-Saxon language; this was due to the influence of his father, and to his acquisitions in this department by the publication of 'The Anglo-Saxon Poems of Beowulf, the Traveller's Song, and the battle of Finnesburgh, edited, together with a Glossary and an Historical Preface.' The work reached a second edition in 1802, when an additional volume, containing 'A Translation of the Anglo-Saxon Poem of Beowulf, with a Glossary and Notes," was appended to the first. The more important of Kemble's subsequent works were the 'Codex Diplomaticus Anglorum,' edited John M. Gathorne, vol. 1, 1830, vol. ii. 1840; 'The Anglo-Saxon Charters,' the 'Vercelli Codex: Poetry of the Codex Vercellensis, Anglo-Saxon and Latin, with an English translation," published in 1847, and 'The Aneis of 843 as one of the works of the Society for the 'Dialogue of Solomon and Saturnus, with an Historical 'Introduction and English Translation,' published in 1848 by the same society, an edition of T. W. Tyndall's 'Considerations upon the Government of England,' published in 1849 by the Camden Society, 'History of the English Commonwealth till the period of the Norman Conquest," published in 2 vols. in 1849. This last work comprehends the main results of Mr. Kemble's Anglo-Saxon and historical studies. Mr. Kemble was editor of the 'British and Foreign Quarterly Review,' a periodical of the highest class, which exercised considerable political and literary influence, but ceased to exist about the year 1845. He held the office of Examiner of Plays under the Lord Chancellor, his acting assistant in this office being Mr. Donne. Mr. Kemble was a Fellow of
various learned societies, including the Academies of Sciences of Berlin and Munich, and the Historical Societies of Stock- 
holm and Copenhagen. During the latter part of his life he was 
KENDIF, OR KENVIG. [GLAMORGANSHIRE.]
KENMAR, county of Kerry, Ireland, a market and 
and town, and the seat of a Poor-Law Union, is situated at 
the head of Kenmare Bay. The town occupies the site of an 
castle of the MacCarthy's, on the north side of the 
11° 52' N. lat., 9° 34' W. long, 16 miles 
S. by W. from Killarney, 163 miles S.W. from 
Dublin. In 1851 the population was 1501.
Kenmare Poor-Law Union contains 16 electoral divisions, with 
an area of 195 square miles, and a population in 1861 by 
railway enumeration was 10,483. This place was called Dunleary 
till September 3rd, 1821, when the name was changed to 
Kingstown to commemorate the embarkation of George IV. 
for England, which circumstance is recorded on a granite 
monument in the churchyard of the Protestant church. 
Aristocratic flocks of sheep in the immediate vicinity of this 
mere fishing village and collier haven till the new harbour-
works were commenced in 1817. Since then the town 
has been greatly extended, so that Kingstown may now be said 
to include not only Dunleary, but also Monkstown, Balloolock, 
and Dalkey. The harbour is formed by two piers inclosing 
an area of 250 acres, with a depth of from 16 to 27 feet, 
and approaching each other within a distance of 760 feet. 
The eastern pier, on the extremity of which there is a bright 
masted light, is 280 feet long; and along both piers there are quays 40 feet wide, 
which are protected from the sea by parapets 9 feet high.
The harbour has not proved so useful as was expected, 
or the number of vessels being much less than anticipated.
As number of vessels that entered Kingstown harbour in 
1851 was 3128, of the aggregate burden of 207,367 tons, exclusive 
of men-of-war, cruisers, and mail packets; of this number 1117 
were vessels trading to or from the port of Dublin. The 
chief exports are coal, salt, and vegetable oil, and the chief 
customs being paid by coal, iron, and timber. The beauty of the 
situation, the salubrity of the air, the picturesque country around 
the town, the arrival and departure of the steam-vessels, 
and the bustle connected with the shipping, have contributed to 
make Kingstown a place of great resort; it is also much fre-
quently as a watering-place. The principal street is George's 
street, extending above half a mile in length. There are 
numerous avenues, terraces, and parades, some of which are 
lined with magnificent trees, and the imperial avenue of 
the parish church, which is at Monkstown, there are a large 
and handsome Roman Catholic chapel, St. Mary's convent, 
a Free church, the Mariner's church, and places of worship 
for the several denominations. The terminus of the line 
from Dalkey, is in front of the harbour.
There are a petty sessions court-house, police and coast-
guard stations, a savings bank, lying-in hospital, dispensary, 
National and other schools, and commodious accommodations. 
The town is lighted with gas, and partially paved. The 
paving and lighting of the town is managed by a board of 15 
commissioners. There are remains of old castles at Monkstown 
and Balloolock, and of three in the village of Dalkey. King-
town is the station of the Royal St. George's Yacht Club.

KINGTON. [HEREFORDSHIRE.]

KINNIC or QUINIC ACID. [CHEMISTRY, S. 2.]

KIRBY, THE REV. WILLIAM, one of the most dis-
tinguished persons of his age, possessed a high knowledge of entomology. He was the grandson of John 
Kirby, a miller at Wickenham Market, in Suffolk, and 
the author of the 'Suffolk Traveller,' which was published in 
1765, and was a work of great repute in its day. Joshua 
Kirby, a brother of the father of the subject of our notice, 
was the friend of Gainsborough the artist, and distin-
guished as an architectural draughtsman, and the author of a 
work on Perspective. William Kirby, his father, was a 
clergyman, and writer of a well-receivedisValid, the midst of the elevated chalk downs, on the line of an 
anticlinal axis passed east and west. The anticlinal axis passes through the middle of a valley (hence called a 'valley of eleva-
tion,' or, more properly, an 'island' appears; and it might seem 
only on a view that the disconnection of hilly areas is simply 
owing to elevation and fracture, but by considering the 
areas and slopes of the strata, in plans and sections on a
where it appears he did not distinguish himself. From thence he was entered at Caius College, Cambridge. Here again he failed to distinguish himself, for Cambridge had at this time a great number of students. In 1742 he entered Ripley of Debenham. At this time he became acquainted with Dr. C. M. Swain, whose writings on controversial divinity were highly estimated. Mr. Kirby had however no taste for polemics, and although he never neglected the duties of his office for the pursuit of natural history, he determined to give up botany and decided, that he published very little on subjects directly connected with his profession as a clergyman.

Left to the natural bent of his genius, and surrounded with objects of natural history, his early love of plants was rekindled, and he cultivated a knowledge of the plants of his neighbourhood. An accident drew his attention to insects. "About half a century since," he says, "I obtained a friend in 1838, observing accidentally one morning a very beautiful golden bug crossing the sill of a window, I took it up to examine it, and finding that its wings were of a more yellow hue than was common to my observation of these insects before, I was anxious to examine any other of its peculiarities, and finding that it had twostyles, I supposed that the captured animal was imprisoned in a bottle of gin, for the purpose, as I supposed, of killing it. On the following morning, anxious to pursue my observation, I took it again from the gin and laid it on the window-sill to dry, thinking it would be more spirituous to him. I then made a spirit of it, and hence commenced my further pursuit of this branch of natural history." These facts were communicated to Dr. Owyn of Ipswich, who was a good naturalist, and led him to recommend to his young friend the pursuit of entomology. So diligent was Kirby in the pursuit of his new science, that we find him warmly taking up the cause of natural history science, and becoming one of the first members of the Linnaean Society, founded by Sir James Edward Smith in 1787, being one of the original members of the Scientific Committee of the Linnaean Society. It was entitled 'A description of three new species of Hirudo,' and was published in the second volume of the Transactions. His next paper, which was published in the third volume of the same Transactions, was 'A History of three species of Cassida.' In the same volume is a letter to Mr. Marsham, containing observations on the Insects that infested the Corn in the year 1786. He became early alive to the importance of making the pursuit of entomology of practical value, and that it was important to study the insects which attacked wheat and other plants of importance to man. The last paper was followed by others on the Tipula Tritica, on Insects that prey upon Timber; and in the fifth volume of the Linnaean Transactions is a paper entitled 'Observations on the Lepidoptera' and a table of the nomenclature of the external parts of these insects. These and other papers indicate great accuracy of observation, and prepared him for a work of higher and more important scientific interest. The family of Hemiptera, including the bees and wasps, had been but imperfectly studied in this country, and he devoted himself to the production of a separate and complete work on English Bees. This work was published at Ipswich, in two volumes, with plates, in 1803, and was entitled Monographia Apum Anglie, or an attempt to divide into the natural genera and families such species of the Linnaean genus Apis as have been discovered in England, with descriptions and observations. This work embraced also general remarks on the class Hymenoptera, and a table of the nomenclature of the external parts of these insects. This work gave him a high position amongst the naturalists of Europe, and brought him into correspondence with Fabricius, Latreille, and other naturalists on the continent of Europe, as well as all the more eminent naturalists of his own country. It was followed by several papers, containing important additions to the literature of entomology, but was perhaps surpassed in scientific interest by his discovery of the genus Stylus, which he indicated as the type of a new order of insects, to which he gave the name of "The Order of Stylus," to which these insects were found parasitical during their larva state in the bodies of bees, and the novelty of their history and beautiful forms excited a lively interest in the entomological world.

But whilst these discoveries were going on, he was preparing for a work by which his name became more widely known and imperishably associated with the popular literature of his country. We allude to the 'Introduction to Entomology,' which he published conjointly with Mr. Spence. This work was written with Mr. Kirby's assistance, and was commenced in 1806, and resulted in Mr. Spence proposing in a letter dated November 23, 1808, that they should write in partnership a "popular Introduction to Entomology." This proposition was readily acceded to by Mr. Kirby, and in 1816 the first volume of the work appeared. It went through three editions, and in 1817 the second volume was published. On account of the illness of Mr. Spence the third and fourth volumes did not appear till 1858. This work created a great deal of interest among the students of science and in the production of our language, and few scientific publications have been so extensively read. Since the death of Mr. Kirby, Mr. Spence has published a seventh edition, to which is added an appendix giving an account of the origin and history of the work. It is written in the form of letters, and gives in a familiar style an account of the structure, habits, and forms of insects. It is a model of the manner in which works on natural history to be popular should be written, and is almost exhaustive of the subject of the habits, uses, localities, and instincts of insects. Of the fifty-one letters of which this work consists, it appears that twenty were written by Mr. Kirby, nine by Mr. Spence, and twenty-two by the two authors conjointly.

In 1830 Mr. Kirby was applied to by the trustees appointed under the will of the late Earl of Bridgewater to write one of the works since so well known as the 'Bridge-water Treatises.' Although he was then in the seventieth year of his age, the production of such a work was so congenial to his spirit and inclination that he undertook it; and hence commenced all his natural history researches, that he at once consigned. The subject was the 'Habits and Instincts of Animals.' From his previous history it would appear that Mr. Kirby had not had such extensive opportunities of studying the other groups of animals so accurately as he had done insects. It is therefore, especially considering his age, not surprising to find that this work did not equal in merit his previous productions. It contains, however, a great number of interesting facts and observations, with abundant evidence, in reference to all departments of the animal kingdom, and the spirit in which it was written was eminently in accordance with the object of the founder of the treatises.

Mr. Kirby's other principal labours included the following:—A Description of several new species of Insects collected in New Holland by Robert Brown, Esq., F.R.S. ('Linn. Trans.' xii.); 'An Account of the Animals seen by the late Northern Expedition whilst within the Arctic Circle,' 4to, London, 1831, being the Report of the Polar Society, which attacked wheat and other plants of importance to man.

In 1834 a museum of Natural History was founded at Ipswich; he was present at the opening of this institution, and held the office of President till his death.

Mr. Kirby was twice married, his second wife being Miss Rodwell of Ipswich, to whom he was married in 1816. She died in 1844. He had no family by either wife, and died on the 4th of July, 1850, at the great age of 83 years. He was the author of 'A History of Life,' to which these insects were found parasitical during their larva state in the bodies of bees, and the novelty of their history and beautiful forms excited a lively interest in the entomological world.

KIRKBY STEPHEN. [ WELSHPOOL SHROPSHIRE.]

KIRKWALL. [ ORKNEY ISLANDS.]
Mr. Grove on an extensive tour to the East, during which he was to instruct Mr. Grove and Mr. Arstache, the Calmuck Tartars, the Caucausians, Armenia, Persia, and Baghdad. At this latter town he was detained during the plague. Mr. Grove lost his wife, and Kittie thence returned to England.

In July of that year, Mr. Woolcombe of Plymouth wrote a letter of introduction for him to Mr. Coates, the secretary of the Society for the Diffusion of Useful Knowledge, recommending him for employment on the ‘Penny Magazine.’ Mr. Coates was an excellent writer, by himself, in which he proposed a plan of writing his travels, either in the form of weekly numbers, “like the ‘Penny Magazine,’” or as volumes of the ‘Library of Entertaining Knowledge.’ Mr. Coates referred him to Mr. John Knight, who had originated the ‘Poles,’ and who thought the society could not undertake the travels in the ‘Entertaining Knowledge.’ On the 19th he wrote to Mr. Knight, stating his willingness to use his journal for separate papers in the ‘Penny Magazine.’ On the 20th he called on Mr. Knight; the conversation was carried on by Mr. Kitto speaking, which he did very imperfectly, and Mr. Knight writing. A few letters afterwards passed, specimen articles were sent and approved of, and on the 4th of August he was engaged, at £30 per annum, on the same terms as a salary, saying that “the terms offered would be sufficient not only for my present but my prospective wants.” He continued for two years in various literary employments. In 1836 Mr. Knight formed the plan of printing the whole of Mr. Kitto’s journal, but when Mr. Kitto if he would like to furnish a few of them, illustrating particular passages from what he had observed in his travels. He not only eagerly embraced the proposal, but earnestly entreated to be allowed to undertake the responsibility of the entire work. A writer’s men prepared, and eventually it was approved of; the whole was then entrusted to him. The ‘Pictorial Bible’ was finished in 1838. During its progress, for about two years and a half, Mr. Kitto received an annual payment of £100, and an additional sum, which seemed to him a little fortune. In 1838 he embodied a great portion of his experience in Persia in two small volumes, ‘Uncle Oliver’s Travels.’ In 1839 and 1840 he was engaged in writing the ‘Pictorial History of Palestine,’ also for Mr. Knight. He was entitled to a new edition and he received for these and subsequent works, payments according to the highest scale of literary remuneration. From 1841 to 1843 he found employment with Mr. Fisher in the ‘History of Engravings,’ in 3 vols. In 1843 he wrote a ‘History of Palestine,’ published by A. and C. Black of Edinburgh; and ‘Thoughts among Flowers,’ published by the Religious Tract Society. In 1844 the degree of D.D. was bestowed upon him, and the University of Edinburgh presented him with a gold medal.

In 1845 he renewed his connection with Mr. Knight, and prepared ‘The Pictorial Sunday Book,’ and wrote ‘The Lost Senses—Deafness and Blindness’ for ‘Knight’s Weekly Volume.’ In this year he commenced the ‘Critical and Biblical Literature,’ published by A. & C. Black. In 1847 he undertook for Mr. Knight a new edition of the ‘Pictorial Bible,’ of which he greatly improved the notes, and which was completed in four volumes in 1840. For this revised edition he received upwards of £600. It is right to mention, that although Mr. Kitto in his latter years was uneasy in his circumstances, his difficulties were not caused by inadequate payments by his various publishers; nor did he sustain any loss on them, as is stated in his ‘Biography.’

In 1848 he had engaged on the manuscript account the ‘Journal of Sacred Literature,’ which was continued periodically under his editorship till 1853, but he says himself that it never produced him any profit. He also engaged in various other works, among the most considerable of which were ‘Daily Bible Illustrations,’ two series in seven volumes, of which the first series appeared in 1849–51, and the second in 1851–53. In February 1854 he was attacked by a paralytic stroke, from which he never completely recovered, and on January 4, 1855, he died at his residence at Balington, being unequal to his work, he returned to England in February 1855. In the following May he agreed to accompany Mr. Grove on an extensive tour to the East, during which he was to instruct Mr. Grove and Mr. Arstache, the Calmuck Tartars, the Caucausians, Armenia, Persia, and Baghdad. At this latter town he was detained during the plague. Mr. Grove lost his wife, and Kittie thence returned to England.

Mr. Woolcombe of Plymouth wrote a letter of introduction for him to Mr. Coates, the secretary of the Society for the Diffusion of Useful Knowledge, recommending him for employment on the ‘Penny Magazine.’ Mr. Coates was an excellent writer, by himself, in which he proposed a plan of writing his travels, either in the form of weekly numbers, “like the ‘Penny Magazine,’” or as volumes of the ‘Library of Entertaining Knowledge.’ Mr. Coates referred him to Mr. John Knight, who had originated the ‘Poles,’ and who thought the society could not undertake the travels in the ‘Entertaining Knowledge.’ On the 19th he wrote to Mr. Knight, stating his willingness to use his journal for separate papers in the ‘Penny Magazine.’ On the 20th he called on Mr. Knight; the conversation was carried on by Mr. Kitto speaking, which he did very imperfectly, and Mr. Knight writing. KOBELLITE. [MINERALS, S. 1.]

KOLLAR, JAN, a poet and preacher, the originator of the idea of the "Royal Union," or "Brotherhood of July 1789," according to Jungmann's "History of Bohemian Literature," was born at Mocowchow, in the county of Trenthachin in Hungary, being born a Slovak, or one of the Slovak race of northern Hungary, who speak a language akin to that of their neighbours, the Moravians, who, according to P. Junghans and Jena, he became in 1819 pastor of a Slovakian evangelical congregation at Pesti. In 1832 and 1827 he issued as two volumes, under the title of 'Narodnice Zpiselanky,' or "National Songs," an interesting collection of the popular poetry of the Slovaks, which reached a second edition, with additions, in 1834 and 1835. Unlike some other Slovakian authors however, he was far from exhibiting a narrow and exclusive attachment to his native dialect. Considering the Slavonic prose a medium so well adapted to the dignity of literary composition, he took for the language of his writings the Bohemian, though it was at the time rejected for German in Bohemia itself by several of the same authors. In 1821 at Prague he published a volume of "Elegies on the Bosom" ("Basom" ("Poems"); and in 1824 at Buda, a new edition, under the title of "Sawye Doera" ("The Daughter of Glory"), The copy of the second edition, in the British Museum, formerly belonged to Tattersall, to whom it was presented by Safarik, and who has written "This Hitherto remarkable book, and how its tree and fiery spirit should have burst this Austrian censorship is altogether unintelligible to J. B." The leading idea of the poems is that of the common bond of union between all the Slavonic nations, approached by a sequence not looked upon with favour by the Hungarians, who were anxious to see their Magyar language extended over the whole of Hungary, and observed with apprehension that the Slovians to the north of the kingdom, and the Slavonians to the south, were beginning to become conscious of their relationship. Kollar proceeded more and more to develop his idea in his "Slaeva Bohynie" ("The Goddess Sia or Glory"; a collection of philological and mythological studies, in a work in German, on the connection between the Slavonic and Latin dialects, "Ueber die literarische Wechselbeziehung zwischen den Stammen und Mundarten der slavischen Nation" (Pest, 1831). In this publication the wish for a general combination of the Slavonic races, for the sake of a great amalgam, was expressed than in any previous one.

The same idea pervades the "Cestepis" (Pesth, 1843), a record of a journey to Upper Italy, the Tyrol, and Bavaria, made by Kollar in 1841, chiefly for the purpose of discovering traces of Slavonic antiquity.

Among his other productions is a volume of sermons, "Kame" (Pesth, 1831), which were found so eloquent that they were translated into several languages. Kollar was obliged to leave Pesth by the revolution of 1848, and must in the same year have seen many of his hopes destroyed by the breaking up of the Slavonic Congress at Prague by the cunning of Wende-schlagzelt. In the next year he was, probably by way of compensation, named professor of archaeology at the University of Vienna. In 1843 he made a journey to Mecklenburg, to study the ruins of the Obertors, and on his return to Vienna was surprised by death on the 29th of January 1852, when he was preparing for the press a German work, "Das slawische Altitalien," intended to prove the ancient inhabitants of Italy spoke a Slavonic language.

The work of Kollar which is chiefly admired by his admirers, is his "Slawy Doera," which in its latest shape, as it appears in his "Dils Benciaks" ("Poetical Works") published in 1827, comprises 940 stanzas, and extends to 638 sonnets, having little connexion except the common idea of the "Panalavism" which pervades them. Whatever the merit of some of the earlier portions, there is no doubt that some of the later editions are exactly calculated to awaken respect for the work; in particular some coarse attacks on Mr. Paget and Miss Paroos, apparently dictated by a feeling of resentment at their having spoken well of the Hungarians. The prose works of Kollar contain much information on the Saracens, and are disfigured by an occasional outbreak of the same spirit of mere Slavonic nationality. Several of Kollar's sonnets are translated in Sir John Bowring's work on the Bohemian poets.

KOLYFRIT. [MINERALS, S. 1.]
KOLN, or Cologne.

KONIYEH (Korneh, Koniah), a city in Asia Minor, capital of the pashalik of Karahan, which includes the greater part of Phrygia and Pamphylia, is situated in a wide plain in Lat. 38° 45' N, long. 32° 45' E, long. 305 miles E. by S. from Smyrna, and is 119 miles distant from the讥ithmetic Population, 30,000. The town is surrounded by walls built with well-cut blocks of stone, and strengthened by square towers, some of them richly ornamented with cornices, arches, and festoons, lion's heads at Pergamon, and in the north end. The walls rise from the brink of a wide fosse, and are pierced by handsome gateways, some of which are constructed with fragments of ancient structures. Within the city, when seen by Hamilton, presented little except ruin and decay; large spaces lay covered with heaps of dilapidated mosques and deserted houses. The modern town and the bazaars occupy the more eastern part of the site, where also is the konak, or house of the pasha. The houses are low, and mostly built of sun-dried bricks, and stand on an old castle, which is in the centre of the town, is crumbling, the stone facing having been removed to build the pasha's konak. Konyeyeh contains many beautiful remains of Saracen architecture, among which may be mentioned the mosque of Sultan Nabiyl with its immense mihrab, and the Kremi Minaray Djamii (Mosque with the Minaret reaching to the Stars), which is exquisitely adorned with delicate tracery, fretwork, and mouldings. The minarets are chiefly of glazed tiles and bricks of various colours, red and blue prevailing. The old Turkish prison which forms part of the old castle is an interesting half-ruined structure, bearing some resemblance to a gothic castle with its ruined towers, battlements, and keep. The pasha's konak is a large straggling building surrounded by walls approached by steps over an earthy ground, part of the site being now used as a cemetery. The other objects of note in the town are its large bazaars, several medressahs, or colleges, several sepulchral chapels, a few Armenian churches, the public baths and khans, and the tomb of a Moslem saint venerated all over Turkey. The manufactures are confined to carpets and blue and yellow marocco leather. Cotton, wool, and skins are sent to Smyrna.

The most interesting neighbourhood of the town is bordered by a broad belt of garden ground, with occasional groves of verdure by irrigation. The rest of the place in summer is a dusty desert; in winter flooded and impassable. The city is supplied with fruit and vegetables chiefly from the Greek village of Ziliach, which is two hours' distant, and situated on the way to the Saracen antiquity. This village is inhabited by about 5000 Greeks, descendants of the ancient inhabitants of Koneyh, who were driven out and obliged to settle here by the Turks when they captured the city.

Koneyh is the ancient Iconium, which Xenophon calls (Anab., i. 2) was in Phrygia; in later times it was considered the capital of Lycaonia. Under the Romans it seems to have risen in importance. Cicero spent ten days in Iconium on his way to Silicia ("Epist. ad Atticum," v. 30). In the first age of Christianity it is described as a populous city inhabited by Greeks and Jews. St. Paul and St. Barnabas preached in the synagogue of Iconium. Under the Greek emperors the city continued to be the metropolis of Lycaonia; but it was wrecked by them from first by the Saracens, and afterwards by the Seljuks Turks about a.d. 1075, who made it the capital of their dominions. Under the Seljuks, and during the period of the Crusades, Iconium acquired its greatest celebrity. The Seljuk dynasty was extinguished in 1354. After a period of anarchy the city was seized by Othman, the founder of the Ottoman empire in Asia, which had Brusa for its capital. From this time Koneyh declined rapidly. Ibrahim Pasha, commander of the Egyptian army, partly defeated the Turks near Koneyh, December 20, 1832.

A Christian synod held at Iconium about a.d. 330 pronounced against the validity of heretical baptism. Koneyh is looked upon by the Moslems as a sacred city; many diversions revolve in it, and it is visited by many pilgrims.

KOSTENDJE, or KÜSTENDJI, a sea-port town or rather village, in the Bessarabia, in Russia, is situated in the Dobrudjeha, at the eastern termination of the fortification called Trajan's Wall, 225 miles in a straight line nearly due north from Constantinople, and about 40 miles E. from Rassova. The town, which consists of about 500 houses, is built upon a bed of white limestone, on the summit of a large and singular projection of limestone rock, which rises precipitously from the sea to the height of about 100 feet, and shelters the harbour on the northern side. The harbour is exposed, except on the north side, and ill adapted to vessels lying in from the wind. Kostendje occupies the site of an ancient town, Constantiniana, which is said to have been founded and named from Constantine the Great. It retains in its ruined mole traces of Roman masonry. The town has some trade in corn. The project of opening a channel for the Danube across the Dobrudjeha by the chain of lakes called the Kara—Su into the harbour of Kostendje has been often mooted. [Donatzschau, S. 2.]

KÖTEN. [Görmev.] KOZLOFF. [Aquia.] KRAIN, or CARNIOLA, a crownland of the Austrian empire, is bounded N. by Carnia, E. by Styria and Croatia, S. by Croatia and the Kistendar, and W. by Friuli and the circle of Görz. The area is 3858 square miles, and the population is estimated at 1,062,603. Kriš (4562 feet) is the highest peak.

The surface is extremely rugged and mountainous. The principal chain of the Carnic Alps penetrates into the north-west of the crownland, where it terminates in the mass of Maksamov, and is separated from it by the valley of the Drava, 10,000 feet above the level of the sea. The northern boundary is formed by the offshoot or continuation of the Carnic Alps, which springs from the main chain near the village of Weisseneis in the north-western angle of the crownland, forming the watershed between the Drave and the Savar, and running in a general south-east direction between Carnithia and Carniols, through Croatia and Slavonia, where it terminates in the valley of the Danube. This range, which presents a very different appearance in its different parts, is studded with many isolated peaks, separated by basins, and divided by narrow ridges. It has a curious appearance to one who is not accustomed to the mountain scenery of the Alps. The sharp ridges and narrow valleys, the forests, and the great clefts and gorges, viewed from the middle of the basin, are so extraordinary and so grand that one is almost inclined to imagine oneself in some part of the Rocky Mountains or the Andes. The climate in the mountains and uplands is sharp; the summers are very warm; and snow disappears from the mountain tops only in the height of summer. The Bora, or north-east winds, at times sweeps the Karst and the more exposed parts of the country with furious violence. In the glacier and valley of the Savar, when the winter is over, the climate is much milder, and the vine, the chestnut, and maize flourish. Rye, barley, oats, some wheat, potatoes, pulse, flax, hops, and fruit are grown. In some parts the mountain slopes are clothed with pine, fir, and larch. The waters are of medium quality, and are thinned for the use of the smelting-furnaces. On the mountains many rare Alpine plants, medicinal herbs and roots are found. Horned cattle and horses are small; swine and poultry abound. Among the wild animals are deer, wild boar, the somara, the somach, the mountain hare, the racoon, and the hare. Birds of prey are numerous. Of game-fowl the principal kinds are pheasants, bustards, partridges, snipes, and water-fowl. Among the minerals the most important is iron, which is found in ironrich beds of various sizes, from microscopic to large blocks. The metals are iron, copper, zinc, lead, silver, and gold. The iron is found in gipsy deposits, and the copper in the mountains of Sorsa and Kranj. The iron is used in various forms, either as iron, copper, zinc, lead, silver, and gold. The iron is found in gipsy deposits, and the copper in the mountains of Sorsa and Kranj. The iron is used in various forms, either as iron, copper, zinc, lead, silver, and gold.
Adelberg under the name of Polk; this stream losses itself in the grotto of Adelberg and reappears in the Usn, which again sinks below the surface, but reappears at the village of Ober-Laybach, where it becomes navigable for boats. The remains of the Land of Carnikau, or Zirkuni, is noticed in a separate article.

The crownland is divided into 10 circles. With the exception of Laybach and Idria the towns are small. Laybach, or Laybach, the capital of the crownland, is situated in 48° 54' N. and 14° 29' E., is about 36 miles from Vienna by the Vienna-Trieste railway; in an extensive valley near the mouth of the navigable river Laybach, which divides the city into two parts, connected by five bridges; and has with its eight suburbs about 15,000 inhabitants. It is surrounded by the remains of ancient walls, churches, a lyceum, a gymnasium, and many other public institutions. The chief industrial products of Laybach are porcelain, linens, and refined sugar; there is an active transit-trade from the interior to Trieste, in which direction a railway is in course of construction. The citadel, situated on a commanding eminence, is now used as a prison. At a short distance to the north of the town there is a stone bridge of 11 arches, 540 paces in length, over the Save. Laybach, the residence of the prince, is celebrated for its beautiful scenery. Neumarkt, famous for the manufacture of syces, sickles, &c., none of these towns have so many as 2000 inhabitants.

Nestuditid, the capital of a circle, is beautifully situated on the river Gurk, 36 miles E.S.E. from Laybach. It is a very picturesque and pictoresque form. The town consists of between 400 and 500 houses, and has about 5000 inhabitants, who subsist partly by making and straw-plaiting; but the greater part are employed in the mines and works. A large building called Schloss, in the middle of the town, contains the office of the manager of the mines; close to it is the entrance to the mine by a large iron gate, which opens to a horizontal passage hewn in the solid rock, leading to a flight of 757 steps cut in the lime-stone rock, which are kept in perfect order. The history of the mines is connected with the history of the town. In this stair-case there is a small at the churchyard where the miners perform their devotions before they proceed into the mine, and where a couple of tapers burning on the altar help to cheer the glooms that reigns in these subterranean caverns. The whole town is defended by a garrison of 400 musketeers and 150 dragoons running in all directions, and would soon be bewildered in the labyrinth without a guide. This mine is one of the greatest curiosities in the Austrian empire, and unequalled for the order, beauty, and safety which are remarked in every part. The various exhalations of the quicksilver, which sensibly affect respiration, and the suffocating heat, soon make the visitor anxious to return to the light of day, to which he ascends by a perpendicular shaft in a kilometer which will not support the weight of a man. This is the last step from earth, at a great distance from the spot at which he entered. The greatest depth of the mine is 700 feet. About 100 tons of mercury are produced annually. The stamping-mills, washing-houses, furnaces, and roasting-houses for the refining of the mercurial ore are at a short distance below the town. Besides the quicksilver works there is a manufactory of cinnabar, which produces 1800 cwt. annually. In the vicinity there are marble, jasper, and freestone. All the establish here in the crownland, and there are various beneficent institutions for the poor miners, whose health is most dreadfully impaired by the deleterious atmosphere in which they ply their sily trade. These mines, the grottoes of Adelberg, and the Land of Carnikau, are the principal sources of the Carniola.

Carniola was, until the political arrangement of the Austrian empire in 1849, divided into the three circles of Laybach, Neustadid, and Adelberg, which corresponded with the older divisions of Upper, Lower, and Inner Carnia respectively, and formed the government of Laybach. Carnia was early inhabited by a people of Slavonic stock, and formed in the 10th century an independent margraviate, which at a later period the dukes of Austria and Carnia divided between them, and which was raised in the 12th century to a dukedom and the duchy of the Earl of Tyrol in 1335 fell to the Earl of Gurz, from whom it came, through failure of male issue, to the house of Austria in 1864. By the treaty of Vienna in 1810 Carnia was ceded to France, and in 1814 to Modena. In 1815 it again came into the possession of Austria, and formed part of the kingdom of Illyria. [ILLYRIA.]

Krasinski, Count Valerian, was a native of the ancient Polish province of White Russia, and was descended from a noble family. He embraced at an early period the Protestant faith, to which he adhered. He received a superior classical education, and while yet a young man was appointed chief of that department of the ministry of public instruction in the kingdom of Poland which was charged with the superintendence of the various classes of dissenters. He was zealous in his endeavours to promote instruction among them, and especially exerted himself in the establishment of a college at Warsaw for the education of such dissenters as were willing to pay the expense of valuable works, especially those on scientific subjects, he was the first to introduce stereotype printing into Poland, and this was not accomplished without a considerable outlay. In 1831 he published a number of pamphlets in Polish, while the revolutionary movement of 1830 had proclaimed the throne of Poland vacant, and organised a national government, with Prince Czartoryski as president, a diplomatic mission was sent to England, of which Count Valerian Krasinski was a member.

When the revolution began it seemed probable that the revolutionary movement of his countrymen, he was still in England, where he then became, with many others of his countrymen, a penniless exile. After having instructed himself in the English language, he attached himself to a merchant of some note who had a considerable number of valuable works. He resided in London during the first twenty years of his exile, and during the last five in Edinburgh, where he died December 22nd, 1855. He was a man of varied learning, and possessed extensive information, especially on all matters connected with the Slavonic races. His conversation was instructive and his manners elegant, and he was admitted to the best society.

His most important works are the following:—'The Rise, Progress, and Decline of the Reformation in Poland,' 3 vols. 8vo, 1839-40; 'Panaslawism and Germanism,' 12mo, London, 1848; 'Lectures on the Religious History of the Slavonic Nations,' 8vo, London, 1849; 'Sketch of the Religious History of the Serbs, Slovenes, Montenegrans, and the Slavonians in Turkey,' 8vo, Edinb. 1853; 'A Tractate on Relics, by J. Calvin, newly translated from the French Original, with an Introductory Dissertation on the Miraculous Images of the Roman Catholic and Russo-Greek Churches,' 8vo, London, 1850. His works and pamphlets on recent political subjects, especially on those connected with the restoration of Poland. [MINERALOGY, S. I.]

Kugler, Franz Theodor, Professor of the History of Art in the Royal Academy, Berlin, was born on the 19th of January 1808, at Stettin in Pomerania. On the completion of his college studies Herr Kugler especially devoted his attention to the early history of painting and architecture, both in the different periods which produced the ancient arts, and subsequently visited Italy. Poetry and music also occupied much of his attention, and he in 1830 gave evidence of his attainments in these arts by the publication of his 'Sketch Book,' in which he included original compositions in poetry, music, and linear drawing. His book 'The History of Painting from the Age of Constantine to the Present Time' appeared in 3 vols. in 1831. It was received with great approbation by his learned contemporaries and by students of art generally, and was quickly translated into the leading languages of Europe. In
England the translation appeared in parts, the 'Schools of Painting in Italy, translated by a Lady (Lady Eastlake), with the assistance of Mr. G. S. Scharf, and by B. B. Kugler, under the editorship of Sir Edmund Head. A second edition of the 'Handbuch' was issued in 1850, in which, with the assistance of Dr. B. Scharf, the work was brought to a greater extent remodelled, and a large amount of new materials embodied; and from this revised work a new edition of Sir Charles Eastlake's version of the 'Italian Schools' was published in 2 vols. 8vo, with additional notes and upwards of a hundred woodcuts, translated into English by A. Moriarty, under the title of 'History of Frederic the Great' (Lond. 1844); 'Beschreibung der Kunsthäuser von Berlin und Potsdam', a work of much more labour and research than its title would indicate; *Karl Friedrich Schinkel: eine Charakteristik seiner Kunstsammlungen* ('Schinkel: the Influence of his Theories of Art'), (Stuttg. 1842), a distinct work from the 'Handbuch der Geschichten der Malerei'. Both these works appeared at Stuttgart in 1848, where also was published (1845-62) a folio atlas of plates to illustrate his histories of art. For more than twenty years Dr. Kugler lectured in the University of Frederick William, as well as in the Royal Academy of Berlin; and also filled for some years an important position in the Ministry of Public Instruction. He died on March 16, 1868.

KUPPERSCHAUM. [MISCELLANY, S. 1.]

KUPPERSCHAUM. [MISCELLANY, S. 1.]

LABIUS, an island in the Malay Archipelago, and the seat of a British colonial government, is situated near the north-west coast of the island of Borneo, and 30 miles N. from the town of Borneo, in 6° 22' N. lat., 115° 10' E. long. The island is about 10 miles in length, 5 miles in breadth, and 25 miles in circumference. The population in 1886 was 2,500. The island is well supplied with good water, and contains coal. It was ceded to the British in 1846, and the colonial government was established on it at the beginning of October 1848.

The locality, on which the government establishment was formed consists of a narrow and slightly raised ridge on the sea-shore, forming the outer edge of a low flat, called the Plain, which is in many parts below the level of the sea, and was converted into a marsh during the rains. The area of the Plain probably does not exceed 100 acres. It is bounded on the inland side by swampy tracts of jungle. The harbour is tolerably good. The unhealthiness of the marshy ground in the Plain has been considerably abated in consequence of the construction of a canal, by which the water is carried off.

The coal is wrought on the north-east point of the island. The mines have been taken by the Eastern Archipelago Company, who in 1850 exported 6092 tons of coal, of which 3090 were shipped to Dutch East India, and 3002 to British navy. During 1852 there entered inwards 1198 ships and prahus, of an aggregate burden of 8233 tons; and there cleared outwards 27, of an aggregate burden of 5069 tons. The imports in 1852 were valued at 30,970l.; the exports at 16,060l.; the principal exports were:—Coal, 6482l.; sugar, 2879l.; bird-nests, 1973l.; pearls, 1600l., and camphor, 1629l. The principal item of revenue is the royalty on coal. Farm licences are increasing in value, improved rentals being obtained at each succeeding sale.

LACHMANN, KARL, professor in the University of Berlin, and member of the Academy of Sciences, occupied a high rank among the critics and philologists of Germany. He was born at Brunswick on the 4th of March 1793. In that town he received his early education, and under the teacher, Konrad Heusinger, was first awakened his love for literature. For one session, in 1809, he attended the lectures of Hermann in the University of Leipzig, and pursued his studies in that of Göttingen, where, in conjunction with Dissen, Shultze, and Bunsen, he founded a philological society in 1811. While at Göttingen, Benecke lectured upon the old German literature, which probably directed Lachmann's attention more particularly towards it, and at a later period led to much valuable criticism upon and editions of many of the early German writers. During the short war occasioned by Bonaparte's return from Elba to France in 1815, Lachmann served as a volunteer in the Prussian army, but continued till the end of that year. In 1816 his edition of Prochorus, which was published at Göttingen, was published at Leipzig; and at Easter of that year he read his probational essay before the University of Berlin, the draft of which was presented to the Academy of Sciences under the title of 'History of Frederic the Great' (Lond. 1844); 'Beschreibung der Kunsthäuser von Berlin und Potsdam', a work of much more labour and research than its title would indicate; *Karl Friedrich Schinkel: eine Charakteristik seiner Kunstsammlungen* ('Schinkel: the Influence of his Theories of Art'), (Stuttg. 1842), a distinct work from the 'Handbuch der Geschichten der Malerei'. Both these works appeared at Stuttgart in 1848, where also was published (1845-62) a folio atlas of plates to illustrate his histories of art. For more than twenty years Dr. Kugler lectured in the University of Frederick William, as well as in the Royal Academy of Berlin; and also filled for some years an important position in the Ministry of Public Instruction. He died on March 16, 1868.

LADING, BILL OF. By the statute 16 & 19 Vict. c. 112 of 1843, the Act of Parliament, which previously passed only the property in the goods, now transfers all the rights of suit and all the liabilities of the original contractors.
the system of the Abbé Lamennais, and to explain that it combined the advocacy of the interests of the Roman Catholic Church, and the defence of liberal opinions in connection with it; and to maintain that religion, so long neglected, and suffered to dwindle in the upper classes, ought to be, and might be regenerated by the concentration of public opinion demanded, in this paper, the complete separation of the spiritual from the temporal power, insisting that political influence ought to be transferred to the multitude by means of its franchise, composed of its own body, yet, instead of a change in the style of eloquence, somewhat biblical in form, and of remarkable power, produced upon an excitable people an effect so manifest as to provoke the censure of Rome, in the form of an encyclical letter, of the 16th of September 1833. Having been admitted to the Congregation of the Rota, he received a gracious letter of congratulation from the pontiff on the 29th of December. But in May 1834, the new champion of independence in church matters produced his most ambitious book, the‘Paroles d’un Croyant’, a pathetic lamentation, addressed alike to the suffering classes, and to the great and powerful; a work which rendered for ever the bond that united Lamennais to the see of Rome. Irritated by this new provocation, Gregory XVI, in a bull of 27th November 1834, attacked the book in very severe terms; whilst the revolutionary party applauded his advocate for his independent spirit and original powers of mind. This stigmatised by the Church, the Abbé was prosecuted for levelling accusations, and by the people hailed as an apostle, the Abbé Lamennais set out on his travels. He now produced in rapid succession: ‘Les Affaires de Rome’, in 1836; ‘Le Livre du Peuple’, in 1837; ‘Le Pays et le Gouvernement’, in 1840 (for which he was sentenced last and most earnestly ing), ‘Les lettres d’un citoyen’, in 1841; ‘Le Guide du Premier Age’, in 1844; ‘Une Voix de Prison’, in 1846; and ‘Les Conseils de l’Abbé Lamennais au Peuple’, in 1849. His most elaborate work, ‘Esquisse d’une Philosophie’, was published in 4 vols, 1840-44. He died February 17, 1854, unrecalled by his country, though during his last illness the most strenuous efforts were made to induce him to retract his heterodox opinions. By his express desire he was interred without any religious ceremony. It was one of his last and most earnest ingents, ‘to cast the papers, which contained his latest sentiments, should be published without alteration or suppression; but the religious advisers of his niece (who was also his housekeeper) so far wrought on her susceptibility as to cause her to refuse to give up the papers to the persons whom Lamennais had authorised to superintend their publication. The matter was in consequence brought before the proper legal tribunal, when the judges directed (August 1856) that the papers should be handed over for publication with their integrity. LAMPETER, Cardiganshire, a market-town, municipal and parliamentary borough, and the seat of a Poor-Law Union, in the parish of Lampeter-Port-Stephen, is situated in 52° 7’ N. lat., 4° 3’ W. long., distant 29 miles E. by N. from Cardigan, and 3 miles W. S. W. from Lampeter, the ancient seat of the Talley family, whose barons became privy councillors. In 1584 he visited Rome, met with the most flattering reception from Pope Leo XII, but declined the offer of the Cardinal’s hat, made to him by that pontiff. His next work, ‘La Religion considérée dans ses Rapports avec l’Ordre Général de l’Église Politique,’ began to exhibit that freedom of thought, reaching to the last boundary of revolution (but which, however, independent of church interests, abandons nothing in spiritual faith), for which he subsequently became so widely known. For this book he was summoned to appear before the Cour Correctionnelle, and condemned to a fine.

The general agitation and the ferment in the public mind, which preceded the fall of Charles X., had gradually produced a modification in the opinions of this enthusiast, whose faith was too sincere to be stagnant; the revolution of July induced him to adopt the principle of the people’s supremacy. Still he continued the same full believer, and earnest worshipper in the Church of England, and his last book is yet another volley of cannon-shot from the Roman Catholic Church. In attaching himself with equal warmth to the democratic principles, he pointed his objections at the temporal abuses of the Church; whilst his reverence for her spiritual authority remained unshaken. In September 1834, he was elected a member of the Church of London, in which several young men who had adopted his opinions, assisted him with their contributions. Among these were the Abbé Gerbet, the eloquent preacher Lacordaire, and M. de Moulême. The object of this journal was to spread

LAMENNAIS, FELICITE-ROBERT, ABBE DE, the son of a ship-owner of Saint-Malo, was born at that port, on the 14th of July 1787, the year of the universal jubilee. He was educated at the Congregational school at Saint-Malo, and then, at the age of 13 years old. In 1794, having been sent to live with an uncle, this relation not knowing what to do with a wildfowl boy, used to shut him up for whole days in a library, consisting of two compartments, one of which, called ‘Hell,’ contained a large number of prohibited books, which little Robert was enjoined not to read. But the lad already cared for none but books of reflection, and finding some of these on the prohibited shelves, that division became his favourite. Long hours were thus spent in reading the ardent pages of Rousseau, the theorist of man, and it was in this manner that his bent in sentiment and philosophy. Such a course of reading, far from producing its usual effects of precocious vanity and unbelief on so young a mind, served rather to ripen his judg-

LAMETE, a town and a market, in the county of Cardiganshire, and the diocese of St. David’s.

LAMPETER-PoRT-STEPHEN, a parish, in the union of Lampeter, in the hundred of Trefin Down, and in the county of Cardiganshire; 6 miles W. S. W. of Lampeter, and 4 miles N. E. of Cardigan. It contains 6235 acres, of which 1500 are arable, 3000 meadow and pasture, and 300 wood. The population is 1872. The living is a vicarage in the archdeaconry of Cardigan and diocese of St. David’s. The poor are served by a parochial school, with a master, and 20 pupils. There are 2 Poor Law unions, containing 2 parishes and townships, with an area of 74,200 acres, and a population of 1801 of 9883.

The town is pleasantly situated on the left bank of the river Teify, and 5 miles from the town of Lampeter-Port-Stephen. It was so called from the Teify Down. Besides the parish church, which was rebuilt in 1836, there are places of worship for Wesleyan and Calvinistic Methodists and Independents. A National school, and a Free Grammar school. An agricultural society has been established here. A county court is held. The market day is Wednesday, and there are 11 fairs in the course of the year. St. David’s College, Lampeter, founded in 1823 by Bishop Burgess, was incorporated in 1832, and received by a supplementary act of 1846, authorising the university to grant the degree of Bachelor in Divinity. The course of instruction is especially for Welsh students, but others are admitted. The college grants at the end of the term a certificate to students who have satisfactorily completed their theological course; at the end of three years the degree of Bachelor in Divinity. The course of instruction is especially for insiders, but others are admitted. About 30 scholarships and exhibitions are attached to the college, and it possesses a library of 30,000 volumes. The college buildings, erected in 1827 from a design by G. R. Cockell, R.A., stand on an
elevated site near the town, and form a quadrangle of a picturesque appearance: they accommodate about 70 students: the number of students in 1801 was 50. The annual income of the college is about 3000l.

LAMPRIS, a genus of Fishes belonging to the family Somersidae. It has an oval body greatly compressed; small mouth and rounded and pointed teeth. The dorsal fin of sides of the tail carinated; teeth wanting; branchiostegal rays 7.

L. guatatus, the Opah, or King-Fish, has been taken on this coast of the Bay of Biscay, is a rare fish, and as beautiful as rare. The upper part of the back and sides are of a rich green, reflecting both purple and gold in different lights, passing into yellowish-green below; above and beneath the lateral line are various round yellowish-white spots, from which the name of Opah is derived. Red, orange, and scarlet; all the fins bright vermilion. It has been remarked, on account of these showy colours, that the Opah looks like one of Neptune’s lords dressed for a court-day.

This fish was formerly called Z. Luna and Z. imperialis.

LAND-CRAB. [OSCARINUS.]

Launceston, with its fine bridges, has been associated with the Royal Academy, was born in London in 1769. He learnt engraving under Byrne, a landscape-engraver of much ability; as early as 1793 he acquired some celebrity by engraving some vignettes, after Lutterbourg, for Maciule’s Bible; and increased his reputation by engraving the ‘History of England’ and ‘Moore’s Views in Scotland.’ Mr. Landseer also published an excellent series of engravings of animals from the works of Rubens, Snyders, Gillpin, and other eminent artists. Mr. Landseer delivered a course of lectures on engraving at the Royal Institution, which were published in the following year, and excited some discussion in the profession on account of some peculiar views promulgated in them. In the same year he was elected an Associate Engraver in the Royal Academy, and in 1800 a member; but the position assigned to engravers in the Academy—they not being admitted under any circumstances into full membership—was the source of considerable ill-feeling among engravers, and the post of associate engraver had been refused by several eminent engravers when Mr. Landseer accepted it. He announced however that he had only done so in the hope of being able to labour at a greater advantage in striving to remove the obnoxious restriction. Accordingly he memorialised the president and council on the subject, but after a year or two of correspondence and controversy the claim was rejected. Landseer’s mortification is said to have been so great as to have disgusted him in a great measure with his profession, and for some time after this he so appears, not from this time to have ever carved comparatively little. The literary taste however which lecturing and controversy had aroused, seems to have cultivated. Delighting in controv-

LARCENY. Petty larcenies may now be tried and summarily determined, with the consent of the accused person, by magistrates in petty sessions, the punishment in such cases being usually a fine, or, when the offender be a servant, a discharge, or, in cases of fraud or malicious injury, imprisonment not exceeding three months (10 & 11 Vict. c. 89; 19 & 11 Vict. c. 37; 18 & 19 Vict. c. 126). Persons confessing such offences may under the last named statute be similarly punished by the same tri-

LARIZZABALACEAE, Larrizabalaceous, a small natural order of Plants, containing 7 genera and 15 species. The species are twining smooth shrubs with alternate compound leaves, solitary or clustered; flowers coloured white, lilac, purple, or deep yellow, sometimes fragrant. The sepals of the male plant are 3 or 6 in 2 rows, deciduous; petals 6 in 3 rows Opposite the sepals, the inner ones smaller, or gland-like, or absent. Stamina 6, opposite the petals; filaments united into a tube, or even distinct; anthers turned outwards, rarely inwards, 2-celled, opening by a longitudinal slit. The female flowers as before, but larger, with 8 very imperfect stamens. Carpels distinct, or united, 3; ovary superior, 3-fruited, simple or single stigma. Two of the genera inhabit the cooler parts of South America; the remainder are from the temperate parts of China. Buranae is the only tropical form. These plants appear to be harmless. Some of them are eaten by the natives of Java.

LARKSPUR. [DELPHINIUM.]

LARNE, county of Antrim, Ireland, a sea-port town and the seat of a Poor-Law Union, is situated in a sheltered bay accessible by good roads and rail. It is distant 14 miles N.N.E. from Belfast, in 54° 50' N. lat., 6° 50' W. long. The population in 1851 was 2728, besides 846 in public institutions. The town is governed by nine commissioners. Larne Poor-Law Union comprises 13 electoral divisions, with an area of 37,721 acres, and a population of 34,710. The town originally sprang up under the protection of Oldrefter Castle, which was erected in the reign of Henry III., upon a little headland close to the town, where its ruins are still seen. In the older parts of the town the streets are narrow, crooked, and ill-paved, and the houses very inferior; the modern part consists chiefly of one long wide street of well-built houses. The places of worship are the parish church, three Presbyterian meeting-houses, a Roman Catholic chapel, and a Methodist chapel. Cotton-cloth, sail-cloth, ropes, and leather are manufactured; and there are several bleach-nills and flour-mills. The bay forms a good natural harbour for small vessels. Lime is exported in large quantities from the extensive lime-pits which are to be seen in the vicinity of the town. The other exports consist chiefly of provisions. Larne is now a mere out-port of Belfast. Fairs are held on July 31st and December 1st. The town has a dispensary and a petty sessions court.

LARNE. [MINERALOGY. S. 1.]

LAUDER, Berwickshire, Scotland, a royal and parlia-

LAUDER, Berwickshire, Scotland, a royal and parliamentary burgh in the parish of Lauder, is situated in 55° 42' N. lat., 2° 40' W. long., 264 miles S.E. from Edinburgh. The population of the burgh in 1851 was 1105. The town is governed by a chief magistracy and 17 councillors; and unites with North Berwick, Dunbar, Haddington, and Jedburgh in returning one member to the Imperial Parliament.

There is only one street in the town. The parish church, the town hall, and three taverns of the name of 'King,' are here. The Free church, and the United Presbyterian church are the public buildings. The burgh possesses an extensive common, which is exclusively used by a small body of privileged burgesses. Close by the town is the residence of the Earl of Lauderdale, Thirlestane Castle, which stands a mile from the town. The other public documents and other matters of importance are published in early life two novels, 'Lochandu,' and 'The Wofes of Badenoch.' His paper on 'The Parallel Roads of Glenroy,' which was read before the Royal Society of Edinburgh,
and published in vol. ix. of their 'Transactions,' consists of a description of the geological strata of that district of the Highlands of Scotland. In 1830 Sir T. D. Launder published an Account of the Great Floods of August 1829, in the Province of Morys and the adjoining Districts, 5vo, Edinburgh. In 1837 he published 'Highland Rambles, with Long Tosses to shorten the Way,' 2 vols 8vo, Edinburgh, and in 1841 'Legendary Tales of the Highlands,' 3 vols. 12mo. He was long a member of the well-grounded, and a 'Memorial of the Royal Progress in Scotland' in 1844, 4to, Edinb., 1843. For the 'Edinburgh Tales,' conducted by Mrs. Johnstone, 3 vols. Edinb., 1845-46, he wrote the story of 'Farquharson of Inverey,' and 'Donald Lamont, the Braemar Tartar.' He was Fellow of the University of Oxford, and had issue two sons and seven daughters. He died May 29, 1848, at his residence, the Grange, near Edinburgh, and was succeeded by his son, Sir John Dick Lauder, who was born in 1813, and married in 1845. Sir T. D. Lauder was deputy lieutenant of the counties of Haddington and Elgin, and a Fellow of the Royal Society.

LAW, CRIMINAL. Upwards of 65,000l. has been spent on various commissions, which have been issued during the last year, in the consolidation or codification of the criminal law; but this work has not been attempted, nor have any really practical measures been adopted for such an annual revision of our statutes as would in a few years naturally produce their consolidation, if not a codification of the whole system. One of two points only need be referred to. The summary jurisdiction recently conferred on magistrates in petty sessions is noticed under Launcy, S. 2.; the liability of trustees to prosecution for breach of trust is of late common, and the measures that are effectuated in the course of the courts which take cognizance of crimes by the statute 14 & 15 Vict. c. 100, which abolished all technical objections for misnomers or nondescriptions, and invested the judges with ample powers of amendment. Finally, transportation as a punishment to be ordered by the court has been abolished by the statute 30 & 31 Vict. c. 3. Penal Servitude, as it is termed, created by statute 16 & 17 Vict. c. 99, has been substituted; but criminals sentenced to long terms of penal servitude confined at the expense of the country.

LECHLAD. [Gloucestershire.]

LEE, REV. SAMUEL, D.D., was born May 14, 1783, at Longnor, a village in Shropshire, about eighteen miles from Shrewsbury. He received the rudiments of education at a chartered school in that village, where at the age of twelve years he was apprenticed to a carpenter and joiner. At the age of seventeen he formed a determination to learn the Latin language, and though he had at first only six shillings a week, and afterwards seven, to subsist on, he contrived to buy rudimentary books and then classical writers, and by the end of his apprenticeship had accomplished his purpose. He then determined to learn the Greek, and this he also accomplished. The Hebrew, Chaldaic, and Syriac languages were next mastered. When in his twenty-first year, his reputation in Westminster was so great as to cause on the part of his employer the repairing of a large house, in which however a fire broke out, when he lost all his tools, and was reduced to extreme poverty. In the meantime the Rev. Archdeacon Coxe had forgotten him, and the Rev. Mr. Lockett lent him books, and assisted him in pronunciation. In the course of a few months he acquired the Arabic and Persian languages, and afterwards a tolerable knowledge of French, German, and Italian. For two or three years previously to 1813 Mr. Lee held the mastership of Bowerion's foundation school in Shrewsbury. In 1813 he left Shrewsbury, and obtained an engagement with the Church Missionary Society. In the same year he entered himself of Queen's College, Cambridge, and in 1816 took his degree of B.A. Having received ordination, he preached in the Church Missionary Society at Shrewsbury a sermon in aid of the funds of the Shropshire Auxiliary Bible Society. On the 11th of March 1819 Mr. Lee was elected Arabic Professor of the University of Cambridge, and in 1820 he was at Cambridge the time requisite for taking his d-gree of M.A. (which was necessary before he took the chair), a grace passed the senate to request the Prince-Regent to grant a mandamus, which was obtained accordingly. In 1829 the Professorship of Arabic, one of the six chairs, was abolished, and Mr. Lee was appointed to the chair by the King in Council. He was re-elected in 1833, and in 1834 took the degree of D.D. In 1833 he was appointed chaplain to the jail at Cambridge, and in 1835 was presented to the rectory of Bilton with Howarrogate. He took the degree of D.D. in 1827, and in 1831 was elected Regius Professor of Hebrew to the University of Cambridge, and with it obtained the accompanying canonry in the cathedral of Bristol. The degree of D.D. was conferred upon him by the University of Cambridge in 1833. He was afterwards presented to the rectory of Barley in Hertfordshire. He died on the 9th of December, 1859, at Barley rectory. He was twice married. Among the more important of Dr. Lee's works are the following:—'Hebrew Grammar,' 1830; 'Travels of Juba. Translated from the Arabic,' 1830; 'The Book of Job, translated from the Hebrew, with an Enquiry into the Nature, Progress, and End of Prophecy,' 1840; 'An Inquiry into the Nature, Progress, and End of Prophecy,' 5vo, Cambridge, 1849; 'The Events and Times of the Visions of Daniel and Ezekiel,' 1847. Dr. Lee, John, in 'The Hermit's Tale,' a poem; in 1796 'Almeyda, Queen of Granada,' a tragedy, which was successfully performed, Mrs. Siddons sustaining the principal character. In 1804 was published in six volumes, a novel entitled 'The Life of a Lover,' which is said to have been her earliest production, the effort of her girlish years, and is certainly one of the weakest of her writings. Her last work was a comedy, performed at Drury Lane Theatre in 1804, called 'Aspinwall,' which was condemned at Covent Garden. In 1805 she produced 'The Veil.' Her chief claim to notice, like that of her sister, rests on the 'Canterbury Tales,' of which she furnished two, 'The Young Lady's Tale,' and 'The Clergyman's Tale,' which occupy a volume and a half of the five volumes to which the series extended; and she wrote the introduction to the whole. These tales are certainly superior to her novels, but they are not equal on the whole to those of her sister.

Harriet's first appearance as an author was in 1795, when 'The Erroneous Lady's Tale' was published; this was followed in 1787 by a comedy, 'The New Peegree; or, Our Eyes may deceive us,' 'Clara Lennox,' a novel in two volumes, in 1797, and 'The Mysterious Marriage, or the Heirship of Rosalia,' a play, in 1798; all of which were forgotten at Covent Garden. In 1799 appeared her most successful novels, the first two volumes, the fifth and last in 1805; they were so immediately popular that second editions of the first two volumes were published in 1799. They consist of twelve tales, of which one, 'The German Tale—Krutirms,' furnished Lord Byron with the theme and some of
LEE 354

an al fins opposite and near the tail; pectoral fins large, descending to the inferior surface of the body, and by an extension of the membrane surrounding an oval disc; ventral fins indistinctly cleft. The body is elongated, the females are much more so than the males, the males contain the most definitely drawn characters, and a well-developed plug. Several of the other tales however show a considerable knowledge of the human mind, are unexceptionable in their reasoning, and are narrated in a simple and unaffected style.

LEERSIA, a genus of Grasses belonging to the tribe 

Oryzae. It has 2 pale compressed, keeled, and awnsless, the lower one much broader; stigmas protruding from the side of the pale, enclosed in the pale.

L. orizoides has a patent pale with many branches, spikelets triandrous, half oval, ciliated on the back. It is a creeping plant with a stem one to two feet high, never proembolus, and rooting at the joints. The leaves are broad and long-edge, with a yellowish, almost horizontal pale, in a tuft; pale rachis with a glaucous chin; pale, rarely, if ever, protruding in this country, mostly inclosed in the sheath of the uppermost leaf. It is found in marshy ditches in Sussex and Hampshire.

LEWIS, B.A. LEWIS, C.R. LEICETER, S. C. R. LEOCOATOM [Ceroloxa, s. 3.]

LEIXLIP, county of Kildare, Ireland, a small town finely situated at the junction of the Evey with the Liffey; 11 miles W. from Dublin, by road and railway from Dublin to Galway; part of the great route of Liffey and Bridgend. The parish church is in the pointed gothic style. The Roman Catholites have a chapel. The Liffey is here crossed by a bridge. Above the town is Leixlip, castle, built by Adam de Hereford, one of the Strangews's followers. A little way beyond the castle is the Liffey, a fine cascade, called the Salmon Leap. The town is a place of resort on account of the beautiful scenery near it. Fairs are held in May, July, and October.

LENEX, JOHN. Architectural engraver, was born in 1784, in Sun-street, Bishopsgate, London, where his father was a manufacturer of pewter; and to him the youth was in the first instance apprenticed, but disliking the business, he was at the age of seventeen transferred as a pupil to Mr. James Baire, an eminent architectural engraver, and remained with him four years. Le Keux formed for himself, however, a true and bolder style than that of his master, and eventually in the engraving of gothic architecture attained an excellence equalled by few in the profession. Indeed, it was here seen, that the gothic architecture was for the first time thoroughly well engraved in this country by him; and that his engravings did much to render the study of gothic architecture popular. He possessed a very constant and discriminating eye for the beauties both of the form and the details of gothic architecture, and consequently his engravings displayed, not only minute correctness, but that "feeling," as artists term it, which is always an evidence that the work is executed as a matter of enjoyment, and not merely as a task. Le Keux was in fact an artist and not a mechanic, and even the admirable architectural drawings of Mackenzie lost nothing in fidelity, and sometimes, perhaps, gained a little in spirit, under the rendering of Le Keux's born. The first important work we believe on which Le Keux was engaged was "Britton's Architectural Antiquities of England," and he also engraved much of "Britton's Cathedral Antiquities," and other of Mr. Britton's works; the elder Puqis's "Architectural Antiquities of Normandy," "Gothic Examples," and "Gothic Specimens;" and "Neale's Westminster Abbey," and "Churches (vol. 1.);" "The Oxford Almanac;" and lately the "Memorials of Oxford," and "Memorials of Cambridge," both of which were projected by himself and executed with much elegance, though of course from their smaller size with somewhat less freedom than the larger works. Mr. Le Keux died April 2, 1846. His eldest son, J. H. Le Keux, has a high reputation as an architectural engraver.

LEMA. LEV. LENZINITE [Minerology.] S. 1.

LEPIDOGASTRIDE, a genus of fishes belonging to the Superfamily Gobiidae, and to the family Cyclopteridae, or Discobolidae. [Discobolus, s. 1.] The genus Lepidogaster, is distinguished by its smooth body without scales; dorsal and anal fins opposite and near the tail; pectoral fins large, descending to the inferior surface of the body, and by an extension of the membrane surrounding an oval disc; ventral fins indistinctly cleft. The body is elongated, the females are much more so than the males, the males contains the most definitely drawn characters, and a well-developed plug. Several of the other tales however show a considerable knowledge of the human mind, are unexceptionable in their reasoning, and are narrated in a simple and unaffected style.

L. cornubianus, the Cornish Sucker, Juria Sucker, and Ocellated Sucker, Cyclopterus Lepidogaster of Pennant and C. Brandt's Abalone of Pantin are occasionally met with off the coasts, and has been taken on the coasts of Antrim and Clare in Ireland. This fish is small, a specimen described by Mr. Couch not being more than two inches and a half in length. It adheres with its sucker to almost any substance presented to it, and even to the human palpe. The general tint of the fish is a pale flesh-colour, with spots and patches of carminie about the upper and under surface of the jaws, around the eyes, on the top of the head, sides of the body, and abdomen.

L. bicarinatus, the Bicarinated Sucker, is a second British species. This fish is rarer than the last. It has been taken on the southern coasts of Great Britain. It seldom exceeds three-quarters of an inch to an inch in length. Its general colour is a very minute red; pale flesh-colour underneath, with a light-coloured patch between the eyes, and otherwise liable to some variation in the markings: the two spots on the sides not always very obvious. It lives in deeper water than the last species.

LEPIDOLOTHUS, a genus of Fishes belonging to the family Gadidae. It is closely related to the genus Mennis, to which the Common Cod belongs. The subfuscus are united with the nasal bone, and form a depressed muzzle, the latter narrowed above and below. The head and body have hard spines; the ventra are a little on the throat; the pectoral of less size; the first dorsal high; the second dorsal, anal, and caudal united; the jaws short; the teeth fine and short. The species inhabits deep water, and is not seen except when taken out of the water. Two species are known. They inhabit the Mediterranean and Atlantic.

LEPIDOLITE. [Mica, s. 2.]

LEPIODOTILE. [Mica, s. 2.]

LEPIODOTILUS. Detached, detached cones which are scattered through the various strata of the Coal Formation have been thus named. They are obviously organs of fructification, and have therefore belonged to some of the arborescent plants whose remains they accompany, a group of them as are preserved in the nodules of iron-stone, or are otherwise mineralised without pressure, alone offer the means of ascertaining to what existing families of plants they are most nearly allied; for in those that are crushed flat in the shale the remains of the plant are necessarily lost. This fact has led to the better-preserved specimens having been sliced, polished, and examined with the greatest care; but this expensive operation has hitherto thrown little light upon the true nature of the object. It has been suggested by the late Mr. Banks that certain conditions necessary for their complete illustration have never been di-played by one specimen, but the most important point, the nature of the organs of fructification, has hitherto wholly escaped observation in all. Every one being as an aggregate of organs of some kind, is necessarily to ascertain, not only the arrangement of these organs, but the nature of the tissues composing them, and their contents, before satisfactory conclusions can be drawn as to their relationship to any of the vegetable remains they accompany, or to whatever existing order of plants they are allied. The three necessary conditions are these:—

1. The arrangement of the individual organs of fructification, of which the cone is an aggregation, and the nature of the scales supporting them. These are characters sometimes displayed on the fracture of the specimen by ordinary means, though rarely, from the parts appearing to have suffered partial decay previous to or during petrifaction. The imbricating apices of the scales, which lie over one another like the petals of a pincushion, usually removed with the matrix whereas the fossil is embedded.

2. The tissues, or anatomical structure of the various organs composing the cone: namely, of the central axis, which is a central cylinder of the same form as the cone, and a narrow ring of the tube being inserted into the axis support the individual male or female organs; and of the latter themselves. These tissues can only be displayed by slicing fossils in the very best state of preservation, and in such as are changed into a more or less transparent mineral. Specimens of this description are exceedingly rare.
3. The two preceding considerations are secondary to the remaining one—the nature of the contents of the cones. There may be stamens or male organs—ovaria or female ones—or, lastly, capsules containing reproductive spores (which are peculiar to plants having no sexual system); for these three kinds of organs all occur arranged in the form of cones, indistinguishable from one another by any external marks. Up to the present time no carboniferous fossil cone has ever been known to supply this great desideratum, without which we must regard the materials as secondary fragments. But including these various objects are clusters of flowers or fruits, or are the spore-bearing organs of flowerless vegetables, as mentioned above.

Several species of Lepidostrobi are mostly found in seams or nodules of clay iron-stone, and are very highly mineralised, sometimes containing crystals of iron, and the cavities in their substance being filled with white carbonate of lime and magnesia. Those which are most complete always form the nuclei to nodules of iron-stone, and are therefore separately preserved; all in which the spores are preserved, have occurred as broken frustules within stems of Lepidodendron elegans and other species of that genus. Usually the fragments of Lepidostrobi are not more than half an inch long, and very frequently are mere discs; so that though there is often the appearance of several inches long, and traversing the whole length of the fragment of Lepidodendron, it will generally be found that this is owing to being placed each at an extremity of the truncheon, and opposite to one another. [See Figure, Lepidodendron.]

The absence of the fruit is, indeed, doubted, for no modern cone of any natural order could be broken up into the shallow discs which many of these fossils present. It is difficult to account for the presence of these fragments of Lepidodendron, unless we can but conjecture that the trunks of the latter were erect stumps, whose interior was hollowed out by decay—that these stumps were covered with water in which were fragments of Lepidostrobi and other vegetable matter, which were thus washed into the stumps. This supposition is founded on the following considerations:

1. The stumps of Lepidodendron appear to have been rooted and erect, and to have received the cone fragments into their cavities as fern fronds find their way into the axis of Sigillaria. When the stumps were preserved, and the stems it is evident that cones would have lain horizontally in them, and that no washing or drifting could have induced the fragments of these cones to lie with their axes parallel to them, or could have introduced so many into one trunk; and the latter would certainly have been materially compressed had they received on one side the pressure of the superincumbent shales.

2. Any stumps which might have been submerged and the fragments of the cones carried away from the water. Had the cones fallen from an overhanging forest they would have alighted in all manner of irregular positions, and in some cases overlain one another, which is never the case.

3. The deposition of the cone fragments is effected by the great rapidity of the water, and not by a sudden rush or current. This again is proved by the non-interference of the cones, and their uniformly vertical position with respect to the Lepidodendron.

It is hard to account for the accession of so large a volume of water as would submerge these stumps and deposit these fragments, and yet exhibit no signs of drifting in its course. The sudden fall of a tropical torrent of rain on a Lepidodendron forest, in which were hollow stumps of these trees, must have produced a deep ravine, and the Lepidostrobi from the trees and float up the fragments on the ground, depositing them together in the stumps. Another effect of such a fall would be to break down some of the older trees whose descending stumps would be prepared to incline other Lepidostrobi on the precipitation of the next similar torrent.

The extreme fragility of the Lepidostrobi displayed by these specimens is very satisfactory, as the Lepidodendron, which supplies the characteristic of this, which is eminently favourable to a rapid decomposition and intimate union with the silt or mud which is the basis of the clay-ironstone in the one case, and the formation of a homogeneous bed of vegetable matter, such as occurs in another; the abundance of the fragments too suggests a most vigorous vegetation, for they must indeed have been profusely scattered to be deposited in such numbers within narrow cylinders into which no current appears to have been directed.

It is worthy of remark that no fern-leaves are contained in any of these Lepidodendron stems; and their absence is more singular from their being commonly deposited along with branches of Calamites &c, in the erect stumps of Sigillaria resting on the coal-shales. This is no doubt connected with the well-known fact of the Sigillaria stumps being filled with sandstone, or the same material resting on the stumps about through which they root into; whilst the fossil Lepidodendron of the clay-iron-stone seams is of the same mineral as that wherein it is embedded. Were the fragments of Lepidostrobi washed into their inclining stumps by any current, that agent would in all probability have transported the remains of other plants to the same spot. The perfect preservation in which these fragments occur must be attributed to the protection afforded them by the surrounding Lepidodendron bark. That the circumference of the latter has been subjected to pressure may be inferred from the flattening of the prominences to which the leaves were attached. This pressure was moreover very considerable, as may be proved by comparing the evenness of their surface with that of a piece of Lepidodendron bark fossilised without pressure, and imbedded within the stem along with the Lepidostrobi.

If these cones be examined with reference to the known contemporaneous fossils which accompany them, it will appear impossible to deny their having the reproductive organs of the Lepidodendron. The fragments of Lepidostrobi, and the arrangement of the tissues in the axis of the cone entirely accords with that of the stem of Lepidodendron. Just as we find in modern Cycadaceae the temporary closure or extinction of the apical continuation of the branch, which bears leaves modified into organs adapted to support and protect the parts of fructification. The most positive evidence that can be adduced of Lepidostrobi belonging to a genus allied to Lycopodiaceae, and is afforded by the spores, the presence of which not only removes them from Cycadea, Conifera, or any other order of flowering plants, but directly refers them to the family of Lycopodiaceae. It is well known to botanists not only that these are far more peculiar to one natural order of plants, but that the spore diagram is no indicator of their contents or of the affinities of the plants which produced them.

Accordingly we find that Dr. Lindley, the first English observer who published any extended views on the affinities of these plants, states the probability of their being referrible either to Coniferae, Lycopodiaceae, or more probably still to Cycadea. Dr. Hooker, after describing the nature of spurious cones which have no relation to the reproductive organs of the plant, as in the common cone-bearing willow, wherein the cone is produced by the bud of an insect, as in a genus inhabiting Tierra del Fuego, where a cone is formed by this means from a leaf, says:—"Some of the so-called Lepidostrobi may be of this nature; witness the fact of wind-blown sandstone indicating whether it be a Lepidodendron or the apex of a branch crowded with short leaves. Were the Fuegan plant to occur in a fossil state the probability is, that its cones would be regarded as undoubted reproductive organs, and the plants themselves be referred to Conifera."

LEPTURUS, a genus of Grasses having solitary spikelets, imbedded alternately on opposite sides of the rachis of 1 inch in length, and a superior rudiment. The rachis is long, rough, cartilaginous, covering the flower. Fleshy scarios. Stigma feathery.

L. incurvatus has a cylindrical subulate spike; 2 glumes equaling or slightly longer than the lemma; stem from 2 inches to 6 inches in length; curved when dry; a variety of this species, L. fitiformis, the spikes are much more slender, filiform, scarcely at all curved. It grows in sandy salt-marshes.

[LENI.E. THE NORTHERN CRISTAGRAMA.] The following is Dr. Baird's arrangement of the British species of the Lernaeodae, or Lernaeas:

Tribe I. Anchoritaceae. Females—Attached to their prey by means of their foot-jaws, which are stout and armed with strong hooks. One pair of antennae; generally very distinct. Thoracic feet

2 2 3
nearly rudimentary, or represented by appendages of considerable size, but differing in form from ordinary feet.

Males.—Free and unattached; very small, and differing totally in appearance from the females.

Family Chondracanthidae.

Organs representing thoracic feet, in form of considerable-sized, cartilaginous-looking, not articulated appendages; generally three pairs in number. Three pairs of foot-jaws.

Genus 1.—Chondracanthus.

Two pairs of foot-jaws prehensile, the third nearly rudimentary. Appendages of thorax representing the feet, in form of claws, but not articulated, and not setiferous lobes or tubercles. Oviferous tubes very short, broad, and flattened.

C. Zei. Body short, and rather thick. Head rounded; antennae short, and rather broad; neck narrow, short. Thorax carrying on the under surface two pairs of small appendages, each consisting of three divisions or fingers, and furnished laterally with three pairs of longer prolongations, of many divisions, the terminal one on each side larger than the others, and bearing the oviferous sacs; the upper, and of the thorax is covered with short, conical, sharp-pointed spines. Abdomen rudimentary. Oviferous sacs flattened, containing many small ova.

It is found adhering to the gills of the Zeus faber.

Genus 2.—Lernomena.

Foot-jaws and thoracic appendages as in Chondracanthus. Oviferous tubes long, either club-shaped and stout or slender and twining.

1. L. cornuta. Female.—Head oval, rather elongated; antennae flattened, of considerable size, and projecting. Thorax elongated, club-shaped; anterior portion narrow for about a third of its length, the other two-thirds much broader, and terminating posteriorly in two sharp lateral tubercles of moderate length, and a middle one representing the abdomen, which is nearly quite rudimentary. Two pairs only of thoracic appendages are visible, occurring at the upper portion of the narrow part, each divided into two digits, at a slight distance from each other and from the side of the body. The oviferous sacs are of considerable size, cylindrical, and about two-thirds the length of the body. Length nearly 3 lines.

Male.—Somewhat pyriform in shape. Head very large, swollen. Thorax conical, divided into five segments, and terminated by a rudimentary abdomen armed with two small hooks. Antennae slender, setaceous, projecting from the anterior extremity of the head, and under-rath them a pair of bare and quite slender appendages, which are provided with mandibles; and behind the mouth two other pairs of foot-jaws are visible. Following these we observe two pairs of setiferous tubercles representing the feet. Length, a quarter of a line.

It is found attached to the branch of a sole.

2. L. cincta. Female.—Body somewhat square-shaped. Head small, and situated at the end of a long and slender neck; it is rounded at the anterior extremity, and a little below the antennae exhibits on each side a round lobe or tubercle. The antennae and foot-jaws are very small. The neck nearly equals in length the rest of the body. The thorax is broad, and of a somewhat quadrangular shape, with a deep indentation on each side about the middle of its length. On the upper half we see two pairs of prolongations or horn-like appendages, divided into three digitations; and on the lower half there are three smaller appendages, but simple, not digitated. The posterior angles of the thorax are prolonged also into short horns or appendages, which are also simple. The abdomen is in form of a short tubercle, with a rounded blunt point. The oviferous sacs are of about the length of the whole animal, of considerable size, and cylindrical.

The male is similar, according to Milne-Edwards, to that of Chondracanthus (Lernomena) cornuta.

It is found attached to the branch of the Triples.

3. L. Lophii. Female.—Body rather elongated, and somewhat gibbous. Head small, having on each side a small horn-shaped appendage directed a little obliquely backwards. Antennae small, conical, and slightly curved. Thorax divided into four portions by as many contractions. The first narrow like a neck, having on the upper portion a short spine, and on the under surface a pair of appendages or prolongations of two divisions or digitations; the second is somewhat quadrilateral, with on the middle line of the back two conical tubercles and on the sides two others, the upper pair the longest, and having on the under margin of appendages of two digitations; the third part is larger than the preceding, and has the same tubercles and prolongations, and in addition a small spine on the superior portion, and in the mesial line of the under surface; the fourth portion is rather the largest, with two horse or tubercles on the upper surface, a third on the median line of the under surface, and on each side a long terminal prolongation, rather blunt. Abdomen in form of a short tubercle in the centre of the posterior part of the body, arms very slender, and twisted. Length, 69 lines; breadth 21 lines.

The male is very similar to that of the Chondracanthus cornutus already described.

It is found on the Lophius piscatorius, in the pouches.

Tribe II.—Anchoracarpaceae.

Attached to their prey by means of two long appendages which arise from the thorax. They unite together either at the base or near the tip only, and terminate there in a rounded knob like a button, by means of which the animal maintains its hold of the part to which it has attached itself. No thoracic feet, or they are represented by these arm-shaped appendages.

Males in general differ very much in appearance from the females, being generally smaller and unattached.

Family 1.—Lernoepodada.

Arm-shaped appendages long, wide apart from each other at their base, and united only at the tip.

Genus Lernoepoda.

Female.—Body generally elongated, oval. Head short and thick. Two pairs of foot-jaws, well-developed, and placed near each other. External ovaries of moderate length and breadth.

Male.—Body divided into two nearly equal portions of an ovoid shape; one representing the head, the other the thorax. Much smaller than the female.

1. L. elongata. The head is very distinct, of a hurry texture, ovate, depressed, broad at the base, and obtuse pointed in front, resembling very much the shape of the body of the common Spider-Crab. The second pair of foot-jaws is large and well developed, consisting of a large rounded oval basal joint, and a more slender curved hooked terminal one, with a pretty strong tooth on its inner edge. The head is united to the body by a short narrow neck. A somewhat club-shaped form, and gives origin to two long cylindrical arms, which considerably exceed the length of the body. At the posterior portion, which is somewhat truncate, we see two small lobes; and on each side of them lie the ovaries, which are about the length of the entire body, thick, straight, and cylindrical.

Length of the whole animal nearly 8 inches. Head, one line and three-quarters. Body, 74 lines. Arms, one inch and one line. Ovaries, one inch and one line and a half. Male.

A specimen of this arctic species was found attached to the eye of a shark caught on the English coast, and brought to London in the winter of 1848.

2. L. Galei. Female.—The head is oval, depressed, and of a hard horny substance; the thorax is long, rather slender, and somewhat cylindrical, narrow where it is attached to the head, and nearly as large as that of a large的程度。The arms are slender, and nearly the length of the thorax. At the posterior extremity of the body are two small lobes, between which, on the middle line, is a small tubercle representing the abdomen. Ovarian tubes of moderate length, not quite equal in length of the body. Length of the whole body, including arms, about three-fourths of an inch.

Male.—Body divided into two portions, of an ovoid form, and about equal size; the upper half represents the head, and carries a pair of antennae, and two pairs of foot-jaws of considerable magnitude; the lower half, representing the thorax, has at its posterior extremity two sub-globular appendages a little longer than those in the female.

It was found attached to the cavity posterior to the vent of the Syngalus galeus.

3. L. Salmoena. Linnaeus's description of this species, as
far as it goes, is very good — Body ovate; thorax obcordate; the two arms linear, approximated. The head is rather small, somewhat bulging out at the back part, broader there, and rather sharp-pointed at the anterior extremity. From the base of the head spring the two arms, which are rounded, and slightly shorter than the body. The thorax is pyriform and short, and terminates at the posterior end of the two minute eminences. The oviparous tubes are of considerable thickness, cylindrical, and about the same length as the whole animal.

The colour of the animal is white. Length about half an inch.

It is found in the gills of the Salmon, in the London markets.

Family II.—Anchorellidae.

Arm-shaped appendages very short, and united to each other from the base, so as to resemble a single organ.

Genus Anchorella.

Female.—Body in general short, and somewhat swollen. Head small, and situated at the extremity of a long neck, which is generally curved backwards. Two pairs of foot-jaws well developed, and a third rudimentary. Antennae rudimentary. Oviparous tubes of moderate length, and cylindrical.

The male differs in appearance very much from the female, and is very small.

1. A. uncinata. Female.—The body of the animal is thick, oblong, of a milk-white colour, smooth, and opaque. Head very small, situated at the extremity of a long slender neck, which has a wrinkled appearance, and is nearly the length of the thorax. The arms spring from the upper part of the thorax, and are rather short, terminating in a rounded knob or button. At the posterior portion of the thorax there is on the middle line a small protuberance representing the abdomen. The oviparous tubes are cylindrical, straight, smooth, and about the length of the body. Length from 6 to 8 lines.

Male.—Body globular, terminated in front by a small conical eminence, at the extremity of which is the mouth, and having at its base one pair of rudimentary appendages, and a pair of rudimentary foot-jaws. On the middle of the body, on the inferior surface, there are two pairs of large hook-d-claw-like members. Length, one-fourth of a line.

The female fixes itself to the fins and gill-covers of the Cod and Haddock, and is most probably the most common species of our seas. (Johnston.)

2. A. rugosa. Body nearly of a square shape, a little emarginated on each side. Head small; neck slender, and nearly cylindrical. A rounded tubercle on the middle line represents the abdomen. Ovaries rather larger than the thorax, nearly cylindrical, or slightly club-shaped. Length, about 3 lines.

Found in the mouth of the Gadus celarius.

Tribe III.—Anchorellinae.

Females.—Attached to their prey by the anterior extremity of their body only, thrusting the entire head into the tissues of the animal to which they adhere, and being retained there by means of a kind of horns, which are various in form, and spring from the posterior part of the head. Antennae. Only one pair of foot-jaws, which is simple and hooked. Feet either very small or often wanting altogether.

Males.—Very small. Body globular, and more imperfect than in the preceding tribes, having no distinct thorax, and no rudiments of feet behind the appendages which represent the foot-jaws.

Family I.—Penioida.

Several pairs of feet situated on the under surface of the body near the head, but very small and rudimentary.

Genus Lernocera.

Body long, slender, narrowed anteriorly in the form of a neck, which is terminated by a swollen head furnished with two or three simple curved horn-shaped appendages. Abdominal portion of the body of considerable length, and simple. Oviferous tubes long and slender.

1. L. sprattus, the Eye-Sucker. Body slender, considerably larger at the posterior extremity than at the anterior. Head of tolerable size, rounded, and provided with two narrow rather hooked horns at its back part, directed backwards. The head is connected to the body by means of a long and very slender cylindrical neck, which is furnished with a dozen constrictions, which make the part of the body appear as if it were beset with an equal number of rings or knobs.

A short distance beneath the head it is very narrow, gradually increasing in size as it joins the body. Abdominal constrictions very distinct. Length about 14 in. W. long, and obliquely truncate. The oviparous tubes are very long and slender, about as long again as the whole body of the animal. Length of the body about an inch; ovaries one inch and a half.

It is found attached to the eyes of Sprats.

2. L. annulata. Body cylindrical, shorter than the preceding, and about the same size at both extremities. The neck is long and slender, quite smooth, and destitute of the constrictions which mark so decidedly the preceding species. The neck is white, and the body is of a brown, horrid colour.

The abdomen is like that of the preceding, and the oviparous tubes are long and slender, at least twice the length of the body. Turton describes the ovaries as "clear white." Perhaps they may be so in the living animal, but in the specimens preserved in spirits they are of exactly the same colour as the body. In one specimen however one of the tubes is broken, and the ova have escaped, and in this the tube is white. Length of the body about half an inch; ovaries fully one inch in length.

It is found attached to the bodies of the Chapea encaeuscola and C. sprattus.

Family II.—Lernoceridae.

No vestiges of feet on under surface of body, nor any appendages representing them.

Genus I.—Lernocera.

Body long and slender; head furnished with horn-shaped appendages, which are simple and symmetrical in form. Oviferous tubes straight, and of moderate length. Abdomen very small.

1. L. opercunae. Head furnished with four horn-shaped appendages, which are somewhat long and slender. The two outer or posterior are bifurcated; the anterior simple.

The thorax is very slender anteriorly, forming a long neck, but becomes much broader posteriorly, and when it terminates in the small abdomen appears obliquely truncate. The oviferous tubes are cylindrical, and rather long. The length of the whole animal is about 8 lines.

It is found on the sides of the Carp, Bream, and Roach, in many of our ponds and rivers, in great abundance.

Genus 2.—Lernus.

Body more or less twisted, and outre in appearance. Head furnished with horn-shaped appendages, which are irregularly branched. Oviferous tubes twisted into round masses, and placed under the posterior portion of the body. Abdomen of considerable size.

The genus Lernus is now restricted within very small limits. Established by Linnaeus upon the L. branchialis, it is at the present day confined to that species and one or two others.

1. L. branchialis. Head rounded, and furnished with three horn-shaped appendages, each of which is divided at the tip into three short branches.

The anterior portion of the thorax is long, cylindrical, and very slender, like a long narrow neck, while the body itself is very much swollen in the middle, and abruptly twisted upon itself in the form of a letter T. The abdomen is of considerable size. The oviparous tubes are slender and very much twisted.

The whole animal is about an inch in length, and is of a very firm consistence, being both hard and horny.

It is found on the gills of the Cod. (Baird, History of British Entomostroæ; Milne-Edwards, Histoire Naturelle des Crustacés.)

L. LETWICK. [Scole.]

LETTERKENNY, County of Donegal, Ireland, a market and post-town, and the seat of a Poor-Law Union, is situated on the side of a steep hill above the left bank of the Swilly, at about a mile above its entrance into Lough Swilly, in 54° 6' N. lat., 7° 45' W. long, 15 miles N. W. from Lisfard, 140 miles N. N.W. from Dublin. In 1851 the population was 1047, besides 233 inmates of the workhouse. The Poor-Law Union contains 14 electoral divisions, with an area of
101,507 acres and a population of 29,665 in 1861. The town of Letterkeny consists principally of one long straggling street, which however contains some good retail shops. The chief buildings are the parish church, a Roman Catholic chapel, an army depot, a post-office, a druggist's shop, a general store, a hotel, a masonic hall, a foreign mission station, and a school. The community is supplied with water from a spring about half a mile from the town, and admits vessels of 150 tons. The exports are chiefly corn, butter, cheese, and hides; the imports consist of colonial produce, manufactured goods, iron, coal, oak, bark, fish, etc. The scene of the Liven-Swilly above Letterkeny, and of Conaught and Sligo below, is as picturesque as any in the province.

LEUCHTENBERGITE. [Mineralogy, S. 1.]

LEUCIC ACID. [Chemistry, S. 2.]

LEUCINE. [Chemistry, S. 2.]

LEUCOJUM, a genus of Plants belonging to the natural order Amyllidaceae. It has a 6-parted perianth, bell-shaped; the segments are equal, and thickened at their points; the stamens are 3.

L. caeruleum, the Summer Snow-Flake, has a many-flowered spathe; a style thickened upwards. The height is from 2 to 3 feet. The flowers are white and drooping; the tips greenish. Leaves broadly linear, keeled; scape 2-edged; spathe usually as long as the flowers. It is found in wet woods, especially by streams.

LEUCOLINE. [Chemistry, S. 2.]

LEUCOPHANE. [Mineralogy, S. 1.]

LEYBURN, or LYE BURN. [Yorkshire.]

LIBERIA, Republic of, occupies a considerable extent of the west coast of Africa, and was formed into an independent state by an act of the United States—which declared itself an independent state, and carried in the affirmative.

The English government, which had displayed the friendliest feeling and rendered important assistance to the infant community, announced that it could not recognise the right of the Liberian authorities—the colony being neither an independent state nor an acknowledged dependency of the United States—to impose duties on goods imported into the country by British subjects. The Liberian council forwarded a resolution admitting that the time had come for the independence of Liberia to take into their own hands the whole work of self-government, including the management of all their foreign relations. According to this question was put to the assembled people whether they would declare itself an independent state, and carried in the affirmative. A convention was then appointed to draw up a constitution, and on the 24th of August, 1847, the flag of the Independent Republic of Liberia was hoisted in the ceremony. The chief events in the history of the settlement have been the numerous encounters with the natives, and since its independence the visits of the president to England and America with a view to the arranging of certain treaties. The republic was recognised by England as an independent state soon after its declaration of independence, and has since been recognised by France, Prussia, Brazil, and some other powers, but not by the United States.

Liberia has a general direction north-west and south-east, and is broken by several inlets and coves, of which those formed by Cape Mount, Cape Mesurado, and Bassa Cove are of much value as harbours. The greater part of the coast is low and sandy, or marshy; but Cape Mesurado has a range of water from 30 miles to the shore; and the shore is considerably elevated. Between those points however there is a low continuous beach of light brown sand, backed by an unbroken tract of forest. Towards the south-eastern extremity the coast is in many parts bold and rocky, and there are a number of cliffs in many places by which the sea is dashed against their bases. The sea is on the whole calm, with large irregular blocks of granite on the beach, over which the sea breaks heavily, and many rocks lie a short distance off the shore; but between the higher parts every thing is covered with thin layers of low sandy beach, in many places bordered by sand-banks: so that nearly all along the coast it is necessary for the mariner to keep a sharp look out. From the coast the land rises for the most part gradually towards the interior. About 20 or 30 miles from the shore is a succession of hills covered with grass, and far to the interior of the low country, with forests, rising farther inland into mountain ridges, and divided by wide and fertile valleys. The rivers are numerous, and some of them are good-sized streams; but all have their mouths obstructed, and some entirely closed, and the mountains obstructing the way to the sea do not appear to be navigable far inland. The chief river is the St. Paul, which falls into the sea by Cape Mesurado. The sand-banks at its mouth leave only a narrow channel for vessels to pass through. It is 60 or 80 miles in water the whole distance. Cape Mesurado is 30 mile wide 40 miles from its mouth, has a considerable body of water, flows through an extremely fertile valley, and has along its banks numerous native villages as well as settlements of the Liberians; but its course is greatly obstructed by rapids; boats of light draught only ascend it for about 35 miles. The other most important streams are the St. John, which falls into the sea at Bassa Cove; the Jambu, which lies between the St. Paul and St. John, and has a very considerable fall; the Narraga, which falls into the main river at its mouth; and the Monrovia, which rises to the north of the town of Monrovia, which falls into the sea by Cape Mount, and has its entrance almost closed by a narrow spit of sand; the Grand Cestos, some distance eastward; and the Doro, still farther east, which has about 6 feet of water over its bar, descending inside to 4 fathoms at flood.

The climate is hot and oppressive. During the dry season, which lasts from May to November, the temperature averages 85°; but in the wet season it falls to 75° or 74°. The extreme heat is alleviated by gentle breezes, which blow daily from the sea; and by the high temperatures of the interior, which visit all the newly-arrived alike, but is now comparatively seldom fatal in its attacks. Nothing like an epidemic has ever appeared in Liberia.

Lib. folio 358
Librarians to the Free Colored People of the United States" 1847, may serve, with allowance for a little heightening of the character and capabilities of the country:—

"A more fertile soil, and a more productive country, so far as it is cultivated, there is not, we believe, on the face of the earth. How much of all that has been written of its inferiority, which never fades; the productions of nature keep on in their growth through all seasons of the year. Even the natives of the country, almost without farming tools, without skill, and with very little labour, make more grain and vegetables than they can sell. Cattle, swine, fowl, ducks, goats, and sheep thrive without feeding, requiring no care but to keep them from straying. Cotton, coffee, indigo, and the sugar-canes are all the spontaneous growth of our forests, and may be cultivated at little cost, to arrive at a full share in real estate—citizenship belonging however exclusively to persons of colour; and of such, at present least, only to the free coloured emigrants from the United States, who immediately before their arrival in this country have held for a full term of years a grant of five acres of land, with liberty to purchase more. The executive government is vested in a senate elected from the counties, and a house of representatives elected after the American system, according to a ratio of representative population; and a president who is elected for two years, is to exercise supreme executive power, is the commander-in-chief of the army and navy, and has a qualified veto on the acts of the legislature. The judicature consists of a supreme court, a court of appeals; the justices are appointed by the president on a vote of two-thirds of the houses of legislature. The annual revenue and expenditure average about 7000l. a year each. The republic appears to be making steady progress.

There were in 1847 in Liberia (without including the Maryland colony) 93 churches with 1474 communicants, of whom 469 were natives; there are now above 300 churches. Schools are provided for all the children of citizens. In 1847 there were 16 schools with 688 scholars, of whom 192 were the children of native Africans: in 1861 the scholars were said to exceed 5000. Three high-schools are in operation in Monrovia; and an Act has passed the legislature for the establishment of a college. The 'Liberia Herald,' a very respectable newspaper, was established in 1845, and has been published for above 20 years; one or two others have been issued within the last few years.

LIBRARIES, PUBLIC. Up to a recent period one of the first things which struck a foreigner with pain when he first landed in Liberia was the absolute absence of libraries in the towns and cities, was the total absence of free libraries. In every large town on the continent there is a public library (often there are two, four, or six), to which every one is admitted at once, without introduction or guarantee. In the smaller towns, there is a public reading room in operation—Chetham's Library, in Manchester; and even this was so ill-managed in other respects as to be of hardly any use to the inhabitants of the town in which it existed. In 1849 a committee of the House of Commons was appointed, which Mr. Ewart was chairman, and its report contained a mass of startling facts, and a number of valuable suggestions. It was shown that our public libraries were not only difficult of access compared with foreign libraries—they were wretchedly few in number. One of the most striking things in this report is a map of Europe, shaded so as to exhibit the relative provision of books in libraries accessible to the general public in the various states on the continent, excepting Turkey. They show that a small German state, and France and England are on the two extreme verges. The minor countries are, in this respect at least, white with the light of science and learning, while the British islands appear to be in utter darkness. The gradations run down the scale thus:—For every 100 of the population, there are in the minor states of Germany 450 books; in Denmark, 412; in Switzerland, 350; in Bavaria, 340; in Norway and Sweden, 309; in Prussia, 300; in the Austrian empire and the kingdom of Hungary, 299; in France, 188; in Austria, 180; in Spain, 176; in Portugal, 100; in Russia, 75; in Holland, 63 to 53; in Great Britain and Ireland, 63 to 53. Look at it how we will, such a table is calculated to put one to the blush; but after all it should be remembered that we cannot undertake out some sort of explanation. Such a statement is very likely to mislead colonial writers, not well acquainted
with England, into a grievous mistake. It is only too true that the peasant of Durham has fewer books accessible to him in public-collections than the peasant of Podolia or the Banat has—the citizen of London or Liverpool than the weaver of Catalonía and the vine-dresser of Caratia. B. It is not true that there are more books in Russia and Hungary, in Spain and Sicily, let us say, in the small principality of the Corsicans, than in Holland and England. It is not even true that there are more books accessible to the working classes in any of the countries named than in England. There are coffee-houses in the bye streets of London which have better libraries than can be found in cities of from five to ten or fifteen thousand inhabitants in Germany or Denmark. There are divans in the Strand where more papers and reviews are taken in than in the Casino of Frath. In fact, with the exceptions of Italy, Greece, and the Spanish States, no country in the world has so many books, so much literature, in proportion to the amount of the population, as England. In Spain, in Italy, and Germany, even in France, very few persons have private libraries in their own houses. In England a house is not considered furnished without a stock of books. Even the cottage of the peasant has its family Bible, and its copy of Shakspere or Milton, a thing having no parallel in any of the countries standing higher in the above list. It is a sort of gift presented by foreigners, and in England there are no pictures. It is much the same with regard to books. But the fact is, both our art and our literature are gathered up in our houses; while in public collections we are lamentably deficient, but only in public collections.

This want, as of books, of pictures, and in small quantities, and in many houses, has its evils as well as its virtues. It induces a certain amount of reading in the classes to whom literature is chiefly a graceful recreation; but the education of the masses to the higher culture of men of letters, as if by it most deplorably. Within the recollection of men still living there was no library in London, accessible to the public, even moderately complete in the great departments of inquiry. Gibbon had to purchase all the books necessary for the composition of his most great work. Fortunately for us he had the means. Roscoe was unable to obtain from any public library in Liverpool the ordinary Italian authors whom he had to consult on the subject of his two biographies. Still later than this, the historian of North America (Graham) found himself obliged to remove from London to Gottingen, in the same time to get access to a well-stored library, which was at the same time open to the public. Within a year or two of our own time, Robert Sou-hey was obliged to collect at his own cost all the materials of his voluminous writings, as any other author would have to do again next year, if it were inconvenient for him to reside in London, and to attend at the British Museum in the heart of the day. How disastrous to such works, publicly accessible, operates upon the current literature of the time. No one, in fact, is able to know the present literary literature, is alone truly aware. How it operates to prevent the spread of sound and useful information among the masses, is evident to every one who has been in the habit of reading in the libraries of the capital. The case is even more in comparison, the reading rooms, day after day, of the British Museum and the National Library in Paris, he will at once perceive that two distinct classes of persons frequent these rooms. In London he will find men, women, letters and artists, the teachers of the people. In Paris he will find other that it is the people themselves who come to read. In the British Museum he sees only grave men and women dressed in the customary suits of solemn black, so well befiting the avocation of letters. In the British Library the visitors are less respectful, the men from civil and military colleges, soldiers of the line in their blue-coats, officers, clerks, shopkeepers, porters, and generally speaking speaking scribes of all classes of the population. A peep over the shoulders of the readers in the two rooms will reveal another difference between them. In London, you see the tables covered with old volumes, maps, and manuscripts—the literature of the past. In Paris, you notice that the readers are chiefly poring over the new books and new writers—The literature of their own age. In strict truth, the British Museum is only a library of reference; the Parisian institution is a library for reading.

This is not in the theory of the two institutions which ought to lead to this variety of result; but practically it is so; and the circumstances in which the rules are founded are sufficient to explain it. The National Library is open to the public—the British Museum is not. Whenever a man finds himself in the heart of Paris with an hour's leisure on his hands, he can at once repair to the Library. No one can do this in London unless he is previously provided with a free card. The Parisian who obtains an unexpected holiday can use the institutions of his country—not so the Londoner; for although it is not difficult to get a pass card to the British Museum, it must be obtained the day before, and not in London, as Parisians can. This is the greatest advantage which the masses of Paris have over the same classes in London. To the man of letters, Paris offers still greater advantages—particularly, under proper regulations here allowed to take home with him the books he is using for literary purposes. How far in the opinion of the Committee these provisions might be safely extended to the British Museum readers, will be considered by and by.

It appears from the evidence tendered to the Committee, that,

In France there are 107 Public Libraries open freely.

- Belgium . 14
- the bishop of Bruges . 44
- Austria (with Venice and Lombardy) 48
- Saxony . 6
- Bavaria . 17
- Tuscany . 9
- Great Britain and Ireland . 1

All the great public libraries on the Continent are like the National Library in Paris; that is, they are open freely to all comers without distinction of person, rank, or country. This is as it should be everywhere; none should be sent back from the temple of knowledge who knock for admission. The following list gives the number of these public libraries in the chief capitals in Europe:

In Paris there are 7 open Public Libraries.

- Brussels . 2
- Berlin . 3
- Milan . 2
- Dreden . 4
- Munich . 2
- Copenhagen . 6
- London . none

Compared with the population of these cities thus provided—the whole of them little over-counting London alone—the facilities for mental culture afforded to our masses are not to be named. Indeed all the collections of books which can by any straining of the terms of their acts of foundation be considered as public libraries are wretchedly inadequate to meet the wants of a population pining for a higher class of reading. There is no hope for the future—there is no hope of any improvement—of the library of Sion College, in London Wall, founded by Dr. White, in 1636, and now containing nearly 40,000 volumes; the library in Red Cross Street, founded by Dr. White, which is now containing about 30,000 volumes; and Archbishop Tenison's library in Westminster, containing about 4000 volumes. This last is now degraded to the purposes of a club-room. These are all public; a card of admission is obtained in much the same way as at the British Museum. Of course there are many other libraries in London to which men of letters obtain access for the objects of their craft—such as the library of the East India House in Leadenhall Street; the libraries of the Inns of Courts; libraries connected with the various learned institutions; the library of Lambeth Palace; and so on. But from none of these can the books be borrowed. None of them are open to the general public, or to the unknown student. The only decent library in London from which books may be taken home is a subscription library in St. James's Square—and even that is necessarily very imperfect in all departments, and is moreover barricaded by a large entrance fee.

Out of London, the Bodleian at Oxford, and the University library at Cambridge, are the best in England. Get the latest books more easily to the public; and not on one, but to the majority of the students themselves. It is the same in the University library in Glasgow. At Trinity College, Dublin, at the University Library of Aberdon, and at that of St. Andrews, the books are reading and at the disposal of the public. Chetham's library, in Manchester, containing about 20,000 volumes, has the reputation of being the only one in England open to the public after the manner of the Conti-
In Dublin, there are four other decent libraries in addition of that of Trinity College—belonging respectively to the Royal Irish Academy, 10,000 volumes; to the Royal Dublin Society, 19,000 volumes; to the Queen's Inn, and Marsh's Library, 18,000 volumes. The University Library in Edinburgh is the chief public collection of books in the east of Scotland.

Besides these great collections, which are known but not easily accessible to the general public, there are a consider- able number of town and parochial libraries, which are scattered about the country, which at present are neither known nor accessible—but which may constitute the nuclei of a system of public libraries by and by. These little-known and little-used institutions are, as it were, the parochial libraries. Of the cathedral collections there are known 34 in England and 6 in Ireland. For the most part they are stocked with works on theology and divinity, but some of them have also works on literature and history—particularly ecclesiastical history. Many of these have incomes settled upon them by pious and munificent founders. In such as have, new books are added yearly; the number of volumes which they contain will average from 7000 to 10,000 in each one. In such as have not, they have had little care taken of them, and much loss has therewith been to the public. Generally speaking, these church libraries are the closest of corporations. Parochial libraries once prevailed to a considerable extent throughout England and Wales, and Scotland. Persons have been known to contribute as much as 136 such institutions in England and Wales, and 16 in Scotland. These parish libraries were founded in the first instance by private benevolence. Many of them owed their origin to the efforts of Dr. Bray and his friends, the founders of the clergy, at a time when standing armies were at the beginning of the 18th century; but others had already been in existence some time, as we learn from the preamble to an Act of Parliament for their better preservation, passed in 1770, that some of these libraries had fallen into a state of decay. It is stated in evidence that "the books lie exposed to chance, and liable to be torn by the children of the village;" as however they were originally formed chiefly with a view to their being useful to the poorer ranks of the clergy, at a time when the standard works were dear, and few parsons could boast of a well-stocked set of shelves, the works which they contain are by no means fit only for children. They are generally of a high class; but there are not very many of them unfortunately.

That the public required greater facilities for consulting better works than they possessed, was proved—first, by the more educated classes continually making our national poverty in this respect the subject of complaint in the press and in literary conversations. History, poetry, travel, political works, and so forth, books of solid thinking and high character also find their place. A cursory glance at these places, lycemns and coffee-houses, will show that the man of business, the merchant, the tradesman, the man of leisure, and the student, all use them. Such considerations as these convinced the Committee of Inquiry, that the establishment of public libraries, open and free to all comers, was a national want, expressed in the most practical and convincing manner.

The Committee were chiefly for the purpose of rendering the existing libraries more available to the general public, with occasional grants from government for the purpose of extending them. They were not adopted altogether, but the Report produced such a conviction of the necessity for doing something, that in 1850 an Act was passed (13 & 14 Vict., cap. 65) "for enabling town councils to establish public libraries and museums." There had been a previous Act in 1845 for enabling them to form museums in towns or boroughs where the population exceeded 10,000. The town councils were by the Act directed to secure, with the consent of a majority of two-thirds of the persons legally entitled to vote in an assembly called for the special purpose, to levy a rate not exceeding a halfpenny in the pound on rates for the poor rates, and for the poor rates, and to hire or purchase land, erect buildings, furnish them suitably, appoint and pay officers, &c.; the property in buildings, books, maps, specimens of art and manufactures, or purchased or acquired by donations, to be vested in the corporation on trust to be let, lent, or sold, provided that such towns or boroughs are without a city, town, or borough and other resorting thereto; the admission to such libraries and museums to be at all times free of charge. This Act was extended to Scotland and Ireland by the 17 & 18 Vict., cap. 74. Numerous towns have availed themselves of the powers of this Act in England; among others, Birkenhead, Bolton, Cambridge, Hertford, Kidderminster, Liverpool, Manchester, Norwich, Oxford, Salford, Sheffield, Warrington, and Winchester. The general results are reported in every instance to be very satisfactory. At Salford, in the first year, out of 3000 consecutive issues of books, 1331 were works of fiction; in 1855, out of the same number, only 720 were works of fiction. At Oxford it is said 535,000 volumes have been issued within the past five years; while during those five years, books, we presume, are meant, and not distinct persons; and it is reported that the public library "has proved of more real benefit, and rendered more solid advantages to the middle and working classes in this city than any other measure which has been adopted." In Cockermouth, it is said that, "a marked improvement has been noticed in the habits and manners of the people who frequent the library." The return also mentions that in Birmingham, Cheltenham, Exeter, Islington, and the City of London, the proposal for establishing a public library has been rejected.

One of the suggestions of Mr. Ewart's Committee was that, wherever the public were admitted to libraries, gas should be provided, that the artisan might use them in the evening. In most of the libraries estab"lished under the Act, the suggestion has been adopted. Another suggestion, that the library of the British Museum should be to a certain extent divided, one division containing those works best adapted for general reading, to which the public might be admitted in the evening, and the other, the great national collection of records, manuscripts, and books of reference, for literary men, has not been attempted. Such a division would certainly be a great benefit to both classes of readers. In the British Museum in London, the large and elegant new reading-room of the British Museum, even under the restriction of obtaining pass-cards, has yet too many readers to be pleasant for a student. If also, as in Paris, books could be had for a limited time to be used at home by the writer who, in fact, may readily refer, without the expense of travelling, at large, it would be an invaluable boon.

LINDE, SAMUEL BOGUMIL, the great lexicographer of Poland, was of immediate Swedish descent. His father was a native of Dalscarnia, which was settled at Thorn in Poland when Linde was born in 1774. After a good education in the schools of Thorn, he was sent, at the age of eighteen, to study in the university of Leipzig, where he attracted the favourable notice of Professor August Wilhelm Eulenberg, a well-known author and teacher. After some years of study, Linde, in one of the prefects to his great work, the Polish Dictionary, "struck out for me, without my knowledge, an opening to a career which he thought would be for my benefit. One day he told me, to my great surprise, that he had written a book. I was therefore surprised to hear that a chair of the Polish language and literature should be entrusted to me at the university of Leipzig. I told him, with some consternation, that I was not well acquainted with Polish; that all I knew of it was what clung to my memory.
from the mere intercourse of daily life at Thorn, where I was much neglected; and that if I were made professor I should myself be obliged to begin to learn the language anew from the first rudiments."

In the course of 1782, however, Linde received the appointment, and began to do as much as he could among the Polish that he procured from Poland was the 'Polish Psalter' ('The Return of the Polish Psalter'), a satirical play, directed against the national failings of the Pole, which he found so excellent, that, though many passages were beyond his comprehension, he commenced a translation of it with the intention of making use of the original as a sort of study with his pupils. It was lying on his table when two Polish gentlemen called on him, whose attention was at once attracted by the book, and he asked them if they could inform him who was the author of that anonymous work. One of them, Niemiec, replied, "I wrote it." "That moment," Linde afterwards said, was "the decisive moment of my life." Niemiec was his intimate friend, explained to him the passages that had perplexed him, and introduced him to the society of the other distinguished Poles then living at Leipzig, to which it appears the professor had hitherto had no access. Among them were the Counts Potocki, Koliotaj, and Thaddeus Kocieciusko, some of the most illustrious names of Poland. Linde, who had been first heard of in Poland by the lips of gentlemen and scholars, became fired with enthusiasm for the Polish language, and resolved to devote himself to the production of a great Polish dictionary. He took this resolution on February 2, 1784; he published the last volume of his great work two years and a half after, having worked at it almost unceasingly during the interval. The Dictionary of the Polish Language, 'Słownik Języka Pol斯基go,' occupies six quarto volumes, of which the first was published at the beginning of 1784, and the last in 1786. It is divided into about five thousand quarto pages in closely printed double columns; to every word is appended an explanation in Polish and German, a comparison with the forms which resemble it in the other Slavonic dialects, and a collection of passages from authors in which the word is used. Linde read through six or seven hundred of the principal works in Polish, of which he gives a list in the first volume. It was the first great dictionary of the Polish language; it has been in use for more than a century, and is the only one of which the text, though of course susceptible of improvement and augmentations, is not likely to be ever either superseded or surpassed. In the course of its preparation Linde soon resigned the professorship at Leipzig, which had first given rise to it, passed some time at Warsaw, then became librarian to Count Omelinski at Vienna, and had the congenial employment of travelling in Poland to collect Polish books, by which he enriched the library and his Dictionary together, and lastly established himself in Warsaw, in which city, which he carried on in his own house by composers and pressmen, some of whom had the privilege of immortalising themselves by affixing their own names at the end. These labours were carried on during a stormy period, but the house in which the Dictionary was published was never subsequently one, and the. extension of the work was repeated by succeeding armies, and the author received support from the Prussian and the Austrian governments, and in particular from the Russian, as well as from numerous Polish magnates, one of whom, Count Zamorski, when the works on one occasion brought to a standstill by an absolute want of pecuniary means, sold a favourite horse and sent the proceeds to the lexicographer. Linde held various appointments connected with the educational establishments of Poland, and was enabled to introduce extensive improvements. He was one of the most esteemed and respected men of his time, and was always an honest friend to his native country, and as such he was always in demand. He died in Warsaw in 1801, at the age of 72, after a long and prosperous life. The Dictionary was completed and published under the title of 'Catholic Loyalty vindicated,' 1810. He afterwards wrote several controversial pamphlets, which in 1813 were published in a volume under the title of 'Treaties on several Subjects connected with the Civil and Religious Principles of the Catholics;' and he was also the author of 'Catechetical Instructions on the Doctrines and Worship of the Catholic Church,' of which there were several editions. In 1836 he published an English translation of the New Testament, which is said to be accurate and faithful in several passages where the Donat translation is faulty. In 1845 he published the 'History and Antiquities of the Anglo-Saxon Church,' 2 vols. 8vo.

Dr. Lingard's great work, the 'History of England from the First Invasion by the Romans to the Accession of William and Mary in 1688,' was first published in 6 vols. 8vo, London, 1810,25-26; second edition in 14 vols. 8vo, 1833-34; fifth edition in 9 vols. 8vo, 1849-50; and sixth edition, 10 vols. 8vo, 1854-55. Dr. Lingard's 'History of England' is a work of great research, founded on ancient writers and original documents, displaying much erudition and sententious, and opening fields of inquiry previously unexplored. The work is well written, and the dates accurately given, and the authorities referred to distinctly. The style is perspicuous, terse, and unostentatious. The work perhaps exhibits too exclusively the great facts and circumstances, military, civil, and ecclesiastical, and enters less than might be desirable into the manners, customs, arts, and condition of the people. In all matters connected with the Church the work is, as might have been expected, coloured by the very decided religious opinions of the author. His views on the subject are not of a compromising nature. Dr. Lingard, after the completion of his 'History of England,' paid a visit to Rome, where Pope Leo XIII. offered to make him a cardinal, but he refused the dignity. He spent the last forty years of his life at Hornby, near Lastingham, where he died July 13, 1851. He was buried in the cemetery of St. Cuthbert's College, at Ushaw, to which institution he bequeathed his library. His later years were rendered comfortable by the profits of his 'History,' and a pension of £150 a year from the Queen for his services to literature.

LINOSYRIS, a genus of Plants belonging to the natural order Compositae. The heads are not radiant; florets all perfect and tubular; receptacle naked, pitted, the pappus of soft, silky, entire, white hairs imbricated; pappus piliolous; fruit compressed, silky, without a beak.

L. vulgaris is an herbaceous Plant, found in middle and
southern Europe and Great Britain. It has linear glabrous leaves, corymbose heads, the involucre lax; the stem from 12 to 18 inches high, simple and leafy; leaves single ribbed, smooth or scabrous, very numerous, more or less dotted: flowers yellow. It grows on limestone cliffs. It is the characteristic limestone of South London.

LINESERZ [Mineralogy, S. I.]

LINTON. [Cambridgeshire.]

LISTA Y ARAQUON, ALBERTO, an eminent Spanish mathematician, was born in Madrid, in 1778; and in 1797, when he was but fifteen years old, he composed a treatise on the theory of numbers, which was highly praised by the mathematicians of his time. His mathematical knowledge was profound, and his mind was quick and analytical. He was a brilliant student, and his work was characterized by originality and accuracy. His mathematical writings were widely read and admired, and his influence on the development of mathematics in Spain was considerable.

Athenaean, or university there. His health suffered by the climate of Madrid, and he removed to Cadiz, where he superintended the new college of St. Philip Neri. In 1840 he gave up this duty, and returned to his native Seville, on his way to which he was met at two leagues off by a procession of friends and admirers, who escorted him to his home. He was one of the foremost mathematicians of his time in the city where his early triumphs had been won, and there he died on the 6th of October 1846. The municipality of Seville erected a monument in his honor, and his name was added to the list of the benefactors of the town.

Lista was an author of very various merit, his 'Tratado de Matematicas para y mixtas' is the standard book on mathe-
matics in Spain, and his 'Ensayo de la geometria y criticas' is considered little inferior to that of the admired Melendez. His philosophical poems in the style of Horace are peculiarly happy, and his sacred poems are superior to those of any of his contemporaries. A literary critic has published 'Lecciones de Literatura Dramatica Española' (Madrid, 1829), and his 'Ensayos Literarios y Criticos' of 3 volumes, Seville, 1844, are in high esteem, and contain a fund of valuable information for foreigners; and he has also displayed his intimate acquaint-
ance with his countrymen by publishing an excellent col-
lection of selected extracts, 'Trastos Encogidos de los mejores Habilidades Españoles en Prosa y Verso'. A translation of Seguer's French work on universal history, which he executed while in France, has a title to be mentioned from the numer-
ous additions and comments, among others, a history of Spain to a late period. As a political writer he was dis-
tinguished by his advocacy of moderate and cautious reforms; and it should be mentioned that among his poems is one entitled 'The Triumph of Tolerance', directed against the Inquisition.

LISSEMMUS. [Elatrichide.]

LISTERA, a genus of Plants belonging to the natural order Orchidaceae. It has a ringent perianth; a deflexed 4-lobed lip; the stigma truncated; the ovary 4-celled, entire, acute, with a minute globose appendage at its some-
what reflexed apex; column very short.

L. ovata, Twy-Blade, is found in woods and pastures in Great Britain. It has 2 opposite ovate leaves, the lip bifid, column with a crest which includes the anther; the stem a foot high; spike elongated, very lax; flowers small, and greenish; leaves large.

L. cordata has 2 opposite cordate leaves, 4-lobed lip; the stigma truncate; the ovary 4-celled, entire, acute; at the margin of the leaves.

LITHOSPERMUM. [Mineralogy, S. J.]

LITIORELLA, a genus of Plants belonging to the natural order Plantaginacea. It is monocious; the male flowers stalked; sepals 4; tube of the corolla cylindrical; limb rounded; stamens hypogynous; filaments very long. The female flowers sessile; sepals 3; corolla oblong, narrowed at both ends; styles long; capsules 1-seeded.

L. laxianum, has white flowers; the fertile flowers sessile; stalks of the male flower one to two inches long; leaves all radical, linear, flexuus, somewhat channelled. It is found on rocky mountains in Great Britain.

LITHOMARGE. [Mineralogy, S. J.]

LITOSPERMUM. [Montgomeryshire.]

LITFXYLLIN. [Montgomeryshire.]

L. A. ROWE. [Montgomeryshire.]

LOCHE, JAMES, a native of Scotland, was born at Drylaw, near Edinburgh, by a sister of the late Right Honourable William Adam. He was born in 1780, and called to the Scottish Bar in 1801; he was subsequently admitted within the English Bar, and in 1825 was admitted to the late Earl of Carlisle, and to the trust estate of the late Earl of Dudley, Viscount Keith, and also to the extensive properties of Lord Francis Egerton (afterwards Earl of Ellesmere), and his brother the Duke of Sutherland, which he received from the late Earl of Carlisle, and which, during the period when the title of Highland emigration had set in at its strongest. The improvements which were made on the Duke of Sutherland's Highland property were the subject of much controversy, and the late Lord Chief Justice of Scotland, Lord Cockburn, in some able publications, demonstrated that the remark of that prince was not applicable to any means of cultivating the land, to make room for profit-
able industry, was real benevolence. He was also well known as the author of a 'Statistical and Historical Account of the...
County of Sutherland,' and as a member of the council of the University of London. He represented in the Liberal interest the North West division of the Borough of South Cornwall, during the last unformed parliament, after which he sat for the Wick district of Burghs from December 1832 to the dissolution in 1832, when he finally retired from parliament. He died in Albermarle-street, London, July 8th, 1845.

LOCKMABEN. [DUMFRIESSHIRE.]

LOCHWINNOCH. [RANSTRAYSHIRE.]

LOCKER, EDWARD HAWKE, was the son of Admiral Locker, to whom Nelson, soon after the battle of the Nile, thrice presented as a young man, and whom he encountered in the early days of his acquaintance, know that nothing can alter my attachment and gratitude to you. I have been your scholar. It is you who taught me to board a French man-of-war by your conduct which in my mind was as you would wish it. I have no Frenchman close and you will best him; and my only merit in my profession is being a good scholar." The son, Edward Hawke Locker, was born at East Malling, Kent, on the 9th of October 1777. He was educated at Eton, which he left in 1786, and received an appointment in the Navy Pay Office. He remained in government offices till 1800, when he went to India as private secretary to Lord Exmouth. From that time till the peace of 1814, he was associated with that distinguished commander in arduous and confidential duties, especially when, as Pay Master General, he was sent to the Mediterranean, which he discharged with eminent ability. In his official capacity he visited Napoleon at Elba in May 1814; of which visit he published an interesting narrative after the death of the Emperor. Mr. Locker was afterwards the President of an eminent antiquary and philologist, the Rev. Jonathan Boucher, the author of a ' Provincial Glossary,' the publication of which from the posthumous manuscript commenced in 1802, but which has not been continued beyond the first. R. B. Locker resided at Windsor from 1815 to 1819, when he was appointed secretary to Greenwich Hospital. During his residence at Windsor his attention was called to an article in 'The Windsor Express,' in which was pointed out the want of books suited to the large class who had learnt to read under the new system of education in National and other schools. Mr. Locker sought the acquaintance of the writer of that article, Mr. Charles Knight, then the editor of the Windsor paper; and they together projected and joinedly edited 'The Plain Englishman,' almost the first, if not the very first of any literary pretension, of those cheap and popular miscellanies which the growing ability of the great bulk of the people to read impressively demanded, in the place of miscellaneous or childish trash. Mr. Knight, a friend and admirer, as the present Archbishop of Canterbury, were among its contributors. Mr. Locker's own papers in the miscellanies are excellent models of popular writing—plain, energetic, affectionate, and unaffected, which, on the British soil, have been reprinted in a separate volume; 'Lectures delivered to the Crew of the Caledonia, Lord Exmouth's flagship,' are admirable examples of clear exposition and earnest exhortation. Mr. Locker, after filling for several years the important duties of secretary to Greenwich Hospital, became the Resident Civil Commissioner of that great institution. The improvements which he introduced into its management were results of his active and comprehensive mind. Of these improvements the Naval Schools are striking instances. Himself an accomplished draughtsman and an ardent lover of the arts, he founded the Naval Gallery at Greenwich by his judicious exertions. In 1844 Mr. Locker's health so failed that he gave up his valuable appointment and retired upon a small pension, his fine faculties exceeded beyond the hope of recovery. Mr. Locker was the intimate friend of many distinguished men amongst his contemporaries. To use Mr. Lockhart's expression, he was an 'old and dear friend of Scott.' He died on the 15th of October 1849.

LOCKERBIE. [DUMFRIESSHIRE.]

LOCKHART, JOHN GIBSON, was born in 1794 at the manse of Cambusbethan, in Lanarkshire, Scotland; his father, who was an old Lanarkshire family, being then minister of the Established, or Presbyterian, Church of Scotland. His mother was related to the celebrated family of the Erskines. When Lockhart was two years of age, his father removed from Cambusbethan to Glasgow, which was about one mile west of the city, where he resided in a small house near the Custom House. John Lockhart was educated. His talents were shown during his course at the Glasgow University; at the end of which, while still only in his sixteenth year, he obtained, by the unanimous voices of the professors, the Smellie Scholarship. In 1811 he was granted B.C.L. at the University of Glasgow. He could not, however, either on the same exhibition or otherwise, obtain a sufficient income to enable him to support himself either in Scotland or in Germany, and acquiring the language and seeing much of the literary society there, he settled in Edinburgh as a member of the Scottish bar in 1816. He never had much practice as a lawyer however, but from the time he was first met to the end of his life, he was associated with the little band of young Scotch Tories, who, with Wilson as their chief, were then beginning to dispute the literary supremacy of the Scotch Whigs, as represented by Jeffrey and his 'Edinburgh Review.' When the 'Black-Hart' was in existence, he was one of its chief contributors; and considerable portions of the famous 'Chaldee Manuscript,' and of the earlier 'Nec toes Ambrasienses' papers were written by Lockhart, though Wilson afterwards made the magazine his own. He was in consequence of Lockhart's lifelong connection with 'Blackwood' and Scottish Toryism that he became acquainted with Scott, who looked with a kindly interest on the efforts of these young men of the same politics as himself. The first meeting of Scott and Lockhart took place in 1816, when Lockhart, in a letter to his friend John Wilson, then editor of the 'Edinburgh Annual Register,' recommended Lockhart to the Ballantynes as his substitute. In 1819 Lockhart was appointed editor of another Edinburgh periodical, the 'National Magazine,' which gives such graphic accounts of Scottish men and manners at that time. In 1820 he married Scott's eldest daughter Sophia, and took up his abode at the cottage of Chieflawood, close to Abbotsford. How perhaps he spent his happiest days and few passages in Scott's life are pleasant rather than those describing his walking over early in the morning to breakfast with the young couple at Chieflawood, or helping their servants on a summer afternoon, when they were both out of doors. As a writer he contributed to 'The Blackwood' and to the 'National Magazine' for six years; and from 1829 to 1832 he edited the 'Companion.' At this time he published the 'Life of Napoleon,' for 'Constable's Miscellany.' In 1836 Lockhart removed to London to succeed Gifford in the editorship of the 'Quarterly Review.' He continued to edit it until his death, and the name of Lockhart is associated with every page of it so well known. In his hands the 'Review' maintained and increased its reputation; and not a few of the most powerful articles that appeared in it during the seven-and-twenty years of his editorship, came from his own pen. He was particularly happy in biographical sketches, combining with the utmost criticism. One paper of this kind—that on 'Theodore Hook,'—has been reprinted by itself. On Scott's death in 1832, the task of writing his biography naturally devolved on his son-in-law Lockhart. The task was accomplished in 1837-39, when the voluminous 'Life of Scott' was given complete to the world. Those portions of the work which related to the fall of Scott's pecuniary fortunes, provoked some controversy at the time; but the work as a whole has now taken its place as one of the most interesting and admirable biographies in the language. It has been said by those who knew Lockhart, that such was his practical sagacity, that his illustrious father-in-law had the benefit of his actual assistance in the management of his affairs. Of this it is difficult to say whichruined the close of his life could certainly never have happened. In 1843 Lockhart was appointed by Sir Robert Peel to the office of auditor of the Duchy of Cornwall, with a salary of £3,000 a year. He was a man of very moderate income who he had inherited some family property, he was in very easy circumstances. His last years however were embittered by a series of bereavements. His eldest son, the 'Hugh Littlejohn' of the 'Tales of a Grandfather,' had died in early life; his wife died in 1837; his second only surviving son died at a later period; and there remained only...
one daughter. This lady, who was also (by the death of Mrs. Locker, his eldest brother childless in India, that of the younger brother unmarried, and that of her sister) the sole remaining descendent of the family, married Robert Hope, Esq., barrister-at-law, and is now proprietress of Abbotsford. Along with her husband she embraced the Roman Catholic faith. She usually lives at Abbotsford, and has a daughter, born in 1822. Locker, broken in health and spirit, lived to see his own pedigree and that of Scott centred in this child—his grand-daughter and Scott's great-grand-daughter. Gradually becoming more shattered, he resigned the editorship of the "Review," and went to Rome. To support property in Scotland he retired to Scotland. He died at Abbotsford, November 25, 1854, in the sixty-first year of his age. To the last he retained something of the handsome aristocratic appearance and the manners, always reserved, had become chillingly so before his death; but those who knew him intimately, maintain that, beneath his morose and iron demeanour, his scornful smile, and his withering sarcasm, there lay a host of qualities which commanded the thorough respect and affection of those whom he did admit to his friendship, or who were related to him by blood or affinity.

LOGANIACEAE. Logania, a natural order of Exogenous Plants, consisting of shrubs, herbaceous plants, or trees. It is characterized by a perfect staminate flower, usually without stipules, which adhere to the leaf-stalks or are combined in the form of interpetiolar sheaths. The flowers are racemose, corollary, or solitary; the calyx valvate or imbricate, the corolla villose, the anther 4-5-6-10-cleft, with valvate or convolute masturbation; stamens arising from the corolla, all placed upon the same line, and not always symmetrical with the divisions of the corolla, pollen with 3 bands; ovary superior, 3-celled; ovules solitary or in small axillary clusters; fruit either capsule, 3-seeded, with placenta finally becoming loose or drupaceous, with 1-2-3-seeded stones, or buried with the seeds immersed in pulp; seeds sometimes winged, usually peltate, albumen fleshy or glabrous; embryo small, with the radicle turned towards the umbilicus. All parts of the plant are aromatic. They are either tropical or inhabit countries near the tropics, a few in America and Australia forming the only exceptions. It would be difficult to name a more poisonous order than this, of which the celebrated Usus vomiun may be taken as representative. Notwithstanding the active qualities of these formidable plants, some are used in medicine with great advantage. Several of the species of Strapacos are used in the East as remedies for various disorders. Onaman, a variety of Cineraria, and the Beas, are employed in India for cholera. Speciosa yields also several species which are employed for useful purposes. The order consists of 22 genera and 162 species. It is related to the Commelinaceae and to the Commelinaceae, and is used by the Balsas. The usages of the species will be found under their respective heads, Spokkia; Strachan; &c.

LONDON PRIDE. [Saxitraga.]

LONDONDERRY, CHARLES WILLIAM VANE, THIRD MARQUIS OF. E.P., O.G., G.B.H., only son of Robert, first Marquis, by his second wife, Frances, daughter of Lord Chancellor Camden, and half-brother of Robert, second Marquis [5.1], was born in Dublin, May 18, 1778. Charles William Stewart was in his fifteenth year when he received his first commission as ensign in a foot regiment, and embarked under the Earl of Moira (afterwards Marquis of Hastings), to relieve the Duke of York from the perilous position in which he found himself after the reduction of York and the capture of Charlestown. Having held this post for a few months the post of Assistant quartermaster-general to a division of the forces under General Doyle, he was attached in the following year to Colonel Crawford's mission to the court of Vienna; and while thus occupied he received a severe wound at the battle of Deslanes. Returning home, he was appointed to the command of the 15th Light Dragoons, by which he accompanied to Egypt under Sir Ralph Aber-
ing an elongated body, with dorsal fins and one anal fin, a chum with one or more barbules. *L. melops.* The Ling, is a very valuable fish, scarcely less so than the Cod, and already taken among the Western Islands, the Orkneys, on the Yorkshire coast, and the Scilly Islands; and may be traced nearly all round the Irish coast. The fishing for them is by hand-lines and long-lines; and besides a portion that is consumed fresh, the remainder is mostly used to salt, cleaned, bled, washed, and dried, but the demand generally falls short of the quantity cured, and the hardy fishermen are but poorly requited. The ports of Spain are the markets supplied; and so extensive an article of commerce in Ling fish is considered as formerly an Act for regulating the price of Ling, Cod, &c., was passed as early as the reign of Edward III. The air-bladders, popularly called Sounds, are prepared separately, and with those of the Cod-Fish are sold pickled. The roes, which are very large, are also salted, as food, or preserved in brine are sold to be used for attracting fish. The liver produces oil, which is used by the poor to supply the cottage lamp, also as a medicine. In Zeland the principal fishing for Ling is from May to August. On the Yorkshire coast the young are called Drizelles. In Cornwall they are caught in January and February, and their favourite haunts are about the margins of the rocky valleys of the ocean.

The Ling is exceedingly prolific, and has a most voracious appetite; no fish is able to get anything in its way that has life, and the prey is swallowed whole, so that no great art is required to catch it. It is tenacious of life, and survives great injury. Mr. Couch says he once saw a Ling that had swallowed the usual large hook, shaft foremost, of which the fisherman had fastened the line round the tracks of the fish, and when it turned round, entered the opposite side of the stomach, and opened the organs together in complicated folds; yet having escaped by breaking the line, it survived to swallow another hook, and was taken several days after.

The most usual length of the Ling fish is from three to four feet; Pennant mentions having heard of one which measured seven feet; and Mr. Couch has known them weigh 70 lbs.

The body of the Ling is slender, more elongated than that of the Hake; roundish; head flat; gape large, lower jaw shorter than the upper, with a single barbule at its extremity; teeth in the upper jaw small, and very numerous, those in the lower jaw longer and larger, forming but a single row; lateral line straight, scales small, firmly adhering to the skin; two dorsal fins of equal height, the first short, commencing near the head, not pointed as in the Hake, but with most of the rays even; second long, immerses itself, reaching the caudal fin, the posterior portion the most elevated; vent in a line with the eighth or ninth ray of the second dorsal fin; the fin immediately behind it is long, resembling the second dorsal fin, and terminating on the same line with it; caudal rounded at the base, and slightly emarginate in front, and blackish in colour; sometimes cirrhus without the olivaeeous tint; belly silvery; ventrals white; dorsal and anal edged with white; caudal marked near the end with a transverse black bar; the extreme tip white.

*L. vulgaris.* The Burbot, or Ele-Pont, is the only British species of this numerous family of fishes that lives permanently in fresh water, and prefers in this country slow running rivers; but it is neither so generally known, nor so much frequented, as from its flesh it deserves. It is said to be found in various parts of the north of Europe, Siberia, Asia, and India. In this country it is rather local. It occurs in the Cam, and in several of the rivers of Norfolk and Lincolnshire. The Trent produces it, and Nottingham market is occasionally supplied with samples for sale. The Burbot is not unlike the eel in some of its habits, concealing itself under stones, waiting and watching for its prey, which consists of aquatic insects, crustacea, small fish under arches, into which such small and weak animals are likely to be brought by the current of the water. It feeds principally during the night, and the light, is most often caught by trimmers and night-liners. The Burbot is sometimes called the Cow-fish, from the manner of its swimming, hunching itself up, as the eel does also. In this country it has been known to attain the weight of 45 lbs., but a common weight is about 2 lbs.

The flesh is firm, white, and of good flavour, and is some considered superior to that of the eel. As the Burbot is extremely hardy, it might be increased in any quantity, which would amply repay the labour and cost of the experiment. It would thrive well and multiply in large lakes. The length of the fish is from one to two feet; the head depressed, smooth; jaws equal; chin with one barbule; the gape large, with small teeth above and below, small scales on the upper jaw; gill-opening large; the length of the head as compared to that of the body of the eels is as one to four; the form of the body cylindrical, compressed posteriorly; the first dorsal fin is small and rounded, the second dorsal fin with 13 rays, the anal fin nearly uniform in height; ventral fins placed very forward, narrow, and pointed; the pectoral fins large and rounded; the anal fin begins on a line behind the commencement of the second dorsal fin, but ends very nearly on the same plane; the tail oval and slightly pointed; the body yellowish-brown, clouded and spotted with darker brown, and covered with a mucous secretion; under parts lighter; the lateral line indistinct and straight; scales small; the fins partaking of the colour of the part of the body from which they emanate, those of the lower series being much the lightest. (Yarrell, British Fishes.)

LOTUS, a genus of Plants belonging to the natural order Liliaceae, which contains four species annuals, each with a keel ascending with a narrowed point; the wings are convergent at their upper margin; longer filaments dilated upwards; style knotted at the base, filiform, subulate; pod linear; many-seeded, 2-valved, imperfectly divided by transverse partitions.

*L. corniculatus.* Common Bird's- Foot Trefoil, is found in pastures and on dry banks in Great Britain. The claw of the standard is obvate, transversely vaulted; calyx-teeth straight in the bud, subulate from a triangular base, heads 6-10-flowered. The plant is glabrous or slightly hairy; stem ascending; leaflets oblongate; stipules ovate; angle between the two upper calyx-teeth rounded.

*L. angustifolius.* This is the round of the standard linear; calyx-teeth spreading like a star in the bud, subulate from a triangular base, two upper ones diverging; heads 8-12-flowered; leaflets obvate; stipules roundish ovate.

*L. angustissimum* is found in the south of England, near the sea. It has the claw of the standard linear; calyx-teeth straight in the bud, subulate; pod linear eight times longer than the calyx; beak straight; head about 5-flowered.

*L. glutinosus* is found near the sea in Devonshire and Cornwall. It has the claw of the standard subulate; calyx-teeth straight in the bud, subulate; pod rugose, terete, twice as long as the calyx; beak elongate, sessaceous, bent downwards; heads few-flowered; leaflets obvate-lanceolate; stipules have persistent basal laminae. There are many European species of this genus, none of which are of any importance.

LOUGHOR. [GLAMORGANSHIRE.]

LOUIS PHILIPPE, King of the French, Duc d'Orléans and Chartres, and Count de Neully, was the eldest son of Louis Philippe Joseph, Duc d'Orléans, the Philippe Égalité of the Convention [Orléans, House of], and Louise Marie de Bourbon, daughter of the Duc de Penthièvre.

Louis Philippe was himself born at Paris, October 9th, 1773. His youth was marked by the spirit of benevolence, and the judicious teaching of Madame de Genlis was well calculated to draw out the good qualities of those who were brought up under her charge. In his infancy he bore the title of Duc de Valois and afterwards of Chartres. In 1792 he was the young Duc de Chartres, having been nominated to the colonelcy of the 14th regiment of dragoons, assumed the command of that corps. It is said that almost his first act of authority was the rescue from the fury of the mob of this same corps, and he was rewarded by that time exacted by the government from all ecclesiastics. On this occasion he showed great tact and presence of mind, and subsequently received the honour of a civic crown from the mob itself. He was made a general and an engineer of that place, from drowning. By these means he became popular among the French people. In August 1792, the young duke quitted Vendôme command of his regiment for Valenciennes. Whilst he was stationed there, he was proclaimed against Austria, and in the April following...
he entered on his first campaign. He fought his first battle at Valmy on the 30th of September, and on the 6th of November was again engaged under Dumourier at Jemappes. At this period the Revolution was rapidly advancing to the crisis. France was nearly exhausted, and had been passed (October 1792) against the Bourbon race; and though his father, the Duc d'Orléans, had renounced his titles and had been enrolled as a citizen under the name of Philip Égalité, his parents and Comte de Beurnonville, retired from Paris, where, having been made the dupe of the revolutionary party, and having voted for the death of Louis XVI., he was dragged to the scaffold in his turn, January 21, 1793. For seven months after this date the young duke remained at his father's seat, the Château de Meudon. The Committee of Public Safety summoned before them both the Duc de Chartres, and his faithful friend Dumourier. Aware of the sanguinary character of the tribunal before which they would have to plead, he at once resolved to make their escape into the Netherland, then in possession of Austria. The Austrian authorities gladly received the fugitives, and even offered to bestow on the duke a commission in their army; but he refused to take up arms against his country, and retired into private life. In April he set out disguised as an English traveller, on a tour through Germany, and journeyed through Liége, Aix-la-Chapelle, Cologne, and Coblenz, towards Switzerland. The resources at his command were very limited, and he soon arrived in the north-west. His sister Adelaide, known in history as Madame Montes Hellé d'Orléans, at the same time fled the country together with Madame de Genlis, and met her brother at Zurich. The authorites of that canton, in fear of the French government, deprived the duquesse and her companion of the abode in Zoug; but being discovered, the duke placed his sister and Madame de Genlis in the convent of St. Claire, near Baumberg, adopted the disguise of a traveller, and started on a fresh journey of danger and adventure.

His first stop was at Gotz, where he received from M. de Montesquieu the offer of a post as professor in the college of Reichenau, close by the confines of the Upper and the Lower Rhine. He at once offered himself for examination. The examination was held in the Château de Chasaed, in October 1793. Here he remained eight months, during which he was engaged in lecturing on mathematics and geography. At this time he accepted the friendly offer of M. de Montesquieu of an asylum at Baumberg, where he remained in concealment till the close of 1794. His retreat being again discovered, he next went to Hamburg, in the hope of being able to procure a passage to America; but being disappointed, he crossed over via Copenaghen to Copenhagen and to London, where he remained almost entirely on foot, as far as the North Cape. Meantime the course of circumstances at Paris had changed, and the Directory became anxious to compromise matters with the Orléans family, by procuring their voluntary removal to America. They agreed to it, and the young prince returned to Paris, and the Comte de Beaunoin, who had been thrown into prison as dangerous subjects, and at the same time in order to procure the restoration of his mother's estates which had been confiscated, Louis Philippe (whom we shall henceforward term the Duc d'Orléans) accepted a passage to the United States, and having left the Elbe in September 1796, reached Philadelphia, where he was joined by his two brothers. The next year the three brothers spent in the United States, and toured the western portions of the States. In the course of this excursion, the duke gained great repute for his medical skill, by the facts of a vein in his arm in an attack of fever. He afterwards performed the same operation for an Indian chief, in revenge of an injury, which was allowed to pass the night upon the large rug at the feet of the wild sovereign and his relatives. Having made the acquaintance of Washington at Mount Vernon, they returned to Philadelphia, whence they proceeded to New Orleans, and thence to Havana, where they were received with respect, or even with civility, they went on to New York, and crossing to England in a sailing packet, they landed at Falmouth in February 1800. The royal exiles were welcomed in London by the King, the Prince of Wales, Lord Georgeville, the Marquis of Hastings, and the leaders of the politics and fashion of the day. An Orléans mania prevailed through London, and an invasion of France to effect the restoration of the Bourbons was even talked of. After a short time the brothers settled at Twickenham, in a house formerly occupied by General Pollock, and since known as Orleans House.

The Duc de Montpensier, whose health had long been declining, died at Twickenham in May 1807, and was buried in Westminster Abbey. Soon afterwards the health of the Duc d'Orléans also began to decline, and in March 1810 he was urged to retire to Palermo. It so happened that Ferdinand, king of Naples and Sicily, was dwelling in that city under the protection of the British flag, while Murat occupied his throne in Italy. During his absence the Duc d'Orléans had made friends with the Princess Amelia, the second daughter of the king, to whom he was married November 25, 1809. For upwards of four years the Duc d'Orléans resided at Palermo without taking any part in the public affairs of Europe, if we except a visit which he paid to Spain in 1810, in the illusive idea that negotiations commenced by the Spanish and English authorities might eventuate in an offer on their part to entrust to his hands the regency of that country.

In 1814 he witnessed the fall of Napoleon I., and of the intended restoration of the Bourbons. The duke returned to Paris without delay, and was re-instanted in his honours and military rank. The return of Napoleon in the early part of the following year again disturbed the peace of the country. The Orléans family to England for safety, the duke took the command of the army in the north in obedience to the orders of Louis XVIII. Rather than endanger the peace of France by family feuds, he resigned his command in the following March, and retired to Twickenham, whence he returned to Paris after the Hundred Days, in obedience to a decree compelling the attendance of princes of the blood in the Chamber of Peers. He conciliated the popular esteem and respect by his acquiescence in the changes and political measures. Louis Philippe, in his place in parliament, publicly protested against the extreme measures proposed by the government against those who had taken part in the revolution, and procured their rejection. Louis XVIII., who regarded him with especial favour, in disguise and revenge, forbade princes of the blood royal to appear in the Chamber of Peers. The Duc d'Orléans revenged himself upon the court by entering his son in one of the public colleges as a commoner citizen—"le Diable de Twickenham." He continued to live in privacy at Twickenham during the remainder of that king's life and the first few years of the reign of Charles X. He did not return to France until 1827, when he took up his abode at the palace of Neuwilly, where he continued to reside until his death. The political revolution which occurred which ended in his elevation to the throne as King of the French. Charles, whose weakness and duplicity were his ruin, was now in effect discarded; and the cause of the elder branch of the Bourbons being pronounced hopeless, the struggle of the three days of July was followed by a provisional government, in which Lafayette, Lafayette, Thiers, and other politicians, took the lead. They naturally turned to the Duc d'Orléans, and in the name of the French crown, the crown. The crown was formally accepted by the Duke of Orléans, who was allowed to pass the night upon the large rug at the feet of the wild sovereign and his relatives. Having made the acquaintance of Washington at Mount Vernon, they returned to Philadelphia, whence they proceeded to New Orleans, and thence to Havana, where they were received with respect, or even with civility, they went on to New York, and crossing to England in a sailing packet, they landed at Falmouth in February 1800. The royal exiles were welcomed in London by the King, the Prince of Wales, Lord Georgeville, the Marquis of Hastings, and the leaders of the politics and fashion of the day. An Orléans mania
of the 'Napoleon of Peace,' as Louis Philippe liked to be called. His reign was a period of corruption in high places, of internal restriction to the press, and of a fraudulent and heartless policy towards the allies of his country, whose goodwill he more especially forfeited by his over-reaching conduct in regard to the marriage of the Duc de discs, and whose support during the Crimean War he pass that the heart of the nation became alienated from his king; and when a trifling disturbance in February 1848 was aggravated into a popular riot through the audacity of a few ultra-republicans, Louis Philippe felt that he stood alone and unsupported by the king, his land abroad, and that the soldiers were his only means of defence. He shrank from employing the bayonets against his people: he fell in consequence, and his house fell with him. The king fled in disguise from Paris to the coast of Normandy, and took refuge with a safe regent, his son, to a land, to which his family had already made their escape. He landed at Newhaven, March 3rd, 1848. The Queen of England—who, in 1848, had enjoyed the hospitality of Louis Philippe at the Château d'En, his royal residence near Dieppe, and who had entertained him in the following year at Windsor, and conferred on him the order of the Garter—immediately assigned Claremont, near Esher, as a residence for himself and his exiled family. From the time of his arrest, his health began to decline; and he died on the 26th of August 1850, in the presence of Queen Amelie and his family, having dictated to them the conclusion of his memoirs, and having received the last rites and sacraments of the Church at the hands of his chaplain. He was buried in the Catholic church of Christ Church, at Weybridge, Surrey, and an inscription was placed upon his coffin, stating that his ashes remain there, "donec Deo deambulante in patribus avitos inter cines transfer," etc.

LOUVAIN. [HALORIAN, S. 82.] LOWESTOFFE, or LOWESTOFT. [SUFFOLK.]

LOUCLASE, a Mineral belonging to the anhydrous aluminates of Alumina. It has nearly the form of Felspar, but is distinguished by a cavitous or pustulose substance on the diagonal. It contains 6 per cent. of soda and 3 per cent. of potash. It is found at Hammond, in the state of New York, in company with Fyroxene, Graphite, and Calcsap.

LOYDIA, or LOYDIA, a genus of Plants belonging to the natural order Liliaceae. The perianth is persistent and patent; stamens inserted at the base of the perianth; anthers erect; style filiform; stigma trinervig.; seeds angular above, flat beneath.

L. serrata is a native of Welsh mountains. It is a rare plant, but is found on Mount Snowdon. The root-leaves are semi-cylindrical; stem-leaves dilated below and sheathing; flowers mostly solitary, nectary a transverse plate. The height is 5 or 6 inches. Stem and leaves springing separately from the root, stem may of theใบpetals not several, short; flowers white, with reddish lines internally.

LUCANIA, a province of ancient Italy, bounded N. by the Silarus, the Apenines, and the Bradanus, which separate it from Campania, Samnium, and Apulia respectively; E. by the Gulf of Tarentum, along which it extended to the mouth of the Crathis; S. by Bruttium; and W. by the Tyrrenian Sea, between the mouths of the Laus and Silurus. The territory of Lucania is now comprised chiefly in the modern provinces of Basilicata, portions of it are included in Calabria and Principato Cita. Under these heads the physical geography of the country is given, and many particulars respecting its ancient towns. The rivers that fall into the Gulf of Taranto in the Bradanus were—proceeding from the north, the Caesuvum, the Aca- landrus, the Acitra, the Siris, and the Sybaris. These rivers rise in the mountains that cover all the interior of the province, and run generally in the direction of east by south across a very fertile plain, which skirts the shore of the Tarentine Bay. Along this shore were several celebrated cities founded by early Greek colonies: Metapontum, between the mouths of the Bradanus and the Caesuvum; Herculaneum, near the mouth of the Acitra, and on its left bank; a little higher up the right bank was Pandoeis; Siris, near the mouth of the Siris and on its left bank; Sybaris, near the mouth of the Sybaris; and Thurii, a few miles higher up, in the plain between the Crathis and the Sybaris. On the coast of the Tyrrenian Sea, between Pandoeis and Sybaris, a few miles more, and near the coast of the Silurus and Eela, or Velia, further south, on the Bay of Eela, and a few miles north of the promontory of Palmarina.
L. Binduca is a native of Hindustan. It is a climbing discicious plant; the leaves are toothed and 5-angled. Male flowers in racemes. Female flowers solitary; fruit round, ovoid, and long, ciliate bristles. It is considered in northern India a powerful in cases of dropsy. The English are partial offenders of the natives of India, and are esteemed very wholesome.

LUG-WORM. [AZEMOSSA, S. 2] LUMINOUSITY OF ORGANIC BEINGS. Organic bodies, under certain conditions become luminous, and upon the supposition that this is due to the partial combustion of phosphores at a low temperature, the phenomenon has been called phosphorescence. This luminosity is very constantly developed under the same circumstances in Lucifera and other species of this order. The decomposition of the bodies of plants and animals as well as whilst they are still living. The oldest observations on this subject were made on the wood of trees whilst in a state of decay. This however takes place only under peculiar circumstances. It generally occurs when the wood of trees is buried in the earth whilst they are in a green state, and does not take place when wood is allowed to decompose in the usual way and in free contact with the air. It is also observed that it takes place when the wood is allowed to decompose in a dry place. When exhibiting this property will retain it for a long period when kept in a dry place. Albrecht observed luminosity in a tree during the night at a spot where one of its branches had been cut off, the air being still appearing like smoke and enabling us to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wounded, the juice frequently becomes luminous, whilst it is descending the sides of the tree. The cause of this phenomenon in plants is unknown, but it is probable that the transparent fluid of the tissues attended with a union of oxygen gas, but what determines the development of light under these more than other circumstances is still unknown.

In living plants luminosity has been frequently observed. It is most constant amongst some forms of fungi, especially of the genus Rhizomorphs. In the coal-mines of the vicinity of Dresden the species of Rhizomorphae are so numerous as to "dazzle the eye of the brilliant light they afford." [Braune, S. 1.] The light from decaying wood, as also from the living Rhizomorphae, continues although they are immersed in insipratable gases, ligneous, hydrophoric acid, oxygen, &c. The phenomenon in both the living and the dead plants is probably due to the same cause.

Another class of plants in which light has been observed is the Mosses. Several species of the genus Schistozoa, which grow in caverns and other damp places, have been observed to give out light. Mr. Babington and other botanists, as well as E. Copitz, have conned the mosses of Funk, Brandenburg, Nees von Esenbeck, Hornschuch, Strove, Unger, Bridel-Briderei, and Agardh, have observed it on the continent of Europe. The two latter attributed this light to a small alga, which Bridel-Briderei called Colopneuris Lemnysmus, and Agardh called Protococcus Lemnysmus, which they supposed was parasitic on the moss. Unger however has examined the moss accurately, and finds that at certain seasons the satellites of this moss assume a globular form, and being partly transparent, the light is refracted and reflected in such a way as to present a luminosity on the surface of the vesicles.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation that I made of this phenomenon was made on a flower of the daughter Christina Linne. She was walking in the garden one hot summer's evening, when she observed the flowers of Tropotomus majus to give forth a stream of light. This was attributed by many to an optical illusion, but the fact has since been repeatedly observed on this as well as other plants. We are not perhaps in a position to say this was not an optical illusion; but if it was, one would expect that it should be more constant. It has also been seen by several others, but which I have not been able to procure. I have seen it, the others have seen it also. A correspondent of the 'Gardener's Chronicle,' October, 1843, says, "I have frequently observed the luminous appearance of garden plants, and I am absolutely sure that I have seen it on the double marigold, and more especially on the Petunia, the hairy red poppy, in my garden in Worcestershire. In the evening after a hot dry day, the flashes of light have afforded me much amusement to myself and others." It is this phenomenon that Coleridge alludes in the following lines:

""Tis saith on summer's evening hour The golden-scorner's flower A fair electric flame.""

Decaying animal bodies frequently emit a luminous appearance, which has generally been attributed to the presence of phosphate of lime in their skeletons, which become decomposed and yield phosphorus when exposed to the action of organic compounds in a state of decomposition. The luminosity of the decaying fish is attributed. But the emission of light is a very constant phenomenon of many of the invertebrate animals under peculiar circumstances. Thus during warm weather, when the sun's rays are not too strong, when the ocean, the waves frequently exhibit a diffused light with here and there a concentration of a brighter light. This occurs in our own climate, but the phosphorescence is much more brilliant in tropical seas. Foppig, in his 'Reise in Chili, Peru, und auf dem Amazon-strome,' describes this phenomenon in an equatorial sea.

"While the north side of the vessel is still illuminated by the last fading rays of the evening sun, and the opposite side darkened by the shade of the sails, the sea in this direction already becomes brilliant. One spot after another begins to be illuminated, illuminating with light coming from greater depths, till at last, with the approach of night, a new creation seems to be called into existence. These illuminated beings move in various directions, sometimes appearing as if they were preparing to strike at others darting through the dark surface of the water like a rapid flash of lightning. A great number of these beings are undoubtedly true night-animals which conceal themselves during daylight in the dark depths of the ocean.

These lighted fish are principally produced by various species of the family Acalephæ. [Acalepha; Pulmoidea.] The light emitted by these animals seems to be due to the secretions on the surface of their bodies, for when this secretion is removed it retains for some hours its luminous character, and will even impart it to milk or water. But this property is not confined to the Acalepha. Many species of Polyopera, some of the Echinoderma, and the lower forms of Molusces also exhibit this appearance. Some few of the Crustacea and even Fishes have been observed to possess the same property.

Amongst insects this phenomenon is not uncommon. Those which possess the greatest luminous power belong to the Coleoptera, the Beetle-Tribe, and of these the two families represented by the Fire-Fly—the Eleutheria—and the Glow-Worm—the Lampyrida, are the most distinguished. [Eleuthera; Lantimida.] Some of the species of the tribes of Myriapod and Amneida give light occasionally, as the Centepede and Earth-Bugs. (Meyer; Pflaumen-Physiologie, band ii.; Carpenter, Animal Physiology; Lancaster in Gardeners' Chronicle, 1843.)

LUNACY. The statutes mentioned under this head [Lunacy, S. 1, p. 225] have been to some extent repealed, and their administrative provisions have been consolidated and amended by the Lunacy Regulation Act, 1853, 16 & 17 Vict. c. 70, by which the proceedings of the Court of Chancery in the care and custody of lunatics are now regulated. The Lords Justices of the Court of Appeal in Chancery have the same jurisdiction in matters of lunacy as the Lord Chancellor, and by them indeed are proceedings in such matters now usually disposed of.

LUNACY (SCOTLAND). The previous statutes regulating the care and custody of lunatics in Scotland are repealed, and the whole law on this subject consolidated and amended by the statute 20 & 21 Vict. c. 71.

LUNGS. The development of the lungs has been recently investigated, and the following is Kölliker's summary of what is known:

"In the Mammalia the lungs appear a little after the liver, in the form of two hollow protrusions of the anterior wall of the pharynx, which are in close apposition, and soon become furnished with a complete covering of the larynx and trachea—and in the composition of which the epithelial tube and the fibrous membranes of the intestines take an equal share. In the further course of development there springs from the extremities of the original protrusions a complex system of bronchi, which issues in the lungs, by such processes, which differ entirely in what may be observed in most other glands. From their first formation they are always hollow, and in the sixth month the air-cells are developed.
from their invariably clavate dilated extremities. During this growth of the glandular elements the interior epithelium extends downwards, forming the thickenings of the multilocular cells (probably by division), whilst at the same time the fibrous layer surrounding them also grows, and finally constitutes the fibrous membrane of the bronchi and air-cells, together with the vessels and nerves. In the second month in the case of the lungs it becomes well formed; and besides them smaller divisions also, 0.16" in size, may be recognised, originating in the dilated extremities of the bronchi, which even at this time are considerably ramified. As development proceeds, ramifications of one bronchus are multiplied; these gland-granules, as they are termed, become more and more numerous, and ultimately in the fifth month, are aggregated so as to form smaller lobules of 0.25"-0.45" in size, each of which is filled with the first inspiration, 0.03"-0.04"-0.06"; the latter at this time appear to exist in the same number as in the adult, the further increase of the lungs proceeding only from the expansion of all its parts by the growth of the lungs," continues the translators of Kööller, "presents no real difficulty, except in one point; that is, with respect to the relation of the pulmonary cells to the terminations of the bronchi, but here the difficulties are very considerable. In recent preparations it is obvious that the air-cells communicate in many ways, and in any case that they are not merely terminal on the extremities of the bronchi. If it be desired to investigate the whole subject, inflated and dried lungs (it is better in air) are used, and on an end it is cut by itself, or corroded preparations, or lungs injected with uncoloured substances (wax and resin), are most suitable; and with such a definite result will be obtained, after a series of observations. Before the injection of the bronchi is completed, the injection of the air should be the same, tho less conveniently, a well-fitting syringe may be employed. The injection of the blood-vessels is readily effected, and the preparation should be kept moist; sometimes when injected dry by itself, the processes of Schröder and Haring, with transparent substances (Prussian blue, &c.), dried preparations are to be preferred. The air-cells and bronchi, the larynx and trachea, are readily examined. The epithelium is obtained in thin sections through the lung, as well as clissated cells. If it is wished to study the alveoli, the air must previously be carefully removed. These are best displayed in man, in whom also other parts such as cartilage, elastic elements, muscles, and glands, are easily obtainable."

(Kööller, Manual of Human Histology, translated for the Sydenham Society by Busk and Huxley.)

LYCOPODIUM. [Convar. S. 2.]

LYCOPODIUM, a genus of Plants belonging to the natural order Solanaceae. It has an uncolate calyx regularly 5-toothed, or irregularly 3-5-cleft; permanent corolla funnel-shaped or tubular; limb 5- or 10-cleft, or toothed, imbricate in accilation, sometimes plicate; stamens 6, usually exserted, filaments banded and widened at the base; stigma pellately depressed, or capitellate, bisulcate; berry roundish, 3-celled, propped by the permanent calyx; placenta adnate; seeds numerous, reniform. The species are trees or shrubs usually stiff. Corollas white, yellow, rose-coloured, purple, blue, or scarlet.

L. europaeum has erect loose branches; buds spinescent; leaves fascicled, obovate, lanceolate, obtuse, or spatulate, bluish, glabrous; flowers twin or solitary; corolla funnel-shaped; stamens 6, the filaments being jointed at the base; they are a native of the south of Europe and the north of Africa: in the Grecian islands common in hedges, but scarcely indigenous. The calyx is 5-cleft, ruptured at the side: the corolla pink, or vinwarded with red veins: tube greenish. Clarius says that the young shoot are eaten in Spain with oil and vinegar.

L. barbatum has dependent branches; buds spiny; leaves lanceolate, flat, glabrous, acut; flowers twin, extra-cauline, bluish, glabrous; pollination by insects equal in length to the limb. It is a native of the north of Asia, Africa, and south of Europe. There is a variety hairy pale corollas and yellowish-red berries.

There are about 30 species of this genus described, most of which are found in the forests of India. They are commonly known by the name of Box-Thorn.

LYCOPODIUM, a genus of Plants belonging to the natural order Lycopodiales. It has 1-celled 2-valved capsules, containing 2 seeds, and a large prostrate root.
LYCOPUS, a genus of Plants belonging to the natural order Labiata. It has a 4-fld corolla, scarcely longer than the equal 5-toothed calyx; stamens 2; anther-cells parallel or subitimately divergent; 2 upper stamens wanting, or rudimentary, or rarely perfect.

L. Europaeus inhabits wet ditches and sides of ponds, and is known popularly under the name of Gipsy-Wort, because gipsies are said to stain their skins with its juice. It has stalked ovate-oblong leaves, glabrous or pubescent, opposite. Flowers small, in dense whorls. It is found on banks of streams and ditches in Great Britain.

LYDD. [Kavr.]
written on botany, geology, and zoology. Though a list of Dr. Macgillivray's works would alone occupy a large space, yet he was not a man of the closet. Though one of the most diligent of compilers, he was a laborsious original investigator. Whilst he lived by natural history as a profession, he pursued it both in theory and in practice, and in which it afforded towards the necessities of existence, he rendered a large amount of observation made with great labour and self-sacrifice. Although naturally an amiable man, he has frequently in his works—as is often the case with men of the ardent character—expressed himself strongly on the views of others, and in this way he made many enemies during his life. Now that the grave has closed over him, even those with whom he most differed will be heard only to admire."

MACHAIRIUM, a genus of Plants belonging to the natural order Leguminosae. One species, M. Schomburgktii, produces the Inaka Wood of Guyana, remarkable for its brown and black streaks, on which it is employed in cabinet-work.

MACHYNLEETH. [Montgomeryshire.]

MACLURA, a genus of Plants belonging to the natural order Moracese. The fruit of M. aurantiaca, the Osage Orange, is as large as the fist, orange-coloured, and filled with a yellow fleshy alime, with which the native tribes smear their faces when going to war. The wood of M. tinctoria is the dye-wood called Fustic; it contains Morine, a peculiar colouring substance; its fruit is pleasant; and used in medicine. In medicine it is employed for the same purposes as the black mulberry in Europe. According to Martius, both the other species of the genus yieldustain in Brazil. (Lindley, Vegetable Kingdom.)

MACROCYSTIS, a genus of plants belonging to the natural order Lepidocarpaceae, and the tribe Laminaceae. The enormous fronds produced by M. pyrifera have been spoken of by many navigators. They appear to be from 500 to 1800 feet in length; the leaves are long and narrow, and at the base of each is a vesicle filled with air, without which it would be impossible for the plant to support its enormous length in the water, the stem not being thicker than the finger, and the upper branches as slender as common packthread. This plant was seen by Dr. Joseph Hooker in 61° 8' S. and 12° 43' W. in vegetating patches wherever the water was free of ice-bergs.

MACROPITERYX. [Night-Jars.]

MACROGLOTTIS. [Chiropter.] A genus of large bats.

MACROOM, county of Cork, Ireland, a post and market-town, and the seat of a Poor-Law Union, is situated on the river Sullane, and on the road from Cork to Killarney, in 61° 56' N. lat., 8° 56' W. long., distant by road 244 miles W. from Cork, and 1634 miles S.W. from S. from Dublin. The population is 3757, in 789 houses. The Macroom Poor-Law Union comprises 25 electoral divisions, with an area of 179,108 acres, and a population in 1851 of 37,394. The town consists principally of one street nearly a mile long, and is in great part by cabins and other mean dwellings. Near the market-place are some shops. The parish church, the Roman Catholic chapel, the sessions-house and bridewell, and a market-house, the dispensary, and the Union workhouse are the public edifices. Petty-sessions are held monthly. Fairs are held on the 13th day of May, July, September, and November. There is a large weekly market. Macroom Castle is a fine old structure overhanging the river.

MACROPUR, a genus of Plants belonging to the natural order Pterocarpaceae. M. mephitis, the Avr., is the most celebrated of the narcotic Pepper-Worts. It has a dextro acuminate many-nerved leaves; solitary axillary spikes, very short, pedunculated, and spreading. The rhizome is thick, woody, rugged, and aromatic. It is used in tincture against chronic rheumatism. Macerated in water it forms an intoxicating beverage, of which the Obetahians make use as a medicine; they make themselves drunk, after which violent convulsion of the stomach."

MACRORHINUS, [Sagal.]

MADATUES. [Chiropter.]

MADELEY. [Chiropter.]

MAES. [Mae., S. E.]

MAGENDIE, FRANCOIS, a distinguished French physician and physiologist. Although his father practised as a physician in Paris, he was born at Bordeaux on the 15th of October 1783. He was soon after brought to Paris, where he had the misfortune to lose his mother. His father took an active part in the revolutionary movements of the period, was mayor of the 10th arrondissement, a member of the Hospital Council, and of the Comunes de Paris. He also encouraged his son to take an interest in the study of anatomy and neglect of his child, who is said not to have been able to read at the age of ten. He was however then sent to school, and at the age of fourteen had achieved such success that he was rewarded with a prize at the annual concours. Through his father's influence he was appointed a headmaster of a school and boy, and afterwards his demonstrator of anatomy. At the age of twenty, after an examination by concours, he was appointed aide d'anatomie (prosector) in the Faculty of Medicine of Paris. A few days after his appointment he occupied the chair of the new position he devoted himself enthusiastically to the study of anatomy, but he was induced by Dupuytren to give up this branch of the medical art, and devote himself to the practice of medicine. He was subsequently appointed physician to the Hotel Dieu. In 1819 he was elected a member of the Academy of Sciences; he was also a member of the Academy of Medicine, and in 1831 he succeeded Professor Recamier, who had resigned on the accession of Louis Philippe to the throne of France, in the chair of anatomy in the College of France. Professor Magendie was a laborious writer as well as one of the most illustrious physiological experimentalists and discoverers. His larger works are as follows:—1, "Formulaires pour la Préparation et Emploi de Plantes nouveaux Médicamenteuses," published by the Paris Government in 1828. It was speedily translated into all the languages of Europe. It contained an abstract of the action of these potent active principles found in plants, which had at that time been introduced into the practice of medicine, more particularly by the French chemists. The work included such remedies as morphine, strychnine, prussic acid, and others, on the operation of which an animal system Magendie had successfully experimented. 2, "Prix Élémentaire de Physiologie," published in two volumes at Paris in 1816-17. It went through several editions, and was afterwards entitled, "Éléments de Physiologie." It was translated into German and English, and for many years it was one of the best manuals on physiology for the use of students. 3, "Leçons sur les Phénomènes physiques de la Vie." These were a series of lectures delivered at different times, and collected together by M. J. James, and published in 1836-41. These were also translated, though not very accurately, into German. 4, "Leçons sur les Fonctions et les Maladies du Système nerveux." These were also lectures delivered in the College of France, and were published in two volumes in 1839. 5, "Leçons sur le Sang." These lectures on the physiology of the blood were included in the "Essais philosophiques et cliniques sur le liquide cephalo-rachidien," by Pierre, Paris, 1842. In addition to these larger works, Magendie published a large number of papers, which will be found scattered in the "Comptes Rendus," and was a contributor to the "Journée de Physiologie expérimentale," a periodical which he started in 1821, and which he continued to edit for ten years. He was also a contributor to several of the Dictionaries which appeared in France during the commencement of the present century. He wrote for the "Dictionnaire de Médecine et de Chirurgie pratique," the "Encyclopédie des Gens du Monde," and the "Dictionnaire de Médecine utile." Although Magendie retained the generalizing power which he had displayed him at the head of European physiology, he was most industrious in the performance, and ingenious in devising of physiological experiments. It was as an experimenter that he produced a lasting impression on the progress of physiology. In fact, no numerous were his experiments one time on living animals, that the authorities is France thought it necessary to interfere. Some of the results of his physiological enquiries are too important to be passed over in this notice:—He successfully demonstrated what had been only suspected by previous physiologists, that the veins were organs of absorption. His experiments on this subject have been regarded by physiologists as setting the question at rest, and proving that the veins are the great agents of absorption of the blood.

2. His numerous experiments on the absorption of poisons led to a more accurate apprehension of the nature of their action on the human system. He first demonstrated that
strypnia acts upon the spinal cord, and destroys by paralysis the nerves of respiration, thus inducing apoplexy.

4. He investigated with great care the action of hydrocynous vapours on the nervous system, and directed attention to its value as a remedy in certain forms of a rising from irritation in the lungs.

5. Long before the chemical nature of food was understood, Magendie pointed out that non-nitrogenous foods were innutritious and injurious. This was the result of a long series of experiments on the feeding of the lower animals.

6. He performed a series of experiments on the admission of air into the veins, and showed how likely this was to be a source of death, in operation.

7. Magendie, with Sir Charles Bell the honour of having discovered the real functions of the spinal nerves. Walker had demonstrated the existence of two roots to the spinal nerves. Bell showed that the nerves performed two functions, that of sensation and volition, and that these were sometimes separate, but the final demonstration of the two roots of the spinal nerves being devoted to the separate functions, seems to have been first clearly established by Magendie.

To these more important discoveries and investigations must be added a large number of experimental researches upon the functions of the brain, its parts and nerves. If these did not lead to immediate and decisive results, they have helped to prepare the ground for others that have since guided to more correct conclusions.

Magendie was a Commander of the Legion of Honour, and few men gained more of the respect and confidence of the government in matters of public health, whilst amongst the medical profession he was the result of a long series of experiments on the feeding of the lower animals.

As a result of his great talent and original genius. He died on the 8th of October 1855.

MAGHERAFLET. [London.]...
ship. Selecting from the vast and still then imperfectly explored manuscript treasures of the Vatican, he prepared his 'Classici Scriptores ex Codicibus Vaticanis editi,' a vast series of ten 4to volumes (Rome 1825, and following years), on the plan of the various 'Anecdota,' published under different titles by Mabillon, Pay, Mazaras, Muratori, and others. It is a work of immense labour and research, destined for generations of scholars. It contains a vast amount of Latin, sacred and profane, theological, historical, patrimonial, and philosophical. One of the volumes, the second, is perhaps the most curious of the entire, containing considerable fragments, recovered from a vast variety of manuscript sources, including the ancient Roman historians, Polybius, Diodorus Siculus, Dionysius of Halicarnassus, Dion Cassius, Appian, Dionysius Eusebius, and others.

The 'Vaticana Collecta' was quickly followed by a similar collection in ten volumes, 8vo, 'Classici Scriptores ex Codicibus Vaticanis editi,' completed in 1838; which included some of the editor's earlier publications (especially the 'De Republica'); although, with the exception of about two volumes, its contents are entirely new. While he was engaged in the publication of this series he held the labours and responsible post of secretary of the Propaganda, to which he had been appointed in 1833; and it was observed with wonder that his extensive literary engagements never were found to interfere with the demands of his official duties. His active and business-like habits, the promptness of his decisions, and the prudence and discretion of his whole administration, are still gratefully remembered by the members of the various missions under the surveillance of the Propaganda.

After five years of service in this laborious office, he was named (1838) cardinal, at the same time with his friend and successor in the Vatican Library, Morsalfari; and soon afterwards was appointed to several important and coveted offices in the Roman court, chiefly of a literary character. He was named successively Prefect of the Congregation for the Supervision of the Oriental Press; Prefect of the Congregation for Catholic Education and Propaganda; and eventually the Council of Trent. In 1853 he was appointed to the still more congenial post of Librarian of the Roman Church.

This elevation did not interrupt in the slightest degree the literary labours in which he had been engaged. Scarcely was the collection of 'Classici Anecdoti' completed when he commenced a similar one, also in ten volumes, 8vo, 'Spicilegium Romanum' (1833-44), equally interesting and various in its contents, and a fourth collection entitled, 'Notitiae Christopholicae,' published in 1853 in six volumes 4to; but before he completed this, he was called to the duties of a far more extraordinary character, from the circumstance that it was compiled from the mere gleanings which had escaped the researches of the earlier editors and collectors. Several years before, he had undertaken to edit the well-known 'Codex Vaticanus' of the Old and New Testament with various readings and prolegomena. The text of this edition was printed many years before his death, but its publication was delayed in order that it might be accompanied by the intended prolegomena. He died however at Albano, September 8, 1854, in his seventy-third year, leaving this great work still unpublished; and it is much to be regretted that since his death no trace has been found among his papers of the long-expected dissertations which he had intended to prefix to the 'Codex Vaticanus.' It is conjectured either that, engaged by his other manifold editorial occupations, he deferred year after year this anxious and difficult task, or that, dissatisfied with the execution, he in the end destroyed what he had prepared.

Cardinal Mai's abilities as an editor were of the very highest order. While his collections comprise an infinite variety of matter of every age, of every country, of every variety of style, and of every important character, Greek and Latin, he appears equally the master. Whether the subject be theology or history, or law, or languages, or general literature, his learning is never at fault, and his critical capacity never fails. In his examination of problems, and difficulties, he often rises in assigning an anonymous manuscript to its true author, in collecting fragments of the same work and dovetailing them together into intelligible order, in selecting from a host of unknown materials all that is unpublished, and deciding upon the question of its genuineness or its intrinsic value; in a word, in all the thousands of investigations which fall to the lot of a critical editor treading upon untrodden ground, he possessed a skill and acuteness which can hardly be equalled. It is easy to carry account of the vast variety of subjects which engaged him, must be regarded as little short of marvellous.

The private character of Cardinal Mai has been well described as the very ideal of a Christian scholar. Devoutly of the nature of a great humanist, and deeply imbued with a love for the literature for its own sake also, and he was ever foremost in every project for its advancement. He was a member of all the leading literary societies of Italy, and not unfrequently readers at the sessions of some of Rome assembled at all times liberal and indeed munificent; and at his death (reserving to the Vatican Library the right to purchase it at a moderate price) he bequeathed the proceeds of the sale of his noble library to be applied to the benefit of the poor of the city of Rome, and to the foundation of an endowed chair of Biblical studies, erected to his memory in the church of St. Anastasia, from which he derived his title as cardinal.

MAIANTHEMUM, a genus of Plants belonging to the natural order Apocynaceae. It has 4-parted petals, the segments horizontally patent or reflexed, deciduous; stamina 4; style 1; stigma blunt; berry 3-celled; cells 1-seeded.

M. bifolium has a stem with two alternate, stalked, triangular, cordate leaves; the stem is from 6 to 6 inches high; root fibrous; flowers very deep purple; spikes; flowers small; segments reflexed; berry yellow with brown spot. It is found in woods in the north of England.

MAIDENHEAD. [BERKSHIRE.]

MAGNÁS NEPOMŮK, an ingenious Hungarian poet and historian, was born at Pesth on the 15th of October 1776, and was the fourteenth child of a family of eighteen. He received an excellent education at Erlas and Raab, and his father, Count Joseph Mallath, an Austrian minister of state, induced him to enter into the same service, which he was compelled to relinquish after ten years, from increasing weakness of eye-sight. For two years he was forbidden to read and write, and it was during this time that he began to write his poems. The productions of his pen, in poetry and history are numerous. Many of his poems and one of his histories, that 'Of the Religious Dimensions in Hungary,' are in the Hungarian language; most of the others are in German. He translated with success into German the 'History of the Magus' (6 vols., 1828-31), and his 'History of the Austrian Empire' (6 vols., 1834-50), are the most important of his historical works: the latter contains the result of his investigations during a period of eighteen years. Since 1836, when he was chosen and held the office of a counsellor of the Hungarian Chancery and some others at Pesth, was a member of the Hungarian Conservative party, and in his history mentions his own name, along with that of the Magyars. The last of the only two magnates who opposed what he characterises as the violent and oppressive proceedings of the Magyars in forcing their language on the six million inhabitants of the country, whose languages were entirely different. The whole of his narrative of the conduct of the Kosnusz party in Hungary before the outbreak is deserving of attention, as a statement of one side of the question which is little known in England. The results to unfortunate Mallath were most disastrous. Deprived of the posts he held in Hungary by the revolution of 1848, he appears to have been unable to obtain a compensation from the Austrian Government. His literary labours did not prove remunerative, and his fortune gave way under the combined afflictions of poverty, exile, old age, and indigence. The old man, whose productions have earned him a permanent and honourable place in the literature of both Hungary and Germany, was driven by the pressure of extreme distress to drown himself in the Lake of Szenberg in Upper Bavaria, and with him his daughter, who had shared his misfortunes. The pathetic circumstance took place in the early part of January 1855.

MAINTENON. [Eure-et-Loir.]

MALACANTHUS [Labiades.]

MALACHARD. [Reducio Carbonis, Carbante, Carbonis, Carbonate of Copper, Monocarbonate.] Usually in incrustations, with a smooth tuberose botryoidal or stalactitic surface. Structure fine and fibrously fibrous; also earthy. Colour light green; streak paler. Usually nearly opaque. Crystals translucent to transparent, crystals of stalactitic, inclining to and thinning fibrous incrustations alkali, on a cross fracture. Early
varietie doll. 3.5 to 4. Specific Gravity, 4.
Composition:

- Carbonic Acid: 18
- Oxide of Copper: 70-9
- Water: 11-5

Dissolves with effervescence in nitric acid. Decrepitates and blackens before the blow-pipes, and becomes partly a black scoria. With borax it fuses to a deep green globule, and ultimately affords a bead of copper readily distinguished by its copper-green colour and its association with copper ore. It resembles a siliceous ore of copper, Chrysocolla, a common ore in the mines of the Mississippi valley; but it is distinguished by its complete solution and effervescence in nitric acid. The colourless variety is the bed not to be confused with Chryscolla. Green Malachite usually accompanies other ores of copper, and forms incrustations, which when thick have the colours blended, and extremely delicate in their shades and blending. Perfect crystals are quite rare. The mines of Siberia, at Nischtagil, have afforded great quantities of this ore. A mass partly dissolved measured at top 9 feet by 18 feet; and the portion uncovered contained at least half a million pounds of pure Malachite. Other noted localities are Cheesy in France, Sandridge in Shetland, Schwers in the Tyrol, Cornwall, Australia, and the island of Cuba. This mineral receives a high polish, and is used for inlaid work, and also ear-rings, snuff-boxes, and various ornamental articles. It is not much prized in jewellery. Very large masses are occasionally formed in the stones in Russia, which are worked into slabs for tables, mantel-pieces, and vases, which are of exquisite beauty, owing to the delicate shadings and radiations of colour. In the Great Exhibition of 1861 there were magnificent specimens of this material in the shape of doors and vases sent thither by the Emperor of Russia. At Versailles there is a room furnished entirely with tables, chairs, &c., wrought in Malachite, and the same are to be found in other European palaces. At Nischtagil, a block of Malachite was obtained weighing 40 tons. Malachite is sometimes passed off as turquoise, though easily distinguished by its shade of colour and much inferior hardness. It is a valuable ore when worked, but is too seldom smelted alone, because the metal is liable to escape with the liberated volatile ingredients, carbonic acid.

MALACHIUM, a genus of Plants belonging to the natural order Capparidaceae. It has 5 petals; 5 biff or entire petals; 10 stamens and 8 styles; the capsules opening with 5 biff valves.

* M. aquatilum, Water Chickweed, has a decumbent stem, angular, ascending, and covered with glandular hairs; corolate leaves, acuminate, seajile, the lowest one stalked; flowers solitary, the stem petals bipartite, rather exceeding the calyx; capsule exceeding the calyx. It is usually found in wet places in Great Britain.

MAN. In classifying the races of men, it must be remembered that the divisions and subdivisions which we are employed do not resemble those which are used in the systematic classification of plants and animals. When the whole of the species of the vegetable or the animal kingdom have to be arranged, then we divide them into various primary and subordinate groups, which are called Classes, Families, or Orders, Genus, Species, and Varieties. Now Man himself is but a species; he belongs to a subordinate group of a large division of the animal kingdom. Zoologically considered, Man is an animal belonging to the class Vertebrata, the order Mammalia, the sub-order Hominidae, the genus Homo, and species sapiens. The characters of this species as given by Blumenbach have been stated elsewhere. [Man.]

The following is the arrangement of the races of men, with the definitions given by Dr. Pickering, an American traveller and writer, in his work 'On the Races of Men':

a. White.

1. Arabian.—The nose prominent, the lips thin, the beard abundant, and the hair straight or flowing.
2. Abyssinian.—The complexion hardly becoming florid, the nose prominent, and the hair crisped.

b. Brown.

3. Mongolian.—Beardless, with the hair perfectly straight and very long.
4. Hottentot.—Negro features, and close woolly hair; and the stature diminutive.
5. Malayan.—Beard not so prominent in the profile, the complexion darker than in the preceding races, and the hair straight or flowing.
6. Papuan.—Features not prominent in profile, the beard abundant, the skin harsh to the touch, and the hair crisp or curled.
7. Negrillo.—Apparently beardless, the stature diminutive, the features approaching those of the negro, and the hair woolly.
8. Indian, or Telingan.—The features approaching those of the Arabian, and the hair, in like manner, straight or flowing.
9. Ethiopian.—The complexion and features intermediate between the Telingan and Negro, and the hair crisp.
10. Australian.—Negro features, but combined with straight or flowing hair.
11. Negro.—Close woolly hair, the nose much flattened, and the lips very thick.

The most recent writer and greatest authority on the races of men is Dr. K. G. Latham, who, in his work on the 'Varieties of Man in the British Isles,' gives a new system of classification, in which he designates the following:

In the first place, like Cuvier and other previous writers, he adopts but three primary varieties of the human species:

1. Mongoldia. II. Atlantidea. III. Japetidea.

The termination in 'ide' employed here seems preferable to the use of terms such as class, order, family, tribe, or other words which have another use, either in this or other departments of natural history. It must not, however, be supposed that by using these terms any of the varieties of man can be traced up to a common ancestry, so that we could say all the Mongoldia originated from this man, or all the Atlantidea with that man. In tracing back races we have no evidence so conclusive that any particular variety originated with a particular pair of human beings, as we have that all the families of mankind have originated in a single pair. The terms Mongoldia, Atlantidea, and Japetidea are not derived from a community of meaning in the things they express. Thus, the first comes from a nation, the Mongol, who occupied a portion of eastern Asia, and were at one time the conquerors of the world, and are regarded as typical of a large portion of the human race. The Atlantidea are entirely found in Africa; hence their name. The Japetidea include the races of men in Europe, who are traditionally descended from Japheth; hence the name selected to express them.

I. Mongoldia.—The people comprised under this variety have the following physical conformation:—The face is broad and flat, which either arises from the great development of the tympanic arches, or from the distance between the parietal bones on each side of the head. There is often also a great depression of the nasal bones, which contributes to give a flat appearance to the face. The profile of the forehead is retiring or depressed, seldom found perpendicular. The profile of the jaw is prognathic or projecting, seldom found on a level with the forehead. The eyes frequently present the peculiarly called oblique. The skin is of a mixed character, never truly white, and very rarely of a jet-black; still it often presents what would be called a black or white colour. The eyes are generally of a dark colour. The hair, as a general rule, is straight, long, and black; in some instances it is curly—rarely woolly—and rarely still light-coloured.

The languages of the people belonging to this variety are either characterized by the absence of cases (apotic), or by having inflections expressed by the union of different words (agglutinate). They are very rarely amalgamate.

The distribution of this variety is very wide over the surface of the earth, and finds its greatest development on the continent of Asia; though wherever it is found it is not to be entire possessor of the earth. The Persians of northern and western Persia, the Kurds, the Beloebhi, the Afghans, the Tajiks of Bokhara, and the Siaposh must all be regarded as
belonging to the Japytidae. On the other hand, although we shall find the Japytidae the principal occupants of Europe, there seems to be little doubt that the Lapps and Fins of Scandinavia, the Hungarians of Hungary, the Turks of Turkey, the Magyars or Esualdines of Biscay and Navarre, and probably even the Albanians or mountaineers of ancient Illyria and Epirus, all belong to the Mongolidae.

From the analogy of language this variety is made by Dr. Latham to include the whole order of the inhabitants of the Poleonides Islands, as well as those of America. Although at first sight the physical differences between the Asiatic Mongolidae and the inhabitants of the islands of the South Seas and the continent of America might look as great as those between Mongolidae and Japytidae, yet it has been found that even physical characters fail to afford a line of demarcation. Thus, the late Dr. Morton, of America, thought that "the squared or rounded head, the flattened and vertically disposed nose, the small mouth, the large quadrangular orbits, and the low receding forehead," were characters that would distinguish the American from all other varieties. When however we examine the languages of the American continent we shall find that the Esquimaux present so strong a relation to that of the other races that we cannot deny their affinity to the American races; and it is amongst the Esquimaux that we find a departure from the physical type of a peculiar American form, and a strong relation with the Mongolidae. It is considerations such as this which have induced recent ethnologists to regard the American Indian as a form of the variety of mankind to which the followers of Genghis-Khan belong.

The influence of the races included under the variety of Mongolidae must be regarded as rather material than moral. They undoubtedly form by far the largest portion of the human race, and occupy a considerable space in the history of the world. They have, by necessity, established some of the largest empires that the world has seen. China is at this moment an example. Their empires have however crumbled to pieces, and left no deep impression on the world. Such is not the history of the Atlantidae and Japytidae, the first of which includes the Jews and the Mohammedans; and the last the Greeks, Romans, and modern European races.

The Mongolidae are divided by Dr. Latham into groups as follows:

A. Altica Mongolidae.—The term Altica is taken from the Altai Mountains in Central Asia, these being a convenient geognostic term for the different nations and tribes composing this division. It embraces two stocks, the Seriform, and the Turanian.

The Seriform stock has the physical conformation of the Mongol; and its languages are either wholly apotic or with only a few words distinctively Mongoloid in form. The area inhabited by these people is China, Tibet, and the Indo-Chinese or Trans-Gangetic Peninsula as far as Malaya; the Himalayan and parts of the Sub-Himalayan range of mountains.

In this stock the chief peoples are Chinese, Tibetans, Annamites, Siamese, Khasi, Bengalees, and Indians; and several unplaced tribes are added by Dr. Latham.

The Turanian stock has the physical conformation of the Mongol; the languages are not monosyllabic. They are found from Kautocheka to Norway, and from the Arctic Ocean to the frontiers of Tibet and Persia. The countries included are the northern parts of the Chinese empire, the greater part of Siberia, Mongolia, Tartary, Eastern Turkistan, Asia Minor, Turkey, Hungary, Ethiopia, and Lapland. They are distinguished as follows:

1. The Mongolian branch, including the Mongola proper, the Buriats, the Kamuks of Russia, and the Kinaf or Khinac of Persia.
2. The Tungusian branch including the Tchajpoh or the Lenas, the Lamuts on the Sea of Okhotak, and the Manchus or Chinese.
3. The Turk branch: this includes the Uighurs, the Turks of the Desert, Turks of Khoten, &c., the Kirghis, Uzbeks, Tadjiks, Turks of the Russian empire, and the isolated Yakuts of the Lena.
4. The Ugrian branch includes the Yapsas, the Permans, Tcherméis, Finlanders, Esthonians, Lakelanders, and Hungarians.

B. Dicranian Mongolidae.—The term Dicranian is taken from the ancient seaport Dicranas, and the tribes included in it have a modified Mongol organisation, the languages are (parasyllabic) few-syllabled and agglutinate. Of all the languages not belonging to the Seriform stock of the last section they approach nearest to the apotic state. They embrace the language of the Georgians 9, the Legiats 5, the Mistijit 4, the Iron; and 6, the Circassians.

Of this group, Dr. Latham observes, "To have used the word 'Caucasian' would have been correct, but inconvenient. It is already misspelled in another sense, that is, for the Mongolians. Yet for the race called Caucasian not only is said to consist of Jews, Greeks, Circassians, Scotchmen, ancient Romans, and other heterogenous elements. In this sense it has been used in more than one celebrated work of fiction. In such and in such only, it is otherwise than out of place."

C. Oceanic Mongolidae.—The epithet Oceanic is applied to this group, because, with the exception of the peninsulas of Malacca, the tribes belonging to it are the inhabitants of islands exclusively. With the exception of Mauritius, the Isle of Bourbon, Ceylon, the Seychelles, the Maldives, and the Laccadives in the Indian Ocean, and the Japanese empire, with the islands to the north thereof in the Chinese Sea, every inhabited spot of land in the Indian and Pacific Oceans is inhabited by tribes of one and the same race. In the Indian Ocean this division is not to be found spread over these islands, but apparently nowhere else. "In the peninsula of Malaca," says Dr. Latham, "and on no other part of the mainland of Asia, is an oceanic tribe to be detected. Although united by Dr. Latham exhibit two very distinct forms, one black, yellow, olive, brunette, or brown, with long, black, and straight hair. Another class is black rather than yellow; the hair is sometimes long and straight, but in other cases short and curly. These are found in many different parts of the world, and the intellectual difference between these two classes is less than their physical. The black division inhabits New Guinea, Australia, Tasmania, New Ireland, and the islands between it and New Caledonia. The brown division occupies all the rest of the oceanic area, Sumatra, Borneo, Java, the Moluccas, the Philippines, the South Sea Islands, the Carolinas, &c. The names given to these divisions are as follows:

1. For the lighter-complexioned straight-haired type—Melanesian.
2. For the type that partakes of the character of the African negro inhabiting New Guinea, Australia, and what may be called the continuous localities for the umixed black—Negrito.
3. The tribes with any or all of the Negrito characters, dwelling side by side with Malays in Malay localities, or in localities disconnected with the true Negrito area—the blacks of the Malayan area.

D. Hyperborean Mongolidae.—The physical conformation of this section is that of undernourished Mongolians. They are called, by the Chinese, "a people not very different from the Mongolians," and are not only is this race to be found spread over these islands, but apparently nowhere else. The black division inhabits New Guinea, Australia, Tasmania, New Ireland, and the islands between it and New Caledonia. The brown division occupies all the rest of the oceanic area, Sumatra, Borneo, Java, the Moluccas, the Philippines, the South Sea Islands, the Carolinas, &c. The names given to these divisions are as follows:

E. Peninsular Mongolidae.—This section comprises races very widely distributed. Some of these lie within the arctic circle, others as far south as 26° N. lat. Their physical conformation is Mongol. Their languages are agglutinate, and the chief tribe occupies the north-eastern coast of Asia. The people emigrated in it are the Koreans, the Japanese, the Aino, the Koriak, and the Kamchadales.

F. American Mongolidae.—This section embraces the oceanic people of the whole continent of America. By most writers on ethnology, the races of America are regarded as a distinct family. Their connection with Mongolidae seems however to be established by the Eskimo, who are physically Mongol and Asiatic, but philologically American. Of the Eskimo Dr. Latham remarks: "Unimportant as are the Eskimo in a political and historical view, their peculiar geographical position gives them an importance in all questions of ethnology; since one of the highest problems turns upon the affinities of this family."
G. Indian Mongolida.—The races belonging to this section are found in Hindustan, Cashmire, Ceylon, the Maldives and Laccadives, and part of Beloochistan. They are found mixed or contiguous to the Japetidæ of Beloochistan and Cabul, and various Serifian tribes. They present two extreme forms of physical characters, one being dark or even black, the other of a brunette colour, with a skin of great delicacy and clearness. The social condition of castes prevails amongst them. The principal religions are Brahminism and Buddhism, with a variety of intermediate creeds. Their distinct language is in the Sanscrit, and their alphabets are derived from that language. They embrace the following divisions:—1, the Tamuli; 2, the Palinda; 3, the Brahî; 4, the Indo-Gangetic; 5, the Parbuttî; 6, the Cashmirean; 7, the Gînsâli; and 8, the Maldivian.

II. The ATLÂNTICA.—In their physical character the face is not so broad and flat as in the Mongolida. The jaws are thin, the profile are prognath, whilst the nose is generally flat, the forehead is retreating, the cranium dolicocephalic, that is, there is less space between the parietal bones of the skull, whilst its length remains the same, than there is in the last variety; the eyes only rarely open obliquely, the skin is mostly jet-black, presenting however lighter shades, and very rarely approaching a pure white; the hair is crisp, woolly, very rarely straight, and still more rarely light-coloured. The languages adopted by the Atlantean peoples are the same in the eight principal classes. They are seldom or never found with a truly amalga-mate infection.

The great district of the development of the nates which are brought together under the above definition, is Africa. Perhaps the greater part of all the inhabitants of the greater diversity of inhabitants than Africa, or races of men who at first sight appear so evidently distinct. All the ethnologists have placed the Hottentot, the Negro, and the Bushman in a variety Atlantea. The analogy of language has led to this conclusion; and the transition from the Bushman to the Hottentot is so gradual that no investigation of their physical structure with which we are at present acquainted, would be sufficient to break down the affinity discovered in their languages. No part of Africa seems to be inhabited by any races but those of the Atlantea. The Syro-Arabian or Semitic nations, however, which are now classed amongst the Atlantea, are found occupying a considerable area in the southwestern part of Asia. The people of these races are far removed from the Negro and the Hottentot, though the symmetry of form, and considerable cerebral development.

However small may have been the influence of the lower types of this race on the world, there can be no doubt of the vast improvement produced by the negroes over the early civilization indicated by the Assyrian and Babylonian empires, and fix attention on the religious history of the Jews. Here, amidst the surrounding Paganism, we find the worship of the one true God maintained by this small race amongst the Semitic nations; and through them the religion of Christ, which is destined to react on all the other races of mankind. It is also among these races that that compound of Judaism and Christianity, Mohammedanism, has sprung up, and whatever inferior it may be to the Christian religion, there can be little doubt of the beneficial influence it has exerted on the races who have embraced it.

The following is Dr. Latham's division of this group:—

A. Negro Atlantea.—The negroes have a black, unctuous, and soft skin; the hair woolly; lips thick; maxillary profile prognath, frontal profile retreating; nasal depressed. They inhabit the mouths of the great rivers, chiefly the Senegal, Gambia, Niger, and Upper Nile. They are nearly limited to the tropic of Cancer. They are divided into Western Negroes, Central Negroes, and Eastern Negroes.

B. Kafr Atlantea.—The language of the Kafr supplies a broad distinction between these races and those of the Atlantea. Their physical conformation is modified negro. They occupy a district in Africa (east and west) from the north of the equator to the south of the Tropic of Capricorn. The chief divisions are, 1, Western, 2, Southern, 3, Easterns.
The influence of this variety of mankind on the history of the world, has been much greater than that of the other two. If we add India, the Semitic races for the truth of Christianity, its adoption and propagation in a pure form has been mainly due to European nations. It became early identified with the civilization of Greece and Rome; and passing from the nations where it obtained its early triumphs, it has finally reached its last empire, the religion of the great Anglo-Saxon race, which on both sides of the Atlantic is increasing with extraordinary rapidity.

Dr. Latham divides the *Japetidae* into two divisions—Occidental and Indo-Germanic.

A. Occidental *Japetidae* include the races called Celts or Kelts. The Keltic languages were separated from the common mother-tongue subsequent to the evolution of the persons of verbs, but anterior to the evolution of the cases of nouns. These languages are evidently agglutinative. The present area of this race is Brittany, Wales, the Highlands of Scotland, the Isle of Man, and Ireland. The original area occupied by the Kelts, which have been constantly removed, is the Scottish Lowlands, England, Gaul north of the Loire, and part of Switzerland. It is probable also that they occupied parts of Baden, Bavaria, and northern Italy. The Tarasici of the Tyrol, the Scordisci of Illyria, the Gitans of Asia Minor, the Celt-Iberians of Spain, and the Cimbri who lived in northern Germany, are generally termed Kelts. They have two types of complexity in the British Islands: the Silurian type having eyes and hair black, complexion dark with a reddish tinge, and chiefly found in South Wales; the Hibernian type having grey eyes, yellowish, red, or sandy hair, and light complexion; they are found in Ireland.

Dr. Latham gives the following as their chief divisions:

1. Kelts of Gaul, falling into—
   a. The proper Celts; &
   b. The Belgae, both extinct or incorporate.

2. British Celts, falling into—
   a. The Cambrians; &
   b. The Picts, which are extinct or incorporate.

4. The Celtiberians of northern Italy.

5. The Ligurians, extending from the Etruscan to the Iberian frontier.

Their line of population seems to have been from Celtic and Dunsirk to England, from England to Scotland, and from Scotland to Ireland.

B. Indo-Germanic *Japetidae*. The languages of this group were separated from the common mother-tongue subsequent to the evolution of the cases of nouns. They are less evidently agglutinative than the Keltic. This and the previous group are sometimes called Indo-European, and thus embracing all the *Japetidae*. The Indo-Germanic *Japetidae* further divide into two classes:

1. European Indo-Germans.—These are divided into:

1. The Goths—

a. The Tentons, which are again divided into:
   a. Magogoths.
   b. High Germans, including Hessians, Thuringians, Franks.

2. Low Germans, including:
   a. Batavians, embracing—
      * Saxons of Hanover, and Anglo-Saxons of England.*
      * Saxons of Osmund and Westphalia.*
      * Nordsalzburgians. Extinct.*

3. Frisians.

b. Scandinavians, embracing—
   a. Icelanders.
   b. Norwegians.
   c. Scandinavians.
   d. Swedes.
   e. Danes.

2. Sarmatians. This comprises the Lithuanian and Slavonic divisions, and these are its primary sections.

Of the Lithuanians Dr. Latham says—

1. Of all the *Japetidae* they preserved their original languages.

2. Of all the *Japetidae* they had the least influence on mankind.
MAN

3. Of all the Japetides they speak a language nearest in structure to the Sanscrit. The Slavonic division includes—
  a. Russians.
  b. Servians.
  c. Lithuanians.
  d. Tekebs.
  e. Poles.
  f. Serbs.
  g. Polavian Slavonians.

3. Mediterranean Indo-Germans. These include the Greeks and Romans of antiquity, and their modern descendents.

II. Iranian Indo-Germans. — Dr. Latham says "the whole of this class is hypothetical." It includes the Persians, who embrace the Kurds, the Balouchi, the Afghans, the Siaposh, and other contorted races in Asia. The unplaced stocks are the Armenians and Iberians.

MAN, FOSSIL. [ANTHROPOLOGICAL, 2. 2]

MANBY, CAPTAIN GEORGE WILLIAM, the author of several inventions applied to the saving of life in shipwreck, was born at Hilgay in Norfolk, on November 30th, 1765, and died at his residence Pedestal House, Somers Town, near Great Yarmouth, on November 18th, 1854, thus having nearly completed his eighty-ninth year. He adopted the military profession, but appears to have retired from any active duty after he had attained the rank of captain in 1803, when however he was appointed barracks-master at Great Yarmouth. Here in February 1807 occurred the loss of the Sibbe gun-brig, when he saw sixty-seven persons drowned within a few yards of the beach; and, in the same gale, so many vessels were driven on shore that the coast was covered with dead and miserably wounded men on makeshift stretchers of raw timber, and seven dead bodies were cast upon a line of coast of about thirty miles in extent. Such calamities induced him to devise means of assistance by throwing a line over the vessel. This was at first proposed to be done by a balloon; but a successful experiment with a small mortar, when he threw a line over a church, led him to prefer the use of gunpowder. The great difficulty to be overcome was as to the connection of the shot with the rope. Chains broke on the discharge. At length, in 1811, stout strips of raw timber closely platted, were found to answer, and on the 12th of February 1808, when the crew of the brig Elizabeth were in imminent danger, about one hundred and fifty yards from the beach, Captain Manby threw his shot at them from himself to the rigging with the shot breaking over them, and in what would have been a hopeless position, Captain Manby threw a line over the vessel, a boat was hauled off by it, and the crew of seven men were brought to land. In the same severe winter Captain Manby rescued the crews of several vessels by similar means. In 1810 his services were brought before the House of Commons. A committee was then appointed on the subject of the saving of life in shipwreck. The merits of previous inventions for the same object were brought before that committee, especially by the friends of Lieutenant Bell of the Royal Artillery, who in 1798 had communicated to the Society of Arts a plan for throwing a rope from a mortar to a vessel itself, and to whom 60 guineas had been awarded after some experiments at Woolwich. That plan however would have been obviously very difficult of application in the case of a vessel in a raging sea. Captain Manby having been reported of with high approval by the Committee, received a pecuniary recompense from the Exchequer, and was employed to report upon the dangers yet to expect from shipwreck from Yarmouth to the Frith of Forth. He advised that mortars, constructed on his principle, should be stationed at various points; in 1814 the House of Commons addressed the Prince Regent on the subject of erecting such stations, and provided with the requisite apparatus. The attention which was thus given to the subject of the preservation of life in cases of shipwreck, was further expressed through associations which were formed throughout the country chiefly by Captain Manby's exertions. He also contrived means of obtaining a sight of a vessel on a dark night, by the use of a description of firework throwing stars at a certain height; and he suggested the use of shells, filled with a burning composition, to allow the crew to discover the flight of the ship, and to fire rockets by attaching a manufacture of ropes to prevent milder and rotting vegetable mucilage, and using a solution with sugar of lead and alum in equal parts; and he suggested various improvements in life-boats. Late in life he visited the Northern seas, chiefly for the purpose of testing a new form of harpoon which he had invented. For his various inventions, which were the means of saving upwards of a thousand lives, he received at various times 7000£ from the British nation, and the thanks of several nations of Europe.

MANDAMUS. The Writ of Mandamus, mentioned P. C. v. xiv., p. 347, and which can only be obtained in the Court of Queen's Bench, is now usually termed the Prerogative Writ of Mandamus, in order to distinguish it from the writs mandamus and absolute in certain cases in all the other Superior Courts of Law.

The proceeding by Prerogative Writ of Mandamus may be resorted to, as it has been already pointed out, in cases where a public inconvenience or a private wrong is occasioned by the omission of a public duty, and no sufficient remedy is afforded by an action for damages. This remedy was originally confined in its operation to a limited class of cases affecting the administration of public affairs; such as the execution of public statutes, or compelling inferior courts to proceed in matters within their jurisdiction, or public officers to perform duties imposed upon them, as to make a rate and the like. But in more recent times it has been extended to cases in which the rights of private individuals only are concerned. In every case found of Prerogative Writ of Mandamus, the petitioners are passed for making railways, docks, bridges, improving towns, &c., &c., and, in almost all such Acts, there are provisions directing the company obtaining the Act to do certain works for the benefit of individuals; such as substituting new buildings for others necessarily removed, making new communications in lieu of old ones, and other works of a similar nature. In the event of noncompliance with these enactments, the remedy is by mandamus. This mode of proceeding has received much attention from lawyers; in the legislative act, the procedure therein has been very materially altered and amended by the Common Law Procedure Act, 1854, the proceedings being now assimilated as much as possible to those in an ordinary action.

The remedy hitherto afforded by this prerogative writ, in cases where the public were interested, has, by the same statute, been extended to cases in which private rights only are concerned. The plaintiff may claim in his writ the performance of the act which he is entitled to have demanded, and the claim must be repeated in the declaration, which must set forth the sufficient grounds for the claim, and show that the plaintiff is personally interested therein; that he sustains or may sustain a pecuniary loss by the non-performance of the duty demanded, and that performance of which is demanded; and that performance thereof has been demanded by him, and refused or neglected by the defendant.

Where judgment is given that a mandamus do issue, the court, if it shall see fit, besides issuing execution in the ordinary way for the costs and damages, may also issue a peremptory writ of mandamus, commanding the defendant forthwith to perform the duty to be enforced, which the defendant must obey; for no return, except that of compliance, will be allowed, although at the time to return the writ may, upon sufficient grounds, be obtained.

If the defendant fails either to obey or to return the writ, two courses are open to the plaintiff. He may cause the defendant to be attached; or instead of proceeding by attachment, the court may, upon his application, direct the act required to be performed by the writ to be done by the plaintiff himself, or some other person appointed by the court, at the expense of the defendant; and upon the act being done, the amount of such expenses incurred be recovered by the court, who may order payment of the amount of such expenses and of the costs, and enforce payment thereof by execution.

MANGO-TREE. [MOONGATELA]

MANILOT. [JANIBHA, S. 2]

MANIN, DANIELE, a distinguished Italian politician and patriot, was born at Venice in 1804, the son of Pietro Manin, a respectable advocate. His grandfather, Lodovico Manin, bore the same name as the last doge of Venice, whose weak behaviour at the time of the extinction of the
ancient republic by Bonaparte (1797) had attached a certain discredit to the name. Young Manin, who from the first showed great abilities, was bred up to his father's profession of the law, and graduated as Doctor of Laws at the University of Padua at a very early age. He married in 1826, and shortly afterwards commenced practice at law and took upon himself the guidance of the Manin family. However, he led a quiet domestic life, employing his leisure in historical and legal studies, and occasionally in writings of a kindred character. From the first however he shared fervently in the thoughts and the conversations of his own Austrian统治, and the general aspiration after restored liberty and independence for Venice. Though not affiliated to any of the revolutionary societies then existing in Italy, he often discussed with several intimate friends, especially Alexandre Zamboni, Count Cattaneo, Giovanni Maffei, and Francesco delle Antoni—the wrongs of his native country, and the possibility of remedying them by insurrection or other means. Once or twice—as during the time of the excitement caused by the affair of the brothers Bandiera in 1844—these secret communings were on the point of bursting out into open action; but, on the whole, it was felt by the friends that no movement was practicable, and Manin continued in the ordinary exercise of his profession, varying it by occasional contributions on economical topics to journals. As a speaker, he was distinguished for a logical, direct, positive, and conclusive manner, different from the ordinary eloquence of his countrymen. As on several important points, he and his friends, in the Congress of Vienna, came in collision with the Austrian government; and in the early part of 1848 he was imprisoned. But this year was to witness a change in his fortunes, and in those of Italy. On the 18th of March the spirit of insurrection with which the whole peninsula was charged, broke forth in Milan; the news of the expulsion of the Austrians from Milan acted immediately on Venice, and on the 33rd of March the Austrian commander of the city, Count Zichy, was obliged to surrender, and the republic was declared. It was at this time that Manin stepped forth as a man born to lead. The progress of events was for a time complex—the fate of the Venetians being involved in that of the other Italians. What we preferred," Manin afterwards said, "was to be in the peninsula, then, divided, divided, divided; in the other Italian states; but what we would have accepted was, to become a portion of one great kingdom comprising all Italy.

The war of Charles-Albert, the king of Piedmont, against the Austrians in the name of Italy, as a whole seemed for a while to give likelihood to the latter expectation. The Venetians, willing to show their trust in Charles-Albert agreed to the fusion of their little republic with Lombardy and Piedmont, and form a new kingdom of Northern Italy. But the battle of Custozza having ended that dream, and restored Lombardy to the Austrian dominion, the Venetians again fell back upon their own resources and protested for a separate defence. The citadel of St. Mark was again hoisted; a triumvirate was appointed to carry on the executive government, Manin being the chief of the three; and the military command was intrusted to the Neapolitan general Pergo, who had thrown himself into Venice two months before, rather than obey the order that he should return to Naples. Though the Austrians kept up a blockade against Venice, it was not till March 1849, when the second attempt of Charles-Albert was broken and the French were defeated when entering Trieste, that the Austrians were thus free to reconquer all that still remained to be reconquered of their lost territories in Italy, that the Venetians endured the full agony of the struggle. By that time the patriotic movement had been completely crushed in every part of Italy besides, with the exception of Rome. The two republics of Rome and Venice were the sole remains of the insurrectional work of the previous year; and against one of these the French were making the most formidable attack in the history of geology. But the other was not so much to the Austrians alone. Both republics behaved bravely. What Maximiz was to Rome, Manin was to Venice. From March 1849 he was inviolate with all the powers of the dictatorship. The defeat of Venice, confirmed by the treaty of Vienna, was gallant and obstinate in recent history. It was on the 3rd of July that the French entered Rome; but Venice did not surrender till the 24th of August, after it had suffered a dreadful bombardment. With the fall of Venice the re-subjugation of Italy was complete. The terms of the surrender were such that Manin was able to go safely into exile. He afterwards resided chiefly in Paris, supporting himself honourably. He died September 28, 1857.

MANTELL, GIDEON ALGERNON, a palaeontologist and geologist of extensive and varied acquirements, was born at Lewes, in Sussex, about 1790. For several years he practised as a medical man at Lewes, in a district which he regarded as one of the richest specimens of geological structure in Great Britain. He was a memorable instance of a man of genius, constantly and diligently occupied in discharging the duties of a laborious profession—in which he acquired great provincial reputation, especially in the methodical construction of his valuable geological works, and for the tenderness of his demeanour to his patients—nevertheless reaching great eminence as a man of science, and finding time to pursue his favourite studies with distinguished success. During his residence at Lewes he collected a vast number of interesting fossils, and formed a private museum, such as has rarely, if ever, been equalled. Here also he published his principal separate works, 'The Fossils of the South Downs,' and 'The Illustrations of the Geology of Sussex.' The former appeared in 1822, simultaneously with that of Cuvier and Bridges concerning the 'Mammalia.' The Geology of the Environs of Paris; and many of the organic remains of the chalk were described in both works simultaneously, though independently. Whilst at Lewes he also called attention to the remarks of Cuvier on the remains of fishes found in the chalk, and it was there he commenced the series of observations which placed him in a prominent position among British geologists. His attention was early directed to the phenomena exhibited by the ammonites, and he advanced theories, in many instances, that are now underlie the cretaceous system in the Weald district, happily designated by his friend Mr. P. J. Martin as the 'Wealden Formation.' His location being exceedingly favourable for researches in this considerable branch of the science, he became the original demonstrator of the fresh-water origin of the mass of Wealden beds, thus making a great step in British geology; and it is remarkable and instructive that this resulted from the direct application of the knowledge of existing causes and phenomena to the investigation of the past. Mantell's observation of the conditions under which existing fresh-water shells were imbedded in the alluvium of the valley of the Sussex Ouse, and even alternated with marine exuviae, suggested the probability of the occurrence of similar, but immensely more ancient, phenomena in the clays and sands of the Weald; and careful research fully confirmed his conjecture. His chief and very memorable palaeontological discoveries are connected with the Wealden. But the particular and locality and specific geological ology have been pursued in England for many years past, most of the larger reptiles of the period being discovered in the Wealden rocks. The geological view of the subject is from the impartial pen of Mr. William Hopkins, F.R.S., and forms a part of an obituary notice contained in his 'Anniversary Address' from the chair of the Geological Society, on the 18th of February 1853, on which the present article is founded.

Out of the Wealden, Mr. Hopkins states, Dr. Mantell "procured the most interesting of the relics of prodigious extinct reptiles, which owe to him their scientific appellation. Among these, I may name the wallower, the chief attractions of the great collection originally amassed by him, and now displayed in the galleries of the British Museum. Whether we regard his discovery and demonstration of the Iguanodon and its colossal allies in a geological point of view, as characterising distinct epochs of earth's history, or, with respect to their zoological value, as filling up great gaps in the series of Vertebrata, and elucidating the organisation of a lost order of reptiles, at once highest in its class, and most harmonious of form, in the history of the Mammalian type. Their characters were so peculiar, that the value and distinctness of their order there can be no question. Their ology has been elaborated with skill and care, and has worthily occupied the attention of the
most eminent anatomists. They give a feature to the herpe-
tology of the middle portion of the secondary epoch. Now,
of the five marked constituting this group, as at present
known, we owe the discovery of the variety and form
of—vix., Iguanodon, Hylaeosaurus, Pelorosaurus, and Reg-
osauros—to Dr. Mantell. Worthily then were the Wol-
kaston Medal and Fund adjudged to our lamented colleague in
the 'Iguanodon' having been followed by the 'County
Hill' and 'Queen's Head,' by Sir Charles Lyell, Edward
Wallace, Brayley, F.S.A. In the 'Bibliographia Zoologica et Geologica'
of Agassiz and Strickland, no fewer than sixty-seven works
and memoirs of various degrees of importance and length, are
enumerated as having proceeded from Dr. Mantell's pen; to
these must be added many works of an antiquarian nature, and several
professional disquisitions.

MARMOLITE. [MINERALOGY, S. I.]
MARQUESE LOUISE VIENIE DE, MARECHAL DUC DE RAGUSE, the son
of the Chevalier de Marmont, an old friend of distinction,
who was born at Châtillon-sur-Seine, on the 20th of July
1774. He entered the army as sub-lieutenant of infantry in
1789; but his father was killed in the battle of Jemmapes,
the 1st of November, 1792, to the Artillery School of Châlons.
Towards the end of that year he served in the campaign of
the Alps, under General Montesquiou. He was present at
the siege of Toulon, December 1793, and having been
appointed chief-d'escadron, he was sent to Italy, in 1796,
by the order brought by the treaty of Vendemarie (October 6,
1795), Marmont, having been appointed chief d'escadron,
was sent to Italy in March 1796, as principal aide-de-camp to
General Bonaparte. In this famous campaign he was present
almost everywhere; at Lodi, at Castiglione, and at the battle
of Saint-Maur, was chosen as his aide-de-camp, and made a captain
in 1794. In this capacity he accompanied his general to the
army of Italy, during the campaign of that year. After the great
sur-
render of 1796, at the battle of Vendemarie, General Marmont
was one of the seven officers selected to bear his company in his perilous
enterprise.

During the crossing of the Pyrenees and the spring of
1798, Marmont's plans for the conveyance of the guns
having been adopted, he superintended the entire transport,
and by his persevering efforts the passage of this important
arm was effected. He fought with much distinction at
the battle of Marengo, June 14, 1800, and was immediately after
raised to a division. After the peace gained by this victory,
he was made inspector-general of artillery; he then applied
himself zealously to various reforms in the service, especially for
the selection of the personnel for the artillery train. All
these improvements were sanctioned by the First Consul,
though the young military reformer was only in his twenty-
seventh year.

In the campaign of 1805, General Marmont was present
at the capture of Ulm, October 20, 1805; and he was next
successively employed in the reduction of the province of
Styria. Henceforth he commanded armies. In 1806 he
was sent to command the army in Dalmatia, where he acted
generally as recruiting agent. On May 27, 1808, with an army of 6000 men,
be defeated an allied corps of
9000 Montenegrins, Greeks, and other troops, sustained by
the second corps of 7000 Russians. During his occupation
of the duchy, Marmont carried out a beneficial system of public
works, including a grand line of railway, 210 miles in
length, for which useful improvement he received his title of
Duc de Raguse in 1808.
opened in 1809, Napoleon called this general to support his
main army. Marmont took the field with a corps of 3900
infantry, only 300 cavalry, and 12 pieces of cannon. With
this force he defeated the Austrian army, which numbered
several severely contested engagements; and then encounter-
ing General Gnyiay, at the head of 35,000 troops, posted on
the Drave, compelled that general to retreat into Hungary.
After these successes he joined Napoleon the day before the
great battle of Klosterman, on the 1st of July 1810, and
rejoined him at Vienna on the 10th. He placed himself in
front of the offensive action, and received his marshal's baton for his conduct in
that arduous engagement. This decisive victory being fol-
lowed by the treaty of Vienna, the Austrian government
made him the viceroy of Bohemia, the provinces of Ragu-
s, and Croatia, with other adjacent lands, which Napo-
leon formed into a single state, under the title of the Illyrian
Provinces, and placed them under the direction of Marshal
Marmont as governor-general. In this high office he con-
tinued nearly sixteen months, giving proofs of superior
capacity as an administrator, whilst he was honourably dis-
tinguished from other marshals by his integrity and disinter-
estedness. Towards the close of 1810 he stood so high in
the esteem of his master, that he was sent into the peninsula
to supersede Marshal Massena in the command of the army
of Portugal. Though independent in his command, he hast-
tened to unite his army to that of Soult, placed himself
under the orders of that eminent leader, and assisted him in
relieving the garrison of Salamanca on the 22nd of July.
On the 22nd of July 1812, he displayed however many proofs of skill as
a general before he retreated, nor did he leave the field until
he and the two generals who succeeded him had been dis-
able. In the autumn of 1813, after the great battles of
tillers, Marshal, though scarcely recovered, took the command of
the second corps, and was present at Bautzten, May 20, 1813; at
Dresden, August 26, and at Leipzig on the 16th, 17th and
18th of October. In this last battle he defended the village of
Schoenfeld, which was taken and retaken seven times.
Eight of his generals were either killed or wounded in
the action; four horses sank under him, and he was twice
wounded.
As commander in chief in 1813, he appeared again in almost every battle fought on
the French soil, in 1814, for the defence of his country. He
terminated this campaign, perhaps the most brilliant in his
career, by the battle before the walls of Paris, on the 30th of
March 1814. The enemy, consisting of Russians, Prussians,
and Austrians, were more than four to one, yet Marmont
maintained his post for several hours, not surrendering even
when the heights of Montmartre had been taken, and the
first Russian guns had begun to sweep the Boulevards within
the walls. Marmont, till the 11th, received the congradula-
tions of all his foes, after receiving a letter from Joseph Bonaparte authorising them to consider
that Marmont and Mortier called a council of general officers
at an inn within the suburb of La Villette, when they agreed
to the evacuation of Paris.
That night the French entered the French capital on the
1st of March, and Marshal Marmont, on the 4th of April,
after a short correspondence with Prince Schwarzenberg,
stipulating for the retirement of the French troops into
Napoleon's baggage, baggage, and artillery, entered the
allied lines, and then marched to Versailles. It was this
step, taken without the sanction of Napoleon, which after-
wards drew upon him such odium.
The Duc de Ragueneau was now wedded to the cause of
the restored dynasty. He accompanied Louis XVIII. to Ghent
in 1815, returned to Paris with that sovereign after the battle
of Waterloo, and was employed repeatedly both by that
monarch and Charles X. in offices of great trust. At
the outbreak of revolution in 1830, he was charged with
the invidious duty of quelling the revolt, and having failed
became a second time the mark of almost universal obloquy.
To satisfy the popular indignation, he was struck off the
list of the French army, and exiled from France. He spent
his years of banishment in writing different countries, and in
writing works of considerable merit on the military systems of
Russia, Austria, and other states. Nearly twenty-two
years after his disgrace, he died at Venice, on the 2nd of
March, 1837, in his eighty-fourth year. The publication of
the 'Memoires du Duc de Ragueneau,' in 9 vols. 8vo, was
completed in 1857.
MARRAST, ARMAND, who succeeded Carrel as chief
editor of 'Le National,' was born in 1802, in the south of
France. He was educated for the church by the Jesuits of
Le Davy, he went to Paris in 1827, and immediately com-
missioned his career of politics by writing pamphlets against
the government. The pungency and playful humour of
these light productions drew notice upon the author, and he
at once made for himself a distinct position among the
young of his time. His chief work, 'Les Hommes,
avid vivant,' was written in the French capital, a vivid contest being waged between
the practical school of philosophy, conducted by Lar-
miguere, and the eclectic school, presided over by Cousin.
Marrast entered the ranks of the former about six months
after the publication of the work, and speedily passed the
price by the light curriculity of his pleasant brochures towards Cousinism.
In 1830 Marrast established the newspaper 'La Tribune.'
It became the organ of the ultra-liberal party, and as such was supported by foreign as well as French
journals. It contained very bitter articles against the govern-
ment of Louis Philippe, and the fines to which it was
condemned, together with the law-expenses attending its
defence, put an end to its publication after a few years.
Armand Marrast, on one occasion, was called to
the Chamber of Deputies on account of two articles in 'La Tribune.'
On another occasion he was arrested and sent to
prison as one of the conspirators concerned in the 'complot
d'Avril.' He was soon released, and when he published his
celebrated pamphlet, 'Vingt Jours de Secret,' which pro-
duced a great sensation, and much increased his popularity.
Proceedings were taken against him by the ministry. He
sought refuge in England, remained several months in
London, where he nutured his ability to 'Le National,' and married an English lady during
his sojourn in this country. These letters were the origin of
that long connection with Armand Carrel and 'Le National,'
which he maintained to the end of his life, over his countrymen. He became sub-editor of 'Le National'
in 1834; and on the death of Carrel, July 24th, 1838, he
succeeded him as chief editor. From this time until the
revolution of February 1848, a period of nearly twelve years,
Marrast conducted that journal, which he had raised to its
high position it had acquired under Thierry, its first editor,
and then under Carrel.
During 1847, a series of exciting incidents rapidly followed
one another, throwing on Marmont and Mortier a
considerable accession of power. At one time, it was a course of ministerial prosecutions; at
another, rumours of bribery and corruption among men high in office; next, these rumours were succeeded by
flagrant exposures or confessions; and lastly, came the scandal of
assassination in the mansion of a great noble. The repub-
lican journals made the most of these incidents, and 'Le National' took the lead in
denouncing the government and the court. The revolution of February, and the abolition of
Louis Philippe followed. Pending the crisis of events, Marmont came to the capital, became
a member of the new ministry; and deputations visited Marrast, and received their instructions from him. His name now was on every tongue; and when Lamartine was placed by the rapid
proceedings of his party at the head of the government, Marrast became secretary, afterwards maire de Paris, and
finally president of the National Assembly. This last office was limited by a new regulation to one month; but the
ubiquity of the new president, and his extraordinary influ-
ence over the 900 members in consequence of his tact
in calling them to order by humorous appeals, caused him to be
re-elected several times. To him likewise was committed
the task of drawing up the new constitution. But the
republican party soon found that Marrast was not advanced
enough for them; they began to stigmatise him as a moderate,
and his popularity fast declined. On the 15th of May 1848
the insurgents, headed by Barbeis and Blanqui, forced their
way into the Hotel-de-Ville, their first cry being 'Marrast! We
must make an end of that self-same-handed republic-
ian!' But he had withdrawn for concealment to a private
chamber which was not searched. After the insurrection
of June, and the consequent dissolution of the Lamartine
cabinet, Marrast retired into private life. We believe
that he still contributed to 'Le National' without any longer
being its editor, until the paper was suppressed by the
government of Louis Napoleon. He died on the 10th of
March 1863.
MARRAST. Provision is made for the licensing of
district chapels and churches for the celebration of marriage,
by the stat. 7 & 8 Vict. c. 56. The notice given to the Superi-
ior Registrar must now be accompanied by a solemn
charge, that he shall not permit his officiating brethren to
be admitted into the church or chapel, as the certificate of
marriage may be obtained. This is provided for by the statutes 19 & 20 Vict. c. 119, which
also enables parties who have entered into the con-

M.R.
tract of marriage merely before the Superintendant Registrar, to have the ceremonies of the church or of their own persuasion added at any time afterwards. The object of this enactment is to permit marriage with any scruples which, after the merely civil form of the contract has been resorted to, may arise or be suggested to them. (Blackstone's 'Commentaries,' Mr. Kerr's ed., vol. 1, p. 464.)

MARRYAT, FREDERICK, was born in London on the 10th of April, 1792. He was an early and eager sporting loyalist. After being educated at various schools in and near London, young Marryat entered the naval service in September, 1806, as a midshipman on board the Impériéuse, 44 guns, commanded by the celebrated Lord Cochrane. Under this daring commander he was engaged in upwards of fifty actions, of more or less importance, off the French and Mediterranean coasts during the next three years. In one he was left for dead on the deck of a ship which he had boarded, and only recovered when a fellow midshipman, who had a grudge against him, touched his supposed dead body with his foot, and began to moralise in rather uncomplimentary terms on his premature exit from life. The reputation for gallantry and ability which he acquired under Lord Cochrane speedily recommendation with his higher commanders during three additional years of service as a midshipman. On four or five occasions he saved men from drowning by jumping overboard, at the risk of his own life. On one such occasion he saved the life of a son of William Cochrane, afterwards created a baronet. During his first two years he served as midshipman on board the Espigile sloop, whence he removed to the Newcast, sent under Lord George Stuart, to cruise off the American coast. He attained a commander's rank in 1815. In 1820 he commanded the Amazone, a man-of-war, which was changed into the Rosario, in which he brought home duplicate despatches announcing the death of Napoleon. After being employed for some time in the preventive service, he was appointed in March 1823 to the Lorme, 18 guns, and proceeded to the East Indies. He was senior naval officer in the attack on Rangoon, and in December 1824 he accompanied Sir Robert Sale in the expedition up the Bassein River. His good services in the East Indies procured him the thanks of the East India Company and general promotion. In June 1825 he received the decoration of C.B., and at the same time the Royal Humane Society awarded him its medal for having saved so many lives from drowning. From November 1825 to November 1830 he commanded the Arrisc, in which he made another voyage to the East Indies. There, about the year 1828, when he was approaching his fortieth year, that he began his career as a novelist by the publication of his 'Frank Mildmay.' This was followed at brief intervals during the next sixteen years by his other well-known writings, most of them novels of sea-life—'Peter Simple,' 'James Faithful,' 'Japhet in Search of a Father,' 'The King's Own,' 'Mr. Midshipman Easy,' 'Newton Forster,' 'The Pacha of Many Tales,' 'Rattlin the Reeler,' 'Snarly-yow, or the Dog-Fiend,' 'The Fishermen of the New Forest,' 'His Banner in Battle,' 'The Pirate and Three Cutters,' 'The Phantom Ship,' 'Poor Jack,' 'The Poacher,' 'Masterman Ready,' 'Pericival Keene,' 'The Narrative of Monsieur Violet in California, &c., 'The Settlers in Canada,' 'The Mission, or Scenes in Africa,' 'The Prisoner's Man,' and 'Valérie.' The merits of these works as amusing works of adventure and description are universally known. Besides these, he published in 1837 a work of a different class, 'A Code of Signals for the use of vessels employed in the coasting trade of the United States and the British government, and is now in general use by our own and all foreign navies, and which procured him the cross of the Legion of Honour from Louis Philippe. He also published in 1839 in two series of three volumes each, 'A Diary in America,' which he dedicated to Sir Stephen Sharp, once charged with affairs of State in Russia, he had six children. Of two of his sons who had entered the navy, one perished, before his father's death, in the Avenger steamer; one of his daughters has since appeared and another is a novelist. Captain Marryat was a Fellow of the Royal Society.

MARS, ANNE-FRANCOISE-HYPOLITE BOUTET, known as MADEMOISELLE MARS, was born in Paris on the 23rd of September, 1778; her father being the actor Monvel of the Théâtre de la Monnaie; her mother a very pretty actress named Mars-Boutet. She appeared before she was ten years old in juvenile parts, and in 1773 she already filled at the Théâtre Feydeau, what on the French stage are called 'les rôles d'ingénue.' She met with a general patronage at Mademoiselle Contat, then the leading actress in comedy, and received from her the best training for the cast of characters which her early talents pointed out as her own. After she had made herself familiar with these parts of the young girl, she was induced, still directed by Mademoiselle Contat, to attempt 'les jeunes amoureuses;' in which character she succeeded to the first place, after the retirement of Mademoiselles Méfray and Lange in 1778. She was then twenty years old. She acquired her fame by her talent, her fine taste for elegant projection, her grace and her ease in the public at all times what she would become. It was not until 1803 that her first marked success had been obtained. In that year the part of a dead and dumb pupil of the Abbé de l'Épée, in the piece of name having been assigned to her by the author, became by her talent and grace in its performance, that from that night she took rank as one of the great comic actresses. Her talents rapidly increased under the influence of cordial encouragement. Her kind instructor, Mademoiselle Contat, took leave of the stage in 1809, leaving the inheritance of her 'réciters' to be divided between Madeemoiselle Mars and Mademoiselle Levard, which gave rise to a long contest between the rival stars. The former however soon distanced the latter completely, and she acquired such fame as the head of all French actresses in genteel comedy, gaining a new success in every new part, down to that of Mademoiselle de Belle-Isle, in Dumars's drama, which she played for the first time on the 2nd of April, 1839, when she had passed the age of three-score.

Yet, although she never refused to take the leading characters in plays of the new school, and in each achieved a new triumph, she was to the last opposed to the modern romantics, and preserved the excellencies of her own parts. Victor Hugo and the elder Dumas were sometimes embittered by her criticisms and strictures, and the latter, in his 'Mémoires,' has described some piquant disputes of this nature between the actress and the dramatist. She had a decided individuality, but her grace, her wit, and especially the manner in which she could breathe life into the head of all French actresses in genteel comedy, gaining a new success in every new part, down to that of Mademoiselle de Belle-Isle, in Dumars's drama, which she played for the first time on the 2nd of April, 1839, when she had passed the age of three-score.

died on the 20th of March 1847, her death having been accelerated, if not caused, by the habit of having her hair dyed every ten days. She left behind her a fortune of 60,000 guineas.

MARSHALSEA. The Court of the Marshalsea and the Palace Court were abolished by the statute 12 & 13 Vict., c. 101. Their procedure and the costs of actions therein had for some time been before the object of animadversion by writers in pamphlets, and the long delay, hitherto, had amounted, amounted to no more than the universal complaint of the costs incident to legal proceedings. The Palace Court had not long before been reputed by Royal Commissioners to be one of the best in the metropolis.

MARSILICEAE, or RHIZOCARPÆAE, Pepperworts or Rhizocarps, a natural order of Aquatic Plants, with creeping stems bearing leaves, which are usually divided into three or more segments, and are often floating. The flowers are small and greenish. The rootstock is produced at the base of the leaf-stalks, and consists of sporocarps and involucres inclosing clustered organs, which consist of antheridian and pistillidan cells. The germinating body has an oval form, and occasionally a mamilla on one side, whence roots and leaves proceed. The species are all inhabitants of ditches or inundated places. They do not appear to be affected so much by climate as by situation; thus they have been detected in various parts of Asia, Africa, America, chiefly however in temperate latitudes. Their position is well described by Lycojodioae and Lycojodineae. The species number about 20, the principal of which are—Pulicaria, Marsilea, Acis, and Salvinia. (Balfour, Class-Book of Botany.)

MARTIN, John, or Martin, was born at a house called the Eastland Ends, Haydon Bridge, near Hexham, Northumberland, on the 19th of July, 1859. His early ambition being to become a painter, his father, as the best way of turning his desire to profitable account, apprenticed him to a coachmaker at Newcastle (whither the family had removed) to learn herald-painting. Here however he only remained a few months; and, his indolence having been canceled, he was sent back to school with the help of an Italian painter named Bonifacio Musso, the father of Charles Musso, who acquired some distinction as an easel painter. With him young Martin removed to London in September, 1860, and soon after, not getting on very pleasantly in his master’s family, took lodgings for himself; and, as he relates in some autobiographical notes contributed to the Athenæum (see Ath. for 1864, p. 246, to which we are indebted for the leading facts contained in this notice), “at this time, by close application to his studies, I began to draw; in the depth of the long winter, I obtained that knowledge of perspective and architecture which has since been so valuable to me. I was, at this time, during the day employed by Mr. C. Musso’s firm painting upon cloth and glass; by which, and making watercolour drawings and perspective, he made his way. The life I led in fashionable society was a struggle for an artist’s life when I married, which I did at nineteen.”

His marriage stimulated him to bolder course. He determined to paint a large picture, and by a mouth’s application produced in 1812 his first work, ‘Sadak in search of the Waters of Oblivion.’ Before it left his hands his hopes received a severe blow: he “overheard the men who were to place it in the frame disputing as to which was the top of the picture.” It was a must make an easy enough decision; once in the frame the top of the picture would not be again in danger of being taken for the bottom. It found a place in the Royal Academy Exhibition, and, what was better, a purchaser for 50 guineas, in Mr. Manning, a bank director. He followed up his success by sending to the British Institution an ‘Exposition from Paradise,’ and to the Academy in 1814 ‘Clytie,’ a work which hung in the ante-room, as well as in the main room, and more ambitious picture, ‘Joshua commanding the Sun to stand still in the Leaving of Jericho,’ which, as in the first instance, was exhibited the following spring, it was placed in a post of honour, and awarded the prize. Martin was excessively angry with the Academy for not being allowed to take his grand picture in the same breath and the breach was never healed: he removed his name from the Academy’s books as a candidate for membership, and as a necessary consequence, according to the laws of the Academy, he never received any academic distinction. With the picture itself, and the success it met with, he was, however, abundantly satisfied. “The confidence I had in my powers,” Martin writes, “was justified, for the success of my ‘Joshua’ opened a new era to me. In 1818 I removed to a superior house, and had to devote my time mainly to executing some immediately profitable works; but in 1819 I produced the ‘Fall of Babylon,’ which was second in value of all my productions. Its exhibition excited the attention it excited. The following year came ‘Macbeth,’ one of my most successful landscapes; and then, in 1821, ‘Belshazzar’s Feast,’ an elaborate picture, which occupied a year; and I received the premium of 3000l. from the British Institution.”

These works, and especially the ‘Belshazzar’s Feast,’ were of a kind then quite new, and took the London public by storm. A sturdy opposition was raised; but for the time it was best to ignore the opposition. The ‘Belshazzar’ was swelling with success, loudly declared—and pretty widely believed—that a new era was opened to art, as well as to the painter’s self; and the engravings quickly made the artist’s “sublime style” as a subject of conversation. Martin was slow to follow up his success: “The Destruction of Heroden came in 1822; the ‘Seraphim’ and the ‘Paphian Bower;’ in 1824, the ‘Creation;’ in 1826, the ‘Deluge;’ and in 1828 the ‘Fall of Nineveh,’ perhaps the most popular of all his pictures after the ‘Belshazzar.’ He was now, however, so much engrossed with engraving, and with various schemes for the improvement of London, and other engineering projects, that for a while his pencil was somewhat less diligently employed, and when he resorted to his brush it was not so often on a large scale. His later pictures indeed found admirers, but they were few as compared to those which greeted his earlier works, and infinitely less enthusiastic. Yet he went on to the last painting of his life with as much zeal as was necessary to captivate the public eye. Thus during the last twelve or fourteen years of his life he painted—‘The Death of Moses,’ and ‘The Death of Jacob,’ 1838; ‘The Eve of the Deluge,’ ‘The Ascenting of the Waters,’ 1840; ‘The Conquest of City and River of Babylon,’ and ‘Pandemonium,’ 1841; ‘Flight into Egypt,’ 1843; ‘Christ stilling the Tempest,’ and ‘Canute the Great: breaking his Courtiers,’ 1843; ‘Morning,’ and ‘Evening,’ 1844; ‘The Judgment of Adam and Eve,’ and ‘The Fall of Man,’ 1845—lively and picturesque visions, and ‘Zéglé in the Happy Valley,’ 1849; ‘The Last Man,’ 1850; ‘Valley of the Thames viewed from Richmond Hill,’ 1851.

The last picture he exhibited during his life was a ‘Scene in a Forest—Twilight’ (1859). He was now engaged on a series of three grand paintings, illustrative of the ‘Last Judgment,’ which he fondly hoped would be his master-work, and he laboured steadily at these till a few weeks before his death. He had recourse to no means to hasten his work. He lived in the hope of improving his health to Jouglass, Isle of Man, where, at the house of Thomas Wilson, Esq., he died February 9th, 1854. His remains were interred in the lonely cemetery of Kirk Bradden, on the Strang Road, a few miles from Douglas, and on the 17th of September there was performed his funeral service in the church of St. Martin’s, Wirral, and ‘The Plains of Wrath,’ and ‘The Plains of Heaven,’ have since his death been exhibited in London and the provinces. As might be expected from the nature of the subjects, and the circumstances under which they were painted, suffering under the infinities of age, with mind and body both enfeebled, they are comparative failures, having all the worst faults and manerisms of the painter’s earlier pictures, and only few of their redeeming excellences.

Martin was an original painter, and possessed a very considerable share of imagination; and in the expression of material grandeur and terror,—the vastness and might of nature, in contrast with the weakness and littleness of man,—he was eminently successful. At least until by repetition the conception had been worn out, the conception of the sublime was unimpressive, this was unquestionably the case; and the unparalleled popularity of his early pictures, while the manner was new, can be readily understood.

Martin died on the 28th of August, 1854, in his fifty-seventh year. He was a small man, with a very red face and a capital laugh; bear often repeating; and he kept on covering acres of canvases with interminable vistas of buildings, pile upon pile, as buildings novel could have existed in reality, and crowding the roads and fields with myriads of little insignificant figures, all treading down the whole in their progress through a twilight, with flashes of jagged lightning or streams of dazzling sunshine; never advancing beyond a harsh and niggling touch, or attaining to anything better than a crude and conventional system of colour. Seeing but two, or at most three, of his pictures, he might be pronounced a man of
MAR

MEE

genius; seeing all, while acknowledging his talent, it is difficult not to feel surprise at his deficiencies of taste, observation, and judgment.

It has been said that during many years the subject of the improvement of London occupied much of his time and thought. As early as 1826 his ideas had taken a definite shape, and he gave them to the public in a 'Plan for supplying with pure water the Cities of London and Westminster, and improving the western end of the metropolis,' and he continued over the north of the United Kingdom, up to the time of his death. The following is his own account of his labours in this line, contained in his contribution to the 'Athenaeum' already referred to: 'My attention was first occupied in endeavouring to procure an improved supply of pure water for the inhabitants of the metropolis, and in rendering it available as manure; and in 1817 and 1826 I published plans for the purpose. In 1839 I published further plans for accomplishing the same objects by different means, namely, a weir across the Thames, and for draining the marshy lands, &c., &c. In 1835, 1836, 1838, 1842, 1843, 1845, and 1847, I published and republished additional particulars, being so bent upon my object that I was determined never to abandon it, and though I have reapplied no other objects, and now, of course, coal mines, floating Harbour and Pier; iron ship, and various other inventions of comparatively minor importance, all conducing to the great end of improving the health of the country, increasing the produce of the land, and furnishing employment for the poorer part of the community.' He also took out patents for water and sewer-pipes, &c.

Besides his great pictures, Mr. Martin painted a great number of water-colour landscapes, very elaborately wrought out; he also made some drawings for books, including 'Paradise Lost,' and 'Paradise Regained,' the 'Pilgrim's Progress,' &c., for which he received large sums, but which, though popular in their day, now seem for the most part strangely insignificant as illustrations. For the Millon illustrations he is responsible for most of the work of 1805.

MARTINSIDE, a Mineral, which is composed of 91 per cent. of chloride of sodium and 9 per cent. of sulphate of magnesia. It comes from the salines of Haslum. (Dana, Mineralogy.)

MATHIEU, THE REV. THEOBALD, the Apostle of Temperance in Ireland, was born at Thomastown, county of Tipperary, October 10, 1790. His father, an illegitimate member of the family of the earls of Llandaff, died while his mother was young, and Theobald was enabled by the kindness of the Countesses of Llandaff and Lady Elizabeth Mathew, to proceed to the academy of Kilkenny, and afterwards to St. Patrick's College, Maynooth, where he remained until he was ordained a priest of the Roman Catholic Church in 1814. He was appointed to a missionary charge in Cork, where his influence was great among the rich and the poor alike: on his appointment to this mission he received from the pope, Gregory XVI., the degree of D.D., with a dispensation from the prohibition against ordaining a bishop, which Father Mathew conferred upon the inhabitants of Cork was the establishment of a religious society for the purpose of visiting the sick and needy, on the model of the societies of St. Vincent de Paul: this institution obtained the approbation of the Poor-Law Commissioners in 1834. About four years later he was requested to lend his aid to a temperance association formed in Cork. He joined the association and became its president; and devoting himself heart and soul to the peaceful agitation, he had the satisfaction to see within a few months no less than 160,000 converts in Cork alone. Extending his sphere of action he commenced a 'progress' through the west of Ireland, where poor and destitute results were seen; wherever he went the crowds that flocked to 'Father Mathew' to take the pledge of temperance were so numerous, that they could only be kept in control by the military and police. The same results followed in all the towns which he visited in the west of Ireland, at Dublin, at Cork, at Limerick, and at Ennis, and in Liverpool, Manchester, and London, where, regardless of creed and country, he went about doing good, and raising the squalid objects of pity and compassion to self-respect, independence, and industry. It ought to be noticed, that these visits were voluntary, and that he did not scruple to sacrifice his temporal prospects; a distillery in the south of Ireland which belonged to his brother, and formerly provided him with almost all his income, being cut up in consequence of his preaching against the use of ardent spirits. His services in the cause of morality and religion having been recognised by statesmen of all shades of opinion, her Majesty granted to Father Mathew out of the civil list an annuity of 300/. a year—a sum, though small in comparison to his labours, but sufficient to keep up the payments on policies of assurance upon his life obtained for the sake of securing his creditors; and a private subscription was entered upon for his assistance. He died on the 8th of December 1856: having from the state of his health been for some years incapacitated for active labours.

MAYACACEE, Mayaca, a natural order of Endogenous moss-like Plants, creeping over damp places, with narrow leaves, resembling Spider-Wort, but differing in the 1-cell'd anthers, carpels opposite the inner divisions of the perianth, 1-cell'd ovary and capsule, and parietal placenta. The species, four in number, are natives of North America. They are of no known use. (Balfour, Class-Book of Botany.)

MAYO, HERBERT, M.D., a distinguished medical writer, whose works on Physiology, although now to some extent superseded, were in considerable advance of his time. The first by which he made himself, but differing in the 1-cell'd anthers, carpels opposite the inner divisions of the perianth, 1-cell'd ovary and capsule, and parietal placenta. The species, four in number, are natives of North America. They are of no known use. (Balfour, Class-Book of Botany.)

Sepsis in Hindustan. From Meenur the mutineers marched
direct to the city of Delhi, where they were joined by
others. The aged nominal King of Delhi was pro-
claimed Emperor.
MEHMET ALI, Pasha of Egypt, was born in the town
of Cavaillé, in Roum-lí, about the year 1799. He began
life as the keeper of a small town; but having
volunteered into the army, he gained the government of
the governor of Candia by his zeal in suppressing a rebellion
of the pirates of that island. In 1799 he headed a contingent
of 300 Candian soldiers in an expedition to Egypt, where he
counts his success with the force of the native religion of
the French. Here he laid the foundation of his military renom-
and of his political ascendency. On the evacuation of Egypt
by the troops of the Emperor Napoleon I., the Sultan nomi-
nated, as viceroy of Egypt, Mohammed Khoren; but the
Mamelukes, in rising to assert their ancient rights and
influence, of which they had been deprived during the
occupation of their country by the French, chose Mehemet
Ali as their viceroy. In 1800 he was made Pasha of Cairo,
in which the following year was added the Pashalik of
Alexandria, as a reward for his services rendered to
the Ottoman Empire. No sooner however had he gained this
pitch of power than he turned against his old confederates
the Mamelukes—470 of whom he murdered in the citadel of
Cairo. There are numberless instances of his excesses
through the country: an end was thus put to a turbulent
and formidable race which had kept Egypt in a state of
anarchy and war for upwards of 400 years. After
the destruction of the Mamelukes, Mehemet Ali made himself
master of Egypt, which he held with an iron hand.
He obtained the government of that part of the country, the revenue of
which he considerably increased by raising the land-tax and
the custom duties on its internal trade. In 1811 he was sent
against the_currant, where he and the Mamelukes
were defeated, but had pillaged the holy cities of Mecca and Medina, and
whom he subdued after six years of constant warfare, and at a vast
sacrifice of men and money. When the Greek insurrection
against the Porte broke out, he offered to take part in the
rebelling nation; but his fleet in 1824, under Lalla
Moras, in the summer of 1824, under Ibrahim Pasha,
who however was obliged to retire after the battle of
Navarino in 1827. In 1830 the administration of the island
of Candia was confided to Mehemet Ali; but he had greater
schemes in his view. He aimed at obtaining possession of
Syria; and pleading as an excuse his desire to recover pos-
session of some Egyptians who had settled in that country,
he invaded Syria, with a large army under Ibrahim Pasha,
and obtained a commission to govern the same, which was
an integral part of the Ottoman Empire; but the
Viceroy of Egypt could not remain content with his own vice-
regal territory; and peace was only made between the
viceroy and the sultan [Manuwa II.] by the interference of the
Porte in 1833. Syria was annexed to the Ottoman Empire
by Mehemet Ali on his acknowledging himself a vassal of the Porte.
He remained in quiet possession of Syria as well as Egypt until
1839, when his nominal master, the Sultan, jealous and
weary of the way of so formidable a rival, sent an army and
fleet to expel him from Syria; and when he found that this
was impossible, he sought and obtained the co-operation of
England and the other European powers. In the summer of
1840 the combined fleets appeared before the coast of Syria;
in the autumn of the same year the Egyptian army was
defeated near Beyrut, and both that city and Acre
were captured, and Alexandria itself blockaded. Mehemet Ali
was obliged to come to terms, and abandoned his claim to
Syria, on condition of the Pashalik of Egypt being made
hereditary in his family. He continued to administer the
affairs of the country until September 1845, when he resigned
the reins of government into the hands of his son Ibrahim
Pasha, on whose death they passed to Abbas Pasha his
great-nephew. Mehemet Ali himself lived only a few months
after these changes, as he died August 2, 1840, at the age of
about eighty years. By his wives and concubines he had
sixteen children; two of his sons he sent to Paris for the
sake of education. He was buried at Cairo with great pomp
and honour.
Mehemet Ali was tolerant in matters of religion to an
extent rarely known among Mohammedans. His constitution
was strong, his stature short; his features, though dark and
stern, were expressive, and very ambitious, yet particularly sensitive to the opinions formed by others
as to his public policy. His government has been extra-
vagantly praised by some writers: but it certainly was more
rational, orderly, and enlightened than that of most of the
Mohammedan states of the East. He established order, partiality, established police and law-courts, abolished
torture, and encouraged education. He did his best to
remove the prejudices felt by his countrymen against the
administration of the law and his government of the country.
He introduced justice with
vigor, and such a wise and just measure, his government was essentially despotic and
absolute; and in order to support the expenditure necessary
to maintain the institutions already mentioned as having
been introduced by him, he was obliged to have recourse to a
heavy revenue, taxation, and for his army to an enormous con-
scription.
Upon the whole, however, it must be admitted that the
Albanian peasant was in his day a great benefactor not only
to his country but to society at large. Gifted with an
admirable talent for organisation, he introduced into one of
the most neglected and disorganised of countries the first
conditions of a civilised state, order and security, to such
an extent that it is said that a traveller, laden with gold, "could
sail up the Tigris and down the Euphrates without being
stopped by the Tartars to the frontiers of Abyssinia, between
sea and Nile and desert." In the administration of justice and
the general management of his empire he introduced more of
justice and settled principle than exists at the present time in
any part of the world. His internal administration, his
laws, and even his costume, awakened that beneficial spirit of industry which for many a long century had lain
dormant in Egypt. He first called into life the cultivation of
cotton, indigo, and sugar, which has since been pursued
with increasing success—a large portion of the produce
being being carried to the northern ports of his dominions, in factories erected
for that purpose at his expense. At the same time he gave
he great impetus to the cultivation of silk in Syria by the
plantation of mulberry-trees on an extensive scale. He
founded a system of national education, of which no one for
centuries past had conceived the idea in the East, and he
devised immense sums to that purpose. In fact he projected
and founded more useful institutions than any Egyptian
ruler since the days of Saladin. In addition to this, though
he provided for his own safety without a ship or a drifted and disciplined soldier, he found means to build a
fleet and to form an army trained after the European fashion.
Such are the means by which the Albanian peasant, who
only learnt to read in his thirty-fifth year, and who often,
in the words of the poet, "went without art or learning", to
head in safety, became a powerful prince, who twice made
the Ottoman Sultan tremble on his throne at Constantinople,
and whose personal energy and public importance gave him
a place among the potentates of the earth.

MELAMINE. [CHEMISTRY, &c.]

MELAMPYRINE. [CHEMISTRY, &c.]

MELANOSPERMEÆ, or FUCALES (Harvey), the first
sub-class of the class Algae. It consists of plants of an
olive-green or olive-brown colour. Phycitisation monocious or
dioicious; spores olive-coloured, either external, or contained
singly, or in groups, in proper conceptacles, each spore
enveloped in a transparent skin (perispore), simple, or
finally separating into several spores; antheridia, or trans-
parent cells, filled with orange-coloured vivacious corpuscles,
moving by means of vibratile cilia. It includes the follow-
ing orders:

Phaeahæ.—Spores contained in spherical cavities immersed in the frond. [Fucaceæ.]

Sporocistisæ.—Spores attached to external jointed flan-
ments, which are either free or compacted together in knob-
like masses.

Laminæsæ.—Spores forming indefinite cloud-like
patches, or covering the whole surface of the frond.

Dictyonæsæ.—Spores forming definite groups (sori) on the
surface of the frond.

Chondriæsæ.—Frond cartilaginous or gelatinous, con-
posed of vertical and horizontal filaments interlaced together.
Spores immersed.
The Orthidea—
1. Clytea.
2. Collecta.
3. Eucnemis.

MELITTHS, a genus of plants belonging to the natural order Labiata. It has anthriscus approaching in pairs and forming a cross bursting longitudinally. The upper lip of the corolla flat, entire, straight; lower lip with 3 rounded nearly equal lobes; calyx membranous, bell-shaped, ample, variously long and broad. M. Melittisphyllum, Basset Balm, has oblong, ovate, or slightly cordate leaves. The upper lip of the calyx with 2 or 3 teeth; flowers purple, with a white margin, or variegated of different sizes, large. Brem 1 or 2 feet high. M. grandiflora (Smith) is the largest variety. They are both found in woods in the south of England.

MELKSHAM. [Wiltshire.]

MELOSIRENE, a family of Distosieae, formed by Kützing. The species are ston. not having a central opening on the secondary side. The stamens are interrupted in the median line. It includes the genera Galioneola, Melosira, Potosira, and others. Meneghini, in his "Natural History of Distosieae," makes the following critical remarks on this group:

"The Melosira in general may be regarded as polyplorphic associations of Cyclorella, and the comparison precludes principally in the second sub-genus. The distinction of the two sub-genus is also proposed by Hassall (Spergularia, Melosira) in the Sphaerastrum, but it is a species flora flat at Point Gellibrand, on the west side of Hobson's Bay, about 8 miles S.W. from the city. It contains some good houses. A railway connects Williamstown with Melbourne city. By means of a pier at Williamstown, having a communication with the railway termini, passengers and goods may be landed and sent to Melbourne.

MELDRUM. [Aberdeenhire. S.]

MELILLA, a sea-port town of Marbella belonging to Spain, is situated 11 miles S. from Cape Ras-ad-Dir, or Tres-Focos, in 36° 15' N. lat., 6° 25' W. long., and has about 2000 inhabitants. The town stands on a peninsula about 40 feet above the sea, and united to the mainland by a rocky isthmus. Melilla is one of the Spanish presidios on this coast. It is improvement on the land side, and towards the sea, it is defend by strong ramparts. The fortress has large magazines and citernes, and small vessels can enter the harbour. The presidios of Peñon-de-Velez and Alhucemas, or Alhucemas, two strongly fortified rocky islands between Cape Tres-Focos and Melilla, are also under the same title. The Spanish garrison of Melilla numbers about 1000. The rest of the inhabitants are for the most part convicts and exiles. Melilla is said to derive its name from the Spanish word for honey, which is gathered of superior quality on the mountain slopes along this coast.

MELISSAC Acid. [Chemist. S. 2.]

MELISSACE. [Chemist. S. 2.]

MELITTA (Kirby), a name for a genus of Insects belonging to the order Hymenoptera, and to the tribe Melitfera of Latreille. The genus as originally constituted by Kirby embraced all the Honey Bees known at that time. This genus is now split up into numerous smaller ones. Leach divides the Melitifer into two families, Andreienis and Chrysidia.

The Andreienis include the following genera:

1. Coleopta.
2. Porphria.
3. Pseudepida.
4. Pseudepida.
5. Hylitusa.
6. Hylitusa.
7. Pseudepida.
8. Pseudepida.
11. Hylitusa.
13. Hylitusa.

During desiccation it happens in the marine species, as in the _Podostrea_ already described, that the internal substance adheres to the inner wall in the form of oily globules surrounding the spermatangial or carpogonial margin, and compresses one against another in the form of regular polygons. Ehrenberg also speaks of diaphanous vascular spaces, which he regards as stomachs. Küttning enumerates, figures, and describes nineteen species, marine, freshwater, and fossil, between which he places one genus at the end, and a famous _Ferruginea_ (M. ocrasiera, Rafs), which he proves not to belong to the class of _Diatoameae._

We shall find, as a character common to them all, the circular figure of the vertical section parallel to the lateral surfaces; a character which, as well as the other, of a radiated disposition of the striæ upon the lateral surfaces, we shall find repeated in the family of _Cocceidioætes_, which, having the shield of a cellular structure, belong to the tribe of fungi to be constantly regarded so the _Melostrea_ (endota, decussata, irrigata), to be furnished with the same organic condition, and hence arises a fresh doubt respecting the systematic value that has been ascribed to it.

In general we may also say, that in the _Melostrea_ the development of the lateral surfaces prevails over that of the primary ones, which we find finally to disappear in certain genera (_Podostrea_, _Cocceidioætes_), as well as in some species of _Melostrea_ (varria, orichalcea), the increased length of the axis, and the concave or convex condition of the primary surfaces: and it is to be observed, that although in this family the primary surfaces differ precisely as much in form as they do in the three preceding ones, yet we find in these the same organic character as in the greater number of the former groups, only the presence of longitudinal furrows or canals. The separation of one lateral surface or valve from the other, with the consequent dilatation of supericies, which the primary surfaces exhibit before the duplication takes places (though verified to some degree in other genera, yet in the _Melostrea_ better than elsewhere), presents an undeniable analogy with the reduplication of _Demeisadæta_, which Brébisson distinguishes from the deduplication of _Diatoameae_. The particular disposition of the internal radial or mural canals, determining the section of the centre, the arrangement of some articulations, and the dilatation of the interstitial ring, are isolated facts, which however merit particular attention in the paeony of our knowledge.

**MENACANITE.** [Titanium.]

**MENETHIUS.** [Maiden.]

**MENDELSOHN,** _Felix Mendelssohn-Bartholdy_, one of the greatest musicians of the present century, was born at Berlin, 3rd of December 1809; he was the grandson of the celebrated Moses Mendelssohn. His father, who was the head of a great banking-house, on his marriage adopted the name of his wife's family in order to belong to his own. He had embraced the Lutheran faith, in which he continued to die. When Felix was in his infancy, his father removed from Hamburgh to Berlin, where he resided till his death, enjoying a distinguished place in the society of the Prussian capital. He bestowed the utmost care upon the education of his son, who showed, at a very early age, singular attainments, not only in the art to which his genius especially directed him, but in various branches of literature and science. While yet a child, he gained the affections of Goethe, who was a friend of the family; and the published letters that anonstrous man contain many touching expressions of his love for the youthful Felix and prognostications of his future greatness. He was even then remarkable for his amiable disposition and simplicity of mind, in which he retained unimpaired to the end of his short life.

In the case of almost every great musician—of almost every great artist: indeed of any description—Mendelssohn's genius showed itself even in infancy. He tried to play almost anything he could speak. He was the best and earliest culture. Zelter, the friend, and correspondent of Goethe, was his chief instructor in music, and his progress was almost as marvellous as that of Mozart. Indeed his first work, which was published, was in advance of anything produced by Mozart at an age equally tender. His three quartets for the pianoforte, violin, and violincello, written before he was twelve years old, are not merely surprising juvenile compositions, but masterly works, which continue to hold their place among the classical music of the age. He was in his sixteenth year when his opera, 'The Wedding of Camacho,' was produced on the Berlin stage, more, it has been said, from the wish of his proud and happy parents than his own, and the public always took a part of the interest of this more popular character. It was favourably received; but, as it betrayed some inexpediency in composition for the stage, it was withdrawn by his friends. It was however published; and, though it is not generally known to the public, many copies of it have been sold, and it is one of the most charming, but full of the dramatic element. Every personage speaks in his own characteristic language, from the solemn pomp of Don Quixote and the grotesque humour of Sancho, to the grand narrative of the love of the hero, and the wedding and its crosses form the subject of Cervantes' delightful story. This most interesting piece shows what great things Mendelssohn might have done for the music of the stage, had he not left this branch of his art to tread the highest of all—that in which he followed, and with a still greater distance, the footsteps of Handel. Another proof of the dramatic character of his genius at that early age was the composition of the overture to 'The Midsummer Night's Dream,' which breathes in every bar Shakespeare's own inspiration. Its popularity has now become unbounded: and no listener can fail to trace in its passages, in which the fanciful, the delicate, and the grotesque are so exquisitely blended, the various conceptions of the poet. The rest of his works was written till many years afterwards, for the purpose of accompanying the performance of the play at Berlin. Its effect, thus introduced, was found to be so delightful, that in Germany the play is never represented without it, and the same effect has been produced in England.

Mendelssohn had just reached his twentieth year when he made his first visit to England; a visit which deeply influenced the course of his life. He arrived in London in the autumn of 1828. The day was dis remembered that he and his family were received at our most eminent musicians, by whom he was cordially received. At the first concert after his arrival of the Philharmonic Society, his overture to 'The Midsummer Night's Dream' was performed, and received with enthusiasm by an audience not improperly composed of those who could never have heard of him. It was immediately published. In a little memoir of his life, published a few years ago by Mr. Benedict, the eminent German musician so long resident among us, there are some valuable reminiscences on his London début. "The effect," says Mr. Benedict, "of the first performance of the overture to 'The Midsummer Night's Dream' in London was electrical. All at once, and perhaps even when least expected, the great gap left by the death of Beethoven seemed likely to be filled by the presence of another genius in the world; in 1828." That was the birth of the much underrated taste of the English public, and its discernment in appreciating and even discovering new-born musical talent. Not to speak of the Elizabethan era—of Orlando Lasso, Luca Marenzio, the great madrigal writers—there was a generation of Englishmen who could never have heard of him; and it was not until he came to perform in England and for an English audience! Were not Haydn's finest symphonies written to gratify the London amateurs before a note of them was heard or known in Germany or France! Was not Beethoven known and revered by English artists, by English musical societies, when almost forsaken and neglected in Germany! And so it was with Mendelssohn. His renown, after the enthusiastic but just reports of his reception in London, both as a composer and pianist, spread to those who were all the Europe, and gave the young and ardent maestro a new stimulus to proceed on this glorious path.

In the same year Mendelssohn visited Scotland. In Edin-}

burgh he was warmly welcomed by a literary and musical society, able to appreciate his genius and achievements, and his stay in that city was always regarded by him as one of the most agreeable incidents of his life. He afterwards made an extensive tour through the Highlands and the Western islands, receiving everywhere the highest adulation. His excursions of the days spent in Scotland are to be found in his writings. He was deeply impressed with the wild and romantic beauty of the old Caledonian music, even in its rudest and most primitive form, and especially admired the Highland bagpipe and those strange instruments which receive their name from "polo," and scarcely allowed by dainty connoisseurs to deserve the name of music, yet reach the heart of every true Scotman. Such music Mendelssohn could understand and value. A Scottish friend carried him to witness the "Competition of Pipers," as it is called, a gathering of masters of
the national instrument, who are chiefly retainers of great
families, and assemble annually in the Edinburgh theatre to
counterbalance the Sacred Harps. The most brilliant com-
petitor of the metropolis—a relic of Scottish feudalism still
preserved. To the surprise of his cicerone, who merely wished to give him half an hour's amusement,
Mendelssohn remained to the last, immersed in what he
heard, and the admiration and the enthusiasm of the
congregation, and the powers of the performers. Many
years afterwards, the same friend heard the celebrated symphony
in A minor (now called the Scottish symphony) performed
for the first time in the presence of the composer, and
his first orchestral piece too, 'The Isles of Fingal,' is full of the
impressions made upon his mind by the wild and stormy shores of
the Hebrides.

In the following year he was for some time in Italy; and
two years afterwards he visited Paris. From thence he came a
second time to London; and from that time, we believe, to
the end of his life, there was scarcely a season in which he
did not visit England. He began even then to feel that he
was in a country of his own; and therefrom England became, as it were, his adopted
country, and was associated with the most important circum-
stances of his artistic life. His treatment at that time by
his own countrymen appears to have inspired him with dif-
fidence; for, as he says, 'My name became a household
word' in Germany, and men ran away from one another
saying, that "the mean cabals which were always at work
against him at Berlin increased his dislike to that city so
much as to induce him to leave it, as he then thought, for ever,
and settle in London, for the sake of being free from
the directorship of the famous Gewandhaus Concerts, and
where he remained till the year 1844, when he was induced, by the
pressing request of the King of Prussia, to return to
Berlin.

His entrance upon his glorious career as a composer
of sacred music may be fairly ascribed to the committee of
the Birmingham Festival; for he set about the composition of
his first oratorio, 'St. Paul,' under the arrangement that it
should be performed under his own direction at the festival of
1837. And it was so performed accordingly, having been
previously produced at Düsseldorf and Leipzig.

The performance of this oratorio in the Town-hall of
Birmingham on the 20th of September 1837, was an event
memorable for the wonderful upsurge of the musical
feeling which it showed. The whole town was in a ferment
up with the unrivalled magnificence for which the musical
festivals of that town are distinguished. The impression
which it made upon an immense assembly will long be
remembered by those who were present. Mendelssohn was
again the instrument by which this successful event was
achieved; for "The Hymn of Praise," composed expressly for that
festival, was performed under his own direction. This
remarkable work, called a 'Sinfonia-Cantata,' in which the
powers of vocal and instrumental music are equally employed
in developing a grand design, had a great success, and like
' St. Paul,' was speedily reproduced in the metropolis, and at
all the great music-meetings in the kingdom.

His third and last oratorio, the greatest of them all—
'Elia,' was also written expressly for Birmingham. Though
he undertook it immediately after the production of 'St.
Paul' in 1837, it was not performed till 1846: and during
these nine years, it occupied a large share of his thoughts and
his labours. When the time for its production drew near, he
resolved to return to Berlin, and gave up every other occu-
pation, in order to devote his whole powers to this work.
The poem, in which the principal events in the life of
the Hebrew Prophet are related in the language of the Bible,
was constructed by Mendelssohn himself, and the English
version was also adapted to the music with admirable
skill by Mr. Bartholomew. The first performance took
place on the 26th of August 1846, the performance being
conducted by the author. The enthusiasm it excited cannot
be described. It was as white and as grand in voice, as to
be not only the masterpiece of the composer, but the greatest
oratorio given to the world since 'The Messiah:' and this
judgment has ever since been strengthened and confirmed,
not merely by the opinions of connoisseurs and critics, but
by the united voice of the British nation.

The production of this immortal work was the crowning
glory of Mendelssohn's career. He was again in London, in
1847, to superintend its performance at Exeter Hall by the
Sacred Harps. It was not performed there, and afterwards, under his own direction, at
Birmingham and Manchester. Soon afterwards he left England,
ever to return. His health had for some time been declin-
ing. Shortly after his arrival at home, he received a shock
which lay him low for the summer. When he recovered, he
was not the same man. He had changed in character and talents, and to whom he was fondly
attached. From this blow he never recovered. He was
persuaded to visit Switzerland, where, living quietly in the
isolation of his own house, he renewed his strength and returned
home to Leipzig, morally convalescent. But he soon
relapsed, and at length sank under his malady, an affection
of the brain, and expired November 4th, 1847, before he had
completed his thirty-ninth year. He left many manuscripts
of compositions, which are understood, were placed in the
hands of several eminent musicians, friends of his family,
with a view to selection and publication; but none of them
have been given to the world except a fragment of an
Oratorio, entitled 'Christus,' and some scenes of a romantic
opera. The suppression of all the others, some of which
were known to be works of magnitude and importance, has
excited much surprise and dissatisfaction.

In a sketch like this, it is impossible to speak in detail of
Mendelssohn's contributions to our musical life. They are
so many, so varied, and so allied to the very life of the
brave every branch of his art; but it was in sacred music
that his highest powers were displayed; and 'St. Paul' and
'Elia' will descend to posterity along with 'The Messiah'
and 'Israel in Egypt.'

Mendelssohn was exposed to none of the cares, struggles,
and vicissitudes which genius is too often heir to. Happy
in all his domestic relations, in the enjoyments and triumphs
of his art, and above all, happy in a pure mind and blameless
life, few men have had a more enviable lot than Felix Men-
delssohn.

MENY. [Bacterium anthracis, S. 2.]
MERCANTILE MARINE. [Shire, S. 2.]
MERCHANT-SHIPPING. [Shire, S. 2.]
MERE. [Wiltshire.]
MEMLANGUS, a genus of Fishes belonging to the family
Gadidae. It is distinguished from the genus Morhua, to
which the Cod-Fish belong, by the absence of the barbule
at the chin. [Mormula.]
M. vulgaris (Gadus vulgaris, Linnaeus), the Whiting.

This fish is so well known as to require little or no
description. It is distinguished by its dark coloration, and
its flesh. The pearly whiteness of its flaky muscles, added to
its extreme lightness as an article of food, recommend it
particularly to invalids as an article of diet. It is caught in
great abundance all round our coast, and may be traced
from the Shetland Islands to the Dogger Bank. It is a voracious
feeder, and seizes indiscriminately Molluscs, worms, small
Crustacea, and young Fishes. Though occasionally occurring
in the London market of three or four pounds weight, the
most usual size is from 16 to 16 inches in length, and weigh-
ing about one pound and a half. The body of the Whiting,
like the body of those belonging to this division, is longer
for its depth than that of the Cod-Fish; the scales small,
oral, and deciduous; the lateral line dark and straight pos-
teriorly, but rising gradually throughout the anterior half;
the head elongated; the mouth and gape large, the tongue
thread-like; the caudal fin small, and the other fins, pink
above the lateral line pale reddish-brown; sides and
belly silvery white; pectoral, caudal, and dorsal fins pale
brown; ventral and anal fins almost white, the pectoral fins
each with a decided black patch at the base and the black
above the lateral line pale reddish-brown. [M. adunus (Gadus adunus, Risso), Couch's Whiting.]

It is mentioned by M. Riss, in his volume on the 'Ichthyology of
Nice,' published in 1810, but was not caught in the British seas until 1840 by Mr. Crouch. His description is as follows: "a straight line 3½ inches; from the base of the dorsal fin to the vent along the curve, 3 inches; from the mouth to the edge of the gill-covers 3 inches; from the same to the anterior edge of the eye one inch; the eye large, the form a perpendicular oval; under jaw longest; the teeth very small, the snout receding from it backward, contrary to the form of the Whiting, in which the upper jaw is under a projection. The general form of the body resembles that of the Whiting, but rather more slender; the back rounded as if the specimen was tender, likely to be a result of emaciation. The distinctions between this fish and the Whiting are obvious, in the fins, fins, lateral line, colour, and vertebrae."

Catus carbonarius (Linnæus), the Coal-Fish. This is decidedly a northern fish, but being a hardy species, is not without considerable range to the southward. It was the only fish found by Lord Mulgrave on the shores of Spitbergen, and the fry, only 4 or 5 inches long, were caught with the trawl-net on the west coast of Davie's Strait, during the first voyage of Captain Sir E. Parry. It is found on the coast of the United States. It abounds in all the northern seas, and in the Baltic, and may be said to swim in the Orkneys, where the fry all the months of summer and autumn. As an article of food it is more prized when small than when of large size. The flesh of specimens weighing from 15 to 20 lbs. is usually dried or salted. This fish has more provincial names than any other fish, and generally when caught in a particular size. Among the Scotch islands the Coal-Fish is called Sillock, Plitlock, Coth or Ruth, Harbin, Cudden, Sethe, Sey, and Gray Lord. In Edinburgh and about the Firth the young are called Podleys; at Newcastle the fry are called Coalley, and when 12 inches long Bowdocks. The Coal-Fish may be traced on the Irish coast from Waterford along the eastern shore to Belfast. When detained and well-fed in a salt-water pond they attain a large size, and are very bold and voracious. The head and body are elegantly shaped, the dorsal fin and anal white and nearly straight; the upper part of the head and back above the lateral line almost black, much lighter in colour below the fins, becoming greyish-white with golden reflections on the sides and belly; pectoral, caudal, and dorsal fins bluish-black; ventral and anal fins greyish-white; the upper jaw rather the shortest, the lips tinged with purple red, the mouth black, the teeth very small, the irides silver white, the pellucine.

Catus Pollackius (Catus Pollackius, Linnæus), the Pollack. This fish is much less abundant on some parts of the coast than the Coal-Fish, but like that species is an inhabitant of the seas all round our shores. The fish is called Lythe in Scotland; it is a very plant activity, or from 'lythos,' a stone, in reference to its living in the rocky seashore, although its true nature is not decided. The Pollack is caught at Hastings and Weymouth, also in Devonshire, where it is sometimes sold as Whiting. When only 12 or 14 inches long it possesses a considerable portion of the flavour and delicacy of that fish. It is also caught along the Irish coast under the names of Pollack, Lath, and Lythe. The body is elongated; the upper part of the head and back above the lateral line olive brown, the sides dull silver white mottled with yellow, and in young fish spotted with dull red; the lateral line dusky, curved over the length of the pectoral fin, then descending and passing in a straight line to the tail; the dorsal fins and tail brown; the pectoral and anal fins edged and tinged with reddish brown.

Catus cirrus (Catus cirrus, Linnæus), the Green-Cod. This fish was first added to the list of British fishes by Sir Robert Cumfl, and is a distinct species, as some doubt it, is not only abundant, but has an extensive range. It is mentioned as a distinct species by Linnaeus and is taken on the coast of Scotland, the Isle of Man, and on the Cornish coast. By some it is thought to be the young of the Coal-Fish, and by others the young of the Pollack. There is no constant comparison between this fish and the Coal-Fish from the abundance of both, consider them as distinct species. It seems to combine in itself the colouring of the Pollack, with some of the peculiarities of the Coal-Fish, but appears also to be deeper in its length than either, though if the young of a large species, judging by analogy, that would not be the case. The subject in its present state is open to investigation, and invites the attention of those who are so located as to be able to explore the depths of the ocean. The species of both."

MERTENSIUS, a genus of Plants belonging to the natural order Boraginacea. It has a calyx of 5 deep segments; corolla bell-shaped, with a short thick cylindrical tube with 5 minute entire segments; filaments several, free, inserted quite beyond the throat; filaments elongate; style simple; stigmas smooth, inflated, rather drupaceous, attached laterally near their base by a flat surface; seeds free.

M. maritimum has a procumbent, branched stem; leaves ovato-elliptic, green, about 3 inches long, with stout, glossy, glaucous; nuts smooth; flowers in racemes, purplish-blue; pro- tuberances in throat of corolla yellow; leaves with a flavour resembling that of oysters; nuts free, forming a plum-like mass; calyx and petals small; perianth of the corolla smaller than the cavity. It is found on the northern shores of Great Britain.

M. oleracea. [Blackberies.]

M. ACIDIC NACH. [CHEMISTRY, S. 1.] MESITYLENE. [CHEMISTRY, S. 1.] MESITONE. [CHEMISTRY, S. 1.]

METEOROLOGY. To the article in the 'Penny Cyclopaedia' of this subject, of which we have supplied the investigation of the atmosphere as the physical medium between the earth and the heavens, may now be added some account of two or three important subjects, our acquaintance with which has recently been greatly improved.

Metcalf, Metcalf. The following is a condensed statement of the present condition of knowledge upon these subjects, which are connected in a remarkable manner with cosmical science, and with almost every department of physics and of the study of inorganic nature. They are connected to a great extent with the history of the origin of the earth, and the history of the atmosphere. It may be said that the history of science to which little attention has yet been given— the explanation and interpretation by means of our present knowledge, of the numerous relations of such phenomena which occur in ancient history, both classical and medieval, as well as in the popular historical literature of more recent periods.

The spaces through which the bodies of the solar system and the comets revolve about the sun, appear also to be traversed by celestial bodies comparatively minute, but in number incalculable; which, in common with the smaller true planets of the system have received from certain astronomers and physiicists the appellation of Asteroids, or Minor-Planets. In these little beings the history of the origin and ancient sense of any luminous object seen in the heavens. These smaller asteroids, when they approach within a certain comparatively small distance from the earth, are, or subsequently become, the objects termed shooting-stars, fire- balls, and igneous meteor; new series of phenomena being successively presented by them as they come nearer to the earth's surface, and especially in many instances, in consequence of their final passing through a great extent of the atmosphere in an oblique direction, so as to experience the effects of its increasing density, both physical and chemical, throughout a trajectory of great length. But in this general statement it is not pretended to deny that objects projected on the earth are different in their origin and nature, as well as from each other, as from those which we review, may probably be included also under the popular or only half-scientific designations of meteors and shooting-stars.

The appearance of these meteorites is in many cases attended or accompanied by the fall of solid bodies, either stones or metallic iron, or in some cases both mingled together in the same block, forming a series of bodies collectively termed Meteorites (or Arboletes, 'Penny Cyclopaedia,' consisting, mineralogically, of two principal groups, gradually inclining to each other in the atomic proportions of stony and metallic stones).

The visible meteor, when observed at those distances which must be within the atmosphere, and possibly indeed when at much greater, must consist of flame, or gaseous matter in an ignited or incandescent state, and undergoing combustion, butaring, may be inferred from Sir H. Davy's re-
searches on flame, not from the combustion of matter which under ordinary circumstances can exist in a gaseous state at the surface of the earth, but from that of matter which is there solid, consisting, doubtless, of the metallic or other combustible bases which meteors are found to contain. Among these it may be remarked are sulphur and phosphorus, both which Davy particularly as capable of combustion in air rared to a degree equal to that of the regions of the atmosphere in which they had been observed to discharge their phenomena. No particle of new matter whatever can be laid upon this circumstance, as meteors contain other combustible bases which very probably have the same property, including the metal magnesium, an element of almost every meteor which has hitherto been observed. The luminous intensity of light also which attends the combustion of magnesium in oxygen, may be connected with the brilliant phenomena of the meteors.

The luminous extensions in the direction opposite to that of the meteor’s motion, ordinarily called tails, as observed in many, if not in all igneous meteors, are manifestly referable to the elongation of the mass of flame constituting the visible meteor, by the resistance of the atmosphere to its progress through it. In the meteor’s path, of a kind some degree by the adhesion of the air to it; the passage from the intense white light of the head or body and proximate portions of the tail, to the red light of the distant and extreme portions of the latter, being attributable to the cooling done in the process of the perpendicular descent of its distance from the most intensely heated part of the meteor.

It would appear, both from theory and observation, that the figure of the meteors must approach in their course more closely to that of the solid of least resistance. The meteorites which fall, or are cast down from them, when unbroken, especially those consisting of metallic iron, retain approximately the form which had thus been imparted to them by the motion of the meteor. They fall through the air—a form resembling that of the more perfect volcanic bombs, and which they have received from the same cause. These effects of the resistance of the atmosphere to the meteor’s motion were first pointed out by Mr. Brayley.

The persistent track or trail of less vivid light often continuing to be seen for several minutes, or for a considerable fraction of an hour, or even for more than an hour, after the disappearance of the meteor itself, must be attributed to the deposition of the light, and is a kind of beam of finely divided solid matter,—mingled probably with vapour, and no doubt in part produced by the condensation of vapour,—resulting from the combustion proceeding in the meteor’s path, which has imparted enormous heat and energy to the light which was deposited at inassemblable distances from each other, continue to preserve, during their slow and uniform descent in the tranquil regions of the air, where they originate, the aggregate form in which they were deposited; while the slow conducting power of the air, as well as its ability to retain their high temperature and consequent luminosity for a comparatively long period of time. The continued action of gravity, and the disturbing agency of currents in the lower regions of the atmosphere, will, however, eventually convert the at first rectilinear beam into a more or less curved and waved figure, and at length produce the serpent of fire of the superstitious ages, accurately reproduced in the case of the meteor of the 7th of January, 1859, as reported by Mr. C. Smith, and quoted as a correspondent of the ‘Illustrated London News,’ of the 12th. These views are supported by telescopic observations of the trails, particularly those of the late Professor Pictet, of that left visible for seven or eight minutes by the meteor seen in France and Switzerland on the 15th of May, 1811, the most luminous part of which did not appear to be continuous, but composed of distinct and separate particles.

The production, continuance, gradual change of form and descent, and final dissolution of these trails, may be familiarly, but correctly, illustrated by comparison with the similar succession of phenomena characterising the trail of smoke and soot issuing from the funnel of a steam-ship during her passage. In the former case, the beam of finely divided solid matter separated from flame and smoke, and often several miles in length, becomes a persistent trail, and gradually changes into a waved or serpentine form. In many cases the trail of a meteor must have been originally a cylindrical beam, constituted as now explained, having a diameter of many hundred yards (equal to or greater than that of the meteor itself), and a length of many miles, deposited, in an inclined direction, at heights of some miles above the earth's surface.*

An objection founded on the assumed solidity of the particles, and the considerable specific gravity which must be attributed to them as results of the combustion going on within the meteors, which, it might be inferred, are inconsistent with the phenomena, is at once obviated by applying to the subject the results of Professor Stokes’s researches on the internal friction of fluids (noticed in the concluding division of this article) to the case of the meteors. It is evident that the fluid in a fluid of widely-different specific gravity, and to that of the suspension in the air the minute globules of water constituting the clouds. The trails of meteors are suspended like the clouds, though, at first, probably, in higher regions of the atmosphere, and like them they consist of excessively minute particles which, as in all probability their dimensions will be very nearly the same in all directions, may be regarded as sphaerules also, and will, consequently, be subject to the same law of the velocity of the globules of the clouds, by the resistance of the air toward the motion arising from the internal friction of the air. The degree in which they partake of the projectile motion of the meteor itself, will also tend to their longer suspension, by converting the friction of the air into a species of gravity which would cause it into an oblique curvilinear descent.

The two great causes of all the phenomena now described, are evident the motion and the heat of the meteors. The origin of the former is double, involved in that of the former, as to the nature of the meteors themselves, a subject noticed below. Dr. Chladni, the earliest philosophical investigator of the subject of meteors and meteorites (as a whole), and in later times Sir H. Davy and Sir John F. Daniell, have demonstrated by experiments on the compression and friction of the air, resulting from the enormous velocity, of from six to thirty miles in a second, or more, of the meteors, supposed to be solid when they enter the atmosphere. Still more recently, in a paper read before the Royal Society in 1854, Prof. P. G. T. Beauregard, Professor William Thomson have from their own experiments on the thermal effects of fluids in motion, to which those of solids carried through fluids must be equivalent, the great probability that meteors really acquire all the heat they manifest from the friction of the air.

In the present state of cosmical and meteorological science, it is unnecessary to enter upon the question of the origin of meteors and meteorites further than to urge, that, the complexity of the subject, and the extent and number of the visible meteors, however constituted, being often many hundred yards, while in some instances its dimensions must probably be expressed in miles,—their planetary velocity, and the planetary fact that they give out a more intense light than any other heavenly bodies, proves them to be of characters explicitly claimed by the writer of this article for the particular meteorites from which meteorites have been observed to descend, as well as for many, if not all of those from which their fall is not known), must at once disprove nearly all the hypotheses which have been framed specifically to explain the origin of meteorites; and especially, among others, that of their projection from lunar volcanoes. The cogency of this argument will remain essentially unimpaired even if it should be shown that there is in fact a continuous stream of meteors, or a constant probability of the actual magnitude of many of the meteorites is comparatively less than that hitherto ascribed to them. The problem of their origin must, in fact, be regarded as the same with that of the origin of the greater asteroids and planets themselves.

It is right to state that Mr. R. F. Proctor, who has given much attention to the subject, is of opinion that there is a distinction between luminous meteors and those from which meteorites have fallen; an opinion which, so far as the (apparently) smaller meteors, called shooting-stars, are concerned.

* These views of the physical constitution of meteors and their trails were in substance advanced by Mr. Brayley in a paper read in 1854 before the Meteorological Society of London, and published in the Philosophical Magazine, first series, vol. iv. p. 268, Dec. 1854, with the additions made in the present article, and with the thanks of the Society to him for permission to publish these views. These views have been subsequently repeated by him in lectures, together with the most recent details as to meteorological phenomena. The present article contains in a measure the result of these speculations.

The latter views, and the experiments described and graphically illustrated in a lecture delivered at a Nurses of the London Institution on the 18th January, 1856; in which also the subject of the partial trails of the meteors was more definitely explained.
cerned, he shares with the American Professor Olmsted, and others. Mr. Greg is the author of a valuable essay on meteors, entitled, 'Observations on Meteorolitics or Aerolites, considered Geographically, Statistically, and Cosmically.' The Catalogue of these falls was first published in the 'Philosophical Magazine' for November and December, 1854, and in a separate form in November of the following year.

The following are among the fallsthat have been enunciated in this article, have resulted from long attention to it by the writer. Others will be found, together with an invaluable assemblage of facts, in Arago's 'Astronomie Populaire,' liv. xxvi., 'Méteores Cosmiques,' tome iv. pp. 181-392; and also in the Report of the British Association, for some years past to the Reports of the British Association, by Professor the Rev. Baden Powell.

The last recorded fall of meteorites appears to have taken place in 1807, on the 29th of February, when two large stones fell at Parmales, in the Madure district, Madras, as related by the Rev. H. S. Taylor, in a communication to the Asiatic Society of Bengal.

The purely physical history of the subject having now been generally considered, we may proceed to notice the manner in which the extraordinary relations produced in former times, of the appearance in the sky of blazing torches, sceptres, bundles of rods, fiery swords, trumpets, and other objects, may be explained. It is generally thought that the phenomena for which the word meteor is used designate a particular class of phenomena known as meteoric phenomena. This subject belongs to a field in the history of science and literature, hitherto but little cultivated. It may be elucidated by examining the figures and accounts of such phenomena published in various works on astronomy, especially in those of Zahn, C. P. Wolfe, and others. The figures are, from their very nature, temporaries, and also by Ambrose Parey, and comparing them with similar phenomena as witnessed in more modern times, and depicted by observers whose only object was to represent the actual configuration of the luminous appearances. The circumstance that from the enormous rapidity of the meteor, all the visible phenomena (except the persistent trail) would have been seen and have ceased to appear with the limits of a few seconds of time (so that in all cases the figures must have been produced from memory alone), which must have led to the representation of many appearances as simultaneous that in reality occurred in succession, and the manner in which during the transit of the meteor, impressions on the retina of past phenomena must have been mingled with those actually present, have led to the production of many of the singular representations that are extant. It would not be difficult to trace the mental process by which natural objects, thus witnessed for a few seconds only, were forever fixed in the memory of the observer, and regarded with superstition, supposed to be really preternatural types of the familiar objects to which the outlines of their forms were comparable; the meteor, thus superposed, fixed in the mind's eye, and the like would naturally be described and depicted with all the approximations and paraphe-\nations of those objects. These accomplishments, however, were not in all cases merely suppositions, as may be evinced by reference to the great meteor of 1783, which em-\n\n\nabled the ringed sceptre of the medivial figures, the rings on the shaft being manifestly the smaller meteors, the production of which is the first visible result of the explosion, seen as projected upon the tail of the parent meteor; either because, as is evidently the case in many instances, they were really enveloped in the meteoric splendour it filled the air, and its glow on the account of the blinding upon the retina of the observer of past and actual appearances. The fiery sword dipped in blood is the meteor in its normal form, at the middle of its visible course, the distant part of the tail shining with red light, being cooled down to the temperature of simple igni-\n\ntion, as already indicated. In a similar manner, the bull's heads, flying-shears, and other monstrous appearances may be explained by the apparent position of the objects, the care being taken, when the authorities permit, to identify the phenomena correctly (otherwise otherwise recorded. The blazing and interlaced serpents, moving in the air may be explained by reference to the actual phenomena of the persistent tracks or trails already described, as witnessed in the reports of the Franklin institute, and other public representations of the meteor of January 7, 1826; one instance may be cited, in which a large and beautifully luminous serpentine train continued for some minutes after the disappearance of a meteor which threw down a stone at Angus, in 1822. The embattled tresses attached to blazing stars are evidently the trails under another phase, and in their later condition, emitting red light only, but retaining their linear or band-like form.

The Lepidopa columbina and Dracoma volantes of former ages, are understood, by reference to other characters and phenomena of meteors: one of the contemporary figures of the fire-ball seen in London on November 13, 1803, (described under other phases by Dr. F. Firminger in the 'Philosophical Magazine' for November 13, 1803) was a particular configuration of the meteor to which the latter appellation was given. This is contained in Nicholson's 'Philosophical Journal' for 1804.

From the latter division of the subject now summarily reviewed, an inference may be drawn, which though suggested also by other objects of science and literary history united—arises, it is conceived, in a particular manner out of the ancient history of Igneous Meteoric Stones. Meteoric stones, of any of the prodigious sights and supposed portents of moral or historical events, which are described in old chronicles and other works, may be explained, it has been shown, by our present acquaintance with the true nature of such phenomena. The inference is this—that the superstitious notions and ideas of preternatural manifestations and their signification, held in former times, were often found in mere ignorance of certain natural phenomena; and that there may be little either of superstition or intentional mispre-\n
\n\n\n\nunderstanding in the representations of those phenomena as they were employed in old chronicles, for the representations of later times, especially those of modern writers, have employed with much more accuracy observations they frequently include, and to separate them from the erroneous views with which they have been mingled; and thus to render the observations themselves, in numerous instances, available in the advancement of true knowledge.

Suspension of the Clouds. The most recent view of this subject, apparently a very simple one, but which really involves a variety of physical principles, is that of Sir John F. W. Herschel, stated in the following terms (Keeley. Brit. Ed. 8, vol. xiv. p. 635): "When the sun shines on a cloud, which absorbs its heat, the cloud itself is necessarily partially evaporated, and the vapour by its levity tends to advance an upward current, and thus to counteract the effect of gravity on the globules of which it consists. A globule of water 1-4000ths in. in diameter, in air of five-sixths of the density on the surface, or at the height of about 6000 feet, would have its gravity mitigated by a momentum of velocity of descent of one foot per second (supposing no friction and no draft); and even if the terminal velocity were reduced to half that quantity by these causes, would still require some such upward action to enable it to maintain its level—a circumstance which shows how far the actual condition of the suspended cloud of during the night. It is more than probable, however, that, when not actually raining, cloud is always in process of generation from below, and dissolution from above, and that the moment this process ceases, rain, in the form of 'mizzle,' commences. In a word, a cloud in general would seem to be merely the visible form of an aerial space in which certain processes are at the moment in equilibrio, and all the particles in a state of upward movement. To the phenomena of rain and snow must be required but an adequate estimate of the effects of the 'friction' and the 'draft,' which are supposed not to exist. But it appears to have escaped the attention of Sir J. Herschel, that Professor Stokes has already shown that the internal friction of the air, together, of course, by implication, with the 'draft' which it occasions, is itself one of the causes— in his opinion, indeed, the main cause,—of the suspension of the clouds. As this particular subject is new, and (as we believe) little noticed, it may be worth the while of others to pursue the inquiry for themselves (especially by reference to one department), of great importance in meteorology, we shall treat it at some comparative length. Clouds consist of an aggregate of separate minute globules of water; and the resistance to such a globule from the atmosphere with which it is surrounded is almost wholly on the cause just stated. 'Since the index of friction of air is known from pendulum experiments, we may,' Professor Stokes observes, 'easily calculate the terminal velocity of a globule of given size, neglecting
the part of the resistance which depends upon the square of the velocity. The terminal velocity thus obtained is so small in the case of small globules, such as those of which we are now speaking, as to allow of the air remaining undisturbed. In parent suspension the clouds do not seem to present any difficulty. Since in the case of minute globules falling with their terminal velocity the part of the resistance depending upon the square of the velocity is quite insignificant (as will presently be shown), compared with the part which depends on the internal friction of the air, it follows that the pressure equal in all directions in air in the state of motion (which according to the common theories of hydrodynamics, it would be), the quantity of water which would remain suspended in the state of cloud would be enormously diminished.

To render this view of the subject complete, and to explain the value of the last observation, it must here be stated that Professor Stokes had before shown that the fundamental assumptions of hydrostatics and hydrodynamics, that the pressure of a fluid is equal in all directions, though fully justified by experiment in the case of a fluid at rest, is not true in the case of a fluid in motion. The viscosity attributed to water by Dubruit and the inherent property "analogous to that of viscosity in liquids," ascribed to elastic fluids by Capt. (now Major-General) Sabine, from their respective points of view, and by Charles Hutton, and the results of an experiment of Stokes as consequences of the internal friction of fluids in general, all fluids exerting a resistance to bodies passing through them, independently of their density; and when this resistance is proportional to the velocity, there is no reason to doubt that the pressure cannot be equal in all directions.

The suspension of the globules of water forming the clouds, is only a particular case of the more general fact that fine powders remain nearly suspended in a fluid of widely different specific gravity. Professor Stokes has demonstrated that the resistance of the fluid, whether liquid or gaseous, is proportional, not to the surface, but to the radius of the sphere, and consequently the quotient of the resistance divided by the mass,—in other words, the accelerating force of gravity—becomes independent of the radius, and as the radius diminishes, than if the resistance varied as the surface: on which principle the suspension, or proximate suspension, of the particles or globules depends. When the downward motion of a globule is so slow that the part of the resistance which depends on the square of the velocity may be neglected, the terminal velocity of a globule of water forming part of a cloud may be determined. For a globule the one-thousandth of an inch in diameter, we have the velocity 2535 inch per second; for a half the diameter, the terminal velocity would be a hundred times smaller, so as not to amount to the one-sixtieth part of an inch per second.

Of that part of the resistance which varies as the square of the velocity, and which is the only kind of resistance that could exist if the pressure were equal in all directions, for the velocity 1593 inch per second, is not quite the one four hundredth part of the weight; and for a sphere only the one ten thousandth of an inch in diameter, the ratio of the resistance to the weight would be ten times as small. Both these proportions, it is manifest, are quite insignificant.

The conclusion thus arrived at by Professor Stokes as to the cause of the suspension of the clouds, illustrates in a remarkable manner the connection of different branches of science. It is an application by him of the theory of internal friction, as applied to the ball pendulum, and verified by recorded experiments on that instrument; and is contained in his memoir "On the Effect of the Internal Friction of Fluids on the Motion of Pendulums," published in the "Transactions of the Cambridge Philosophical Society," vol. ix. The erroneous extension of the fundamental law of hydrostatics has been denounced by the author of the velocity of Fluid Motion inserted in the preceding volume of that work, METHIONIC ACID. [CHEMISTRY, S. 2.]

METWOLD. [NAPOL.] METHYLMETHAN. [NAPOL.] MEYAMMA. [LONDON.] MEVAGISSY. [CORNWALL.] MEWER. [RAGTOPANA.] MEYER, SIR SAMUEL RUSH, K.H., LL.D., celebrated for his antiquarian knowledge, particularly in matters relating to ancient armour, was born on the 26th of August, 1783, and was the son of John Meyrick, Esq., of Great George Street, Westminster, and Peterborough House, Fulham, who was descended from the Meyricks of Bödorgan, Anglesey, and married a sister of Richard Jollif, of Queen's College, Oxford, but we have little other information of his early life, beyond the statement that he married about twenty years of age; and thus offended his father, who, in consequence of his inheritance of his family property, that it should chiefly pass to the next generation. It thus happened that the large collections of armour which were commenced by the subject of this notice at his residences No. 3, Sloane Terrace, and No. 20, Upper Cadogan Place, were neglected and, in the end, were known as those of Llewelyn Meyrick, Esq. The original intention as to property was however frustrated ultimately by the death of that son in 1837.

Samuel Rush Meyrick adopted the branch of the legal profession connected with the Chancery, Exchequer, and Admiralty Courts, in which, as Dr. Meyrick, he practised for many years. Prior to this, in 1810, he had published 'The History and Antiquities of the County of Cardigan.' In 1812, he was engaged upon a history of the plan of that of Dr. Henry, relating to the period of the monachies of the British blood, before their abolition in 703. The materials, which were collected for a work of great extent, were however not published in the form intended. But in 1814, with Captain Charles H. Fox, he published the "History of the Original Inhabitants of the British Islands," which was published in 4to with plates. His great work on Arms and Armour was published in 1834 in three 4to volumes, and under the title of the "Imaginary Armorial History of what existed in Europe, but more particularly in England from the Norman Conquest to the reign of King Charles II., with a Glossary of Military Terms of the Middle Ages." A new edition of this work appeared in 1843, under the care of Mr. Albert Way, with corrections, much improved in apparatus and quotations. Dr. Meyrick assisted the Rev. T. D. Fosbrooke in the compilation of his "Encyclopedia of Antiquities," of which the first edition appeared in 1826. In 1826, the authorship of Dr. Meyrick was sought in the arrangement of the collection of historical arms at the Tower of London ("Gentleman's Magazine," 1826, 1827): and in 1829 he was called on by George IV. to arrange the collection at Windsor. For these services, the Hanoverian order was conferred upon him by William IV. in January 1832, and he was made a knight-bachelor on the 22nd of February following. Meanwhile, about the year 1827, Dr. Meyrick had endeavoured to purchase the ruins of Goodrich Castle, on the Wye; but being then unable to succeed, he offered them to the Earl of Fife. In 1833, the Earl of Blore was the architect, and which is now well known as Goodrich Castle. The main part of the plan was arranged specially for the display of the collection of armour,—the whole suite a chamber, where a suit of armor was suspended a grand tournament. The chief scenes in the display are shown in a work published, by Mr. Joseph Skelton, F.S.A., in 2 vols. 4to. in 1830, and entitled "Engraved Illustrations of Ancient Armour," &c., to which Dr. Meyrick supplied drawings and descriptions. In 1834, when High Sheriff of Herefordshire, he revived a procession of the javelin-men in armour, and with medieval pageantry. In 1836 he contributed the descriptive matter to Mr. Henry Shaw's "Specimens of Ancient Furniture." Sir Samuel Meyrick's last important work was 'Lewis Dunn's heraldic visitation of Wales' which he completed in 1846. He had continued a frequent contributor to the Proceedings of the Society of Antiquaries (of which body he was elected a fellow in 1810). Some of his contributions are printed in the "Antiquaries", and others are referred to in the "Gentleman's Magazine," in which work also he wrote many papers from 1823 to 1839 ("Gent. Mag., New Series, vol. xxx., p. 94). Latterly he also contributed to "The Analytical Review" and Quarterly Journal, "The Cambridge Archaeological Journal," &c. Sir Samuel Meyrick died on the 2nd of April, 1846, in his sixty-fifth year. His collection and his domain in Herefordshire, which last he had largely extended by purchase a few months before his death, devolved upon his second cousin Colonel Meyrick.
schools of the Oratory in his native city. Father Respighi, a priest of that congregation, observed the remarkable talents of the boy, and saved him for literature. He was removed to a higher school—one of the so-called 'Scuole Pie' of Bologna—and eventually to the archiepiscopal seminary, where he worked in the classics, letters, metaphysics, law, rhetoric, logic, philosophy, divinity, and canon law in the university, he was admitted to priest's orders in September 1797. Of the details of his progress in the study of languages during these early years no accurate record is preserved; but, it is known that he learned many languages, and wrote a series of letters, essays, and dialogues in childhood, with a very wonderful memory; and that, partly under the various professors in the university, partly by the aid of foreign residents in the city, partly by his own unassisted efforts, he acquired, before the completion of his university career, the Latin, Greek, Hebrew, Arabic, Spanish, French, German, and Swedish languages. In September 1779, at the early age of twenty-two, he was appointed Professor of Arabic in the university, and commenced his labours in the December of that year; but he did not long enjoy what would have been a most congenial office. On the annexation of Bologna, as one of the papal legations, to the newly established Cispalian Republic, he refused to take the oath of the new constitution, and was set aside from the professorship. After the conclusion of the treaty between Pius VII. and the first consol, the ancient constitution of the university was restored. In 1803 Meszofanti was named to the higher professorship of Oriental Languages, and, as he had never been a subscriber to the Universal Library of the public library of the city. The professorship of Oriental Languages, however, being suppressed in 1806, Meszofanti was for some years reduced to great distress, and became dependent for his own maintenance, and that of the orphan family which he supported, on his income derived from private tuition. The elder brother of the late Archdeacon Haro is said to have been one of his pupils, and a living English countess received lessons in English from him at a later period.

Meanwhile Meszofanti steadily followed in private what had become his engrossing pursuit—the study of languages. A letter of his, dated in 1804, to the celebrated Orientalist John Bernard de Rossi, whose personal acquaintance he had frequently formed during a short visit to Madrid in 1806, inclosed a composition in twelve languages, which he submitted for the judgment of his correspondent; and before 1812 his reputation as a linguist had become thoroughly established. The well-known Pietro Giordani, in several of his letters to his friends, calls him "the divine Meszofanti," and declares that his skill in living and dead languages entitles him to be regarded as "a man of all ages and all nations. The war of which Northern Italy was so long the spectacle had enabled him, in the most opportune moment of extending his stock of languages. In the hospital of Bologna, to which he was attached as volunteer chaplain, were to be met—among the invalids of the Austrian, Russian, and French armies—Germans, Hungarians, Bohemians, Wallachians, Muscovites, Persians, Turks. His wish was to offer these sufferers the consolations of religion, partly from his love of the study itself, Meszofanti laboured assiduously to turn these and all similar opportunities to account; and several instances are recorded in which, without the assistance of a grammar or dictionary, he contrived to establish a mode of communication with a stranger who was utterly ignorant of every language except his own, and eventually to master that language sufficiently for all the purposes of intercourse. He thus gained an account of this mode of study during these years, which is not a little curious and interesting. "The hotel-keepers," he says, "were in the habit of notifying to me the arrival of all strangers at Bologna; and I never hesitated, when anything was to be learnt thereby, to call upon these notables in them, to make notes of their communications, and to take lessons in the pronunciation of their several languages. There were a few learned Jesuits too, and several Spaniards, Portuguese, and French, who frequently met me from whom I received valuable assistance, both in their own and in the learned languages. I made it a rule to learn every strange grammar, and to apply myself to every new dictionary that came in my way. I was constantly filling my head with new words. Whenever a stranger of any distinction of rank or of low degree, passed through Bologna, I tried to turn the visit to account, either for the purpose of perfecting my pronunciation, or of learning the familiar words and turns of expression. Nor did all this cost me so much trouble; for, in addition to an excellent memory, God had gifted me with remarkable flexibility of the organs of speech."

In the year 1813 Meszofanti was appointed associate-librarian of the university; in 1814 he was reinstated in his professorship of Arabic, which he retained during this period, especially after the peace, his reputation rapidly extended. Every visitor of Bologna related fresh marvels regarding his prodigious attainments. Tourists from every nation, whether of Europe or of the East, united in representation of his extraordinary knowledge of languages. Among these a particular friend of his was Mr. Stewart Rose, in 1817, reported him as reading twenty languages, and speaking eighteen. Baron Zach, in 1820, sets down the number at thirty-two. Lord Byron, about the same period, speaks of him as knowing eighteen languages, of which he could converse in more or less fluently, and a Brieveurs of parts of speech." When Lady Morgan saw him, in 1829, common report described him as speaking no less than forty languages; but when she inquired from himself the truth of the report, he replied that he had only gone over the outlines of that number. M. Molbech, a Danish traveller of the year 1829, reports the number of his languages at "more than thirty," and testifies to his speaking Danish "with almost entire correctness." French, German, Spanish, Polish, Russian, Greek, and Turkish, were the languages about which he manifested the most impatience. He would only regard to their own, but also to many other languages.

During all these years—except a short visit to Pisa, Leghorn, Florence, and Rome—he had resided altogether at Bologna. In 1823 he transferred his residence to Paris, and in 1824 to Vienna, and in 1826 to Rome. In 1827 he was invited by the pope to settle permanently in Rome, and to accept a prebend in the church of St. Mary Major, which was soon after exchanged for a canonry in St. Peter's; and, on the promotion of the celebrated Angelo Mai, then keeper of the Vatican Library, to the chair of Orientalist of the Propaganda, Meszofanti was appointed to succeed him in the important charge of the Vatican. He held this office till 1835, in which year, conjointly with Mai, he was elevated to the cardinalate.

His residence in a great centre of languages, such as Rome, and especially the facilities of intercourse with the various races represented in the college of the Propaganda, gave a new impulse to Meszofanti's linguistic studies. The reports of his visits at Rome are still more marvellous than those of the Bolognese period. An eminent German scholar, Herr Guido Görrés, who had much intercourse with him in the year 1841, writes thus: "He is familiar with all the European languages; and by this means he has obtained every opportunity of studying the modern ones of the first class, such as the Greek and Latin, or the Italian, French, German, Spanish, Portuguese, and English—his knowledge extends also to the languages of the second class, viz., the Dutch, Danish, and Swedish, which he speaks, besides Hebrew, the Arabic, the Syriac, the Samaritan, the Caides, the Sabic—they, even with the Chinese, which he not only reads, but speaks. Among the Hamitic languages, he knows Goffe, Ethiope, Abyssinian, Amharic, and Asmussi."

What is especially remarkable in the miscellaneous gift possessed by Meszofanti is, that his knowledge of each among this vast variety of languages was almost as perfect as though his attention had been devoted to that language exclusively. The term "perfect," as used in this connection, is derived from what he can do. That the range of language concur in describing him as speaking in each always with the precision, and in most cases with the facility of a native. His pronunciation, his idiom, his vocabulary, were all unexceptionable. Even the familiar phraseology of the day in his mother tongue, and the professional language were at his command; and in each language he was master of all the leading dialects, and even of the provincial peculiarities of idiom, of pronunciation, or of expression.
French, he was equally at home in the pure Parisian of the Faubourg-St.-Germain or in the Provençal of Toulon. He was noted not only for his command of the French tongue, but also for his ability to speak the language of the Black Forest, or to the classic vocabulary of Diderot; and he often amused his English visitors by specimens of the provincialisms of Yorkshire, Lancashire, or Somerset.

The latter of these views, and the quality of his works, which made the name of Mezzofanti almost household words, was well acquainted. He loved to talk with his visitors of the great authors in their respective languages; and his remarks are described as invariably sound and judicious, and exercising careful and various reading, often extending to depictions of women in which his words of admiration were extraordinary. From the poetry of Meli; and an English gentleman was astonished to hear him discuss and criticise Hudibras, of all English writers the least attractive as well as the least intelligible to a foreigner. He was in the habit too of amusing himself by metrical compositions in the various languages which he cultivated, and often wrote for his visitors a couplet or two in their native language as a little momento of their interview. Dr. Wap, the Dutch traveller just referred to, speaks in his Travels of the man as elastic in his powers of adaptation as Mezzofanti replied to a sonnet which Dr. Wap had addressed to him; and the well-known Orientalist, Dr. Thoukuck, having asked Mezzofanti for some memorial of his visit, received from him a Persian couplet after the manner of Hafiz, which contains (although not without some delay) during Dr. Thoukuck's visit.

After his removal to Rome, although he had already passed his fiftieth year, he added largely to his stock of languages. His most notable acquisition during this period was Chinese, which he acquired (partly at the Chinese College at Naples, partly among the Chinese students of the Propaganda) in such perfection as to be able not only to write and converse freely in it, but even to preach to the young Chinese ecclesiastics. During the same period he acquired the American Indian languages, the California, some of the North American Indian languages, and the 'impossible' Basque. And it was in Rome, and especially in the Propaganda, that he displayed in its greatest perfection his singular power of instantaneously posing in conversation from one language to another, without the slightest mixture or confusion, whether of words or of pronunciation.

Mezzofanti, as cardinal, was number of many ecclesiastics received from a Rome, but he never held any office of state. He died on the 15th of March, 1849, and was buried in the church of St. Onofrio, beside the grave of Torquato Tasso.

It is difficult to determine with accuracy the number of languages known to Mezzofanti, and still more to ascertain how many of these he spoke, and with what degree of fluency in each. During his lifetime, as we have seen, report varied considerably at different times; nor was he himself believed to have made any very precise statement on the subject. To a Russian traveller, who visited him before the year 1846, and who begged of him a list of all the languages and dialects in which he was able to express himself, he sent a paper in his own hand containing the name of God in fifty-six languages. The author of a memoir which appeared soon after the cardinal's death in a Roman journal, the 'Civiltà Catolica' (who is now known to be Father Drescian, a Roman Jesuit), states that, in the year 1846, Mezzofanti himself informed him that he was able to express himself in seventy-eight languages. Unfortunately these statements may appear, they seem fully borne out by inquiries (with a view to the preparation of a biography) which have been made since the death of the cardinal. Reports have been received from various parts of the world that many of these languages are still spoken, and that Mezzofanti's works are still studied. Furthermore, it is difficult to institute any direct inquiry; but, judging from analogy, and relying on the well-known modesty and truthfulness of Mezzofanti, we need not hesitate to accept these communications, whatever may be their truth or error. From among his papers now in the possession of his family is a list, drawn up from memoranda contained therein, of no less than a hundred and twenty languages with which he possessed some acquaintance, unaccompanied however by any note specifying the number which he spoke, or the degree of his knowledge of each.

In general learning Mezzofanti's attainments were highly respectable. He was a well-informed theologian and canonist, and an impressive though not eloquent preacher. M. Lebri, the historian of mathematical science in Italy, found him well acquainted with algebra, and reports an interesting conversation which he had with him on the Ciba Ganna (the algebra of the Hindus), as well as on the general subject of mathematics and its history and application. Other travellers describe him as entering freely into the history as well as the literature of their several countries. But as an author he is almost unknown. He occasionally read papers at various literary and scientific societies in Bologna and Rome; but they were the only known publication of a short memoir of his friend and brother professor, Father Emmanuel Aponse, which was printed at Bologna in 1820; and he leaves no monument for posterity beyond the tradition that he was incomparably the greatest linguist the world has ever seen.

**MICA, a Mineral belonging to the extensive series of Silicates of Alumina.** It occurs in oblique rhombic prisms of about 120° and 60°. The crystals usually with the acute edge replaced. The cleavage is very decided, yielding easily thin plates or crystals, and especially in thin foliated masses, plates, or scales; sometimes in radiated groups of aggregated scales or small folia. The colour is from white, through green, yellowish, and brownish shades to black. The lustre is more or less pearly. Transparent or translucent, as in elastic. Hardness 2 to 2 1/2. Specific gravity 2.8 to 3.

The composition of mica is as follows:

<table>

A variety in which the scales are arranged in a plasmous form is called Phanerozo Mica; another in which the plates have a transverse cleavage, has been termed Prismatic Mica.

Mica resembles externally talc, and some forms of gypsum. From talc it differs in affording thinner laminae, and being elastic. It also has not the greasy feel of talc. The same characters except the last distinguish it from gypsum, besides it does not crumble so much on the edge. Mica is one of the constituents of granite, gneiss, and mica-slate, and gives to the latter its laminated structure. It also occurs in granular limestone. It is found abundantly in the United States, in Russia, in Great Britain, and other parts of Europe. It occurs in isolated masses, but filling up the veins and fissures of rocks, into the composition of which it enters. It occurs in the oldest rocks, as well as in these which are new and possess a crystalline character.

In Russia it is used extensively as a substitute for glass, and hence it is called Muscovy Glass. The very thinnest laminae are employed for examining objects under the microscope. Haüy states that these laminae are sometimes not more than the 1-300,000th part of an inch in thickness.

**Lepidolite, or Lithia Mica, occurs in crystals or laminae of a purplish colour, and often in masses consisting of aggregated scales.** It occurs in the Ural. According to Reeve, as quoted by Dana, it consists of the following analysis —

**Fuscisile is a green Mica from the Zilleralp, containing nearly 4 per cent. of oxide of chromium.**

From the description of the species of mica, have been made out of the old species so called. The common Mica has an oblique prism for its primary, but many micas when..."
in perfect crystals have the form of a hexagonal prism. This species has been called hexagonal mica, the dark-coloured micas of Siberia, and the brilliant hexagonal crystals of Vesuvius. There are also hexagonal crystals which have been found by Dövé to have two axes of polarisation, indicating that the three axes of the hexagonal form are not all equal, and that the form is a rhombic prism with the acute edges truncated. This species is called *Rhombic Mica, or Photographit.*

*Margarite,* or *Pearl Mica,* occurs in hexagonal prisms, having the structure of mica, and also in interlocking lizardine. It has the appearance of talc, but differs from that mineral in being a silicate of alumina instead of magnesia. It is found at Siarng in the Tyrol, associated with chlorite.

*Micotmica,* or *schistose talc of Zillerthal,* is a variety of common mica.

*Emerylite* and *Euphylite* are new species, somewhat related to *Margarite.* They are found in Pennsylvania, United States.

*Nacrite* resembles talc, but contains no magnesia. It is whitish and soft, and has a greasy feel.

*Lepidolamite* is a black iron mica, occurring in 6-sided scales or tables aggregated together.

*Omorophite* is an allied mineral occurring in black scales.

*Oderite* is probably a black mica. It can be split into thin leaves. It is opaque, black, and has very little lustre. It occurs in Sweden.

MICKIEWICZ, ADAM, the greatest poet that Poland has ever known, was born in the year 1798 at Nowogrodzie, a small town in Lithuania, one of the few in the environs of which the ancient Lithuanian language is still spoken. It is certainly remarkable that a man, the chief effort of whose life was to contribute to the unity of nationality, and the regeneration of Poland from being overpowered by those of Russia, should be the native of a country which had lost its language, its nationality, and its religion by its union with Poland. His father, by birth a noble, was by profession an advocate, and an unsuccessful one, and his end was a legal writer of some reputation. Mickiewicz himself had so little respect for the nobility of his family, that in his poem of *Pan Tadeusz,* in which the scene is laid in Lithuania, published in 1831, he introduces his family name as that of a disreputable and belligerent nobleman in a pastoral. It is singular that Pushkin, who acquired the name of the Russian Byron as Mickiewicz did that of the Polish Byron, takes occasion in his play of *Boris Godunov,* to introduce one of his own ancestors in an odious and contemptible light. The feeling of the two poets in this respect was very different from that of their English prototypes.

Mickiewicz after receiving his preliminary education at Nowogrodzie and the grammar-school of Minsk, was sent when a boy of seven to the University of Wroclaw, where his uncle, an ex-Jesuit, was one of the professors. The university under the auspices of Snidecki the mathematician, and the patronage of Prince Cartoryski, then Minister of Public Instruction, at the time of its liberation, the chief seat of learning for eleven millions of the population of Poland, and celebrated for the success with which the exact and natural sciences were taught. Almost the first person whom Mickiewicz saw at Wilna was Thomas Zan, a celebrated Polish patriot, who was occupied with getting up secret societies among the students, of which Mickiewicz at once became a member. The professor of history, Lelewel, was another determined opponent of government, and to him Mickiewicz addressed the first poem he published. While at Wilna he fell deeply in love with the sister of a fellow student, Maria Wereszewskowa, by whose addresses were finally rejected for those of a richer suitor. When he left the university, where he had first been noted for his devotion to chemistry and afterwards to poetry, he was appointed professor of classical literature in a college at Kowno, and it was while residing there in 1822 that two small volumes of poems from his pen were published at Wilna. Like those of Burns and Byron, they were at once read and admired. 'Grzazyna,' in which the poet takes for his scene the old castle of Nowogrodzie, the ruins of which are still remaining near his native town, he tells in a tersely classical and sculpturaque style, which reminds the reader of the happiest effusions of Tennyson, the story of a Lithuanian heroine, who, in consequence of the wanton rage of her lover, meets death on the field of battle. It became the favourite poem of a real Lithuanian heroine, Emilia Plater, who eight years afterwards fought in the Polish ranks in the insurrection of 1830. The 'Dziady,' or 'Ancestors,' is a poem of a new kind, an autobiographical drama, in which the poet appears as one of his own characters. In it he relates, with this slight veil, the story of his love for Maria, the 'Mary Chawor,' or 'Mary of the Lilies,' whose memory Mickiewicz does not forget. The 'Dziady,' published after long years of interval—"To the sacred memory of John Sobolewski, of Cyprian Dziskiewicz, of Felix Kolakowski, my fellow-students, my friends, and my countrymen, and to the memory of Marias Zdanowicz, my fellow-country, who, with a longing for that country in their hearts, died at Archangel, at Moscow, at St. Petersburg, the martyrs of their country's cause." Imprisoned for upwards of a year in the Basilian convent at Wilna, while the examination into the conspiracies and insurrections against the Russian government, Ruizylev and Bestebun, afterwards so active in the abortive insurrection at the accession of the Emperor Nicolas, were ardent for the Polish cause. In a poem "to his Russian friends," written in after years, Mickiewicz speaks of the indignation with which he regarded the venality of the Tsar, and alludes apparently to Pushkin, to whom they introduced him, as having deserted the cause of liberty. The 'Russian Byron' and the 'Polish Byron' met at St. Petersburg, and the idea of a division of labour evidently struck them, and the poet of *Grzazyna* seems to have been so easily accessible to them. The division of labour was not looked upon with favorables eyes by the Russian government, which ordered Mickiewicz to Odessa; there, however, he soon obtained permission for a tour in the Crimea, which gave rise to a series of 'Crimean Sonnets,' the first sonnets in the Polish language. That subject now gives them an additional interest. One of them is 'On the View of the Mountains from Kozlov,' or 'Eptoria; another, 'On the ruined Castle of Balaklava.' These poems have been very popular; and one of them, 'The Peasant Boy of Rumania,' the inhabitants of which are of which were afterwards delineated with all the force of his genius, Mickiewicz, found guilty of being a member of two secret societies, was condemned, in 1824, to perpetual banishment in the interior of Russia. At the age of twenty-six Mickiewicz left Poland for exile, and he never saw it again.

At St. Petersburg, where he was at first permitted to reside, Mickiewicz found himself, in the latter years of the Emperor Alexander, in the midst of active opposition against the Russian government. Ruizylev and Bestebun, afterwards so active in the abortive insurrection at the accession of the Emperor Nicolas, were ardent for the Polish cause. In a poem "to his Russian friends," written in after years, Mickiewicz speaks of the indignation with which he regarded the venality of the Tsar, and alludes apparently to Pushkin, to whom they introduced him, as having deserted the cause of liberty. The 'Russian Byron' and the 'Polish Byron' met at St. Petersburg, and the idea of a division of labour evidently struck them, and the poet of *Grzazyna* seems to have been so easily accessible to them. The division of labour was not looked upon with favorable eyes by the Russian government, which ordered Mickiewicz to Odessa; there, however, he soon obtained permission for a tour in the Crimea, which gave rise to a series of 'Crimean Sonnets,' the first sonnets in the Polish language. That subject now gives them an additional interest. One of them is 'On the View of the Mountains from Kozlov,' or 'Eptoria; another, 'On the ruined Castle of Balaklava.' These poems have been very popular; and one of them, 'The Peasant Boy of Rumania,' the inhabitants of which are of
every Russian. Two Russian translations were published, and it is even said that the Emperor Nicholas sent a message of praise to the poet. The enthusiastic support of the Russian service was also, it is said, proffered to him; but the only favour he asked was to be allowed to visit Italy for the benefit of his health, and he obtained it by the intercession of the Russian poet Zhukovsky. He left Russia, as he himself said, in 'absentia' and for his health, and arrived in Paris in 1825.

After passing through Germany, where he spent some days with Goethe, he resided at Rome, where he became intimate with James Fenimore Cooper. It was at Rome that the news of the Polish insurrection of 1830 reached him, an insurrection which was crowned with success only after the suppression of the Polish nation at Warsaw. The news reached him with the Ode to Youth. The rising was crushed by the time Mickiewicz had reached Posen on his way to join it. He retired to Dresden, and then returned to Paris through the part of the 'Dzidzi', which was first published in 1832 at Paris.

As in the former part of this poem Mickiewicz had told in a dramatic form the tale of his early love, in this he related in a succession of scenes the story of his imprisonment in Wilna before the sentence of banishment. As a lover, he represents himself as having been driven by disappointment to insanity; as a man, he actually delineated himself as possessed by the devil, and the devil as exorcised out of his being. As a priest, he is the representative of a peaceful spirit, but even a heavenly, the importance of which is represented as having called down the chastisement. This strange and repulsively scene is accompanied by others of a less eccentric character, in which the poet's friends and foes are represented in a most unflattering light. The horrors of the Russian army in Poland are depicted with surprising power and pathos. On the whole, this wild production is one of the most remarkable for poetical power that the literature of the quarter of a century since 1830 has produced.

The last great poet of Mickiewicz, 'Pan Tadeusz,' or 'Sir Thaddeus,' was published in Paris in 1834. It differs as entirely in style and sentiment from the 'Dzidzi' as 't' reason for the Lithuanian domestic life in the year 1812, the time of the poet's boyhood, in which the somewhat insignificant story of a common-place hero is relieved against the dark background of the approach of Napoleon's invading army on its march to Russia, and the intense excitement it produces amongst the Lithuanians, from the peasant and the publican to the priest and the noble. By some it is regarded as totally unworthy of the powers of Mickiewicz—by many as the finest production of his genius; and there can be no doubt that it is by far the most pleasing and the least objectionable.

Up to this period the career of Mickiewicz had been one to which his Polish admirers had looked with constantly increasing hope. His first work was published in the literature of his country without a rival either in the present or the past. "He is our Byron, our Shakspere," was the verdict of Klementyna Hoffmanowa herself, a staid and decorous writer. None indeed could then have foreseen in what darkness the star of Mickiewicz was to set. In 1839, two years before the appearance of 'Pan Tadeusz,' he had published 'A Book of the Polish Nation and the Polish Pilgrimage,' which presented an unbroken series of dull absurdity and extravagance. It was probably the influence of his name which procured its translation into French by Count Montalembert, and into English by Lach Szyma, combined with the fact that it in Mickiewicz presented himself to the world in the character of a fervent Roman Catholic, convinced that it was to its toleration of Protestantism that the ruin of Poland was to be ascribed.

Before this period Mickiewicz had fixed his residence at Paris, and it was in that city, in 1834, that he became united to Celina Szyma, a Polish lady, to whom he had, in 1829, promised to return. In 1838 he returned to Poland, but to the French he was strongly attached, but his pecuniary circumstances compelled him to accept, in 1839, an appointment as professor of classical literature at Lazanne. In the character of a literary and historical historian, determined to establish a chair of Slavonic literature and the Slavonic languages at the College of France, it was considered a good fortune for the minister to be able to appoint, for the first professor, the greatest poet of Poland. The first lectures which he gave were eagerly attended, and were reproduced in the French and German journals; but ere long strange alterations began to develop themselves.

Brandon, in 1841, when Madame Mickiewicz, who was in bad health, had received some benefit from being mesmerised by a Polish fanatic named Towsianki, Mickiewicz had allowed himself to become associated with this man as the interpreter of certain dreams, in which Towsianki alleged that he was favoured with particular revelations on Slavic literature and the Slavonic language. Mickiewicz, who was represented as the new Messiah of a new religion, of which the principal feature was the worship of 'Giesza,' the word for 'Virgin Mary,' was represented as a new and necessary development of improved Christianity. At last, in 1844, the French government interposed, ordered Towsianki to quit Paris, and put a stop to this course of proceedings. Towsianki and his wife were tried and acquitted, and Mickiewicz's name appeared in the list of professors for some years afterwards, but he lived in obscurity, an object rather of compassion than other feelings. In 1848 the revolution of February again excited his hopes for Poland, and he made a journey for that purpose of gaining over the pope, and was received with enthusiasm by the insolent at Florence. In 1851 his name appeared in the French calendars as 'Sub-Librarian of the Library of the Arsenal at Paris;' for which he was appointed by the president, who expressed the hope that this venial error the incalculable of the holiness of Napoleon I.

About 1854 Mickiewicz became a widower, and he afterwards returned in some degree to public life. Soon after the revolution in France he was appointed by the government commissioners, in connection with the French emperor, to remind him of the opportunity that presented itself for redressing the wrongs of Poland, and in 1856 he was sent by him on a secret mission to the East, which was destined to prove the last incident in his career. He died at Constantinople on April 26, 1855. His remains were removed to France, where they were interred in the cemetery of Montmartre, and a subscription was opened directly after at Paris and London for the benefit of his widow.

One of the most remarkable editions of Mickiewicz's works was published at Paris in 1829 and 1829, in three volumes, at the expense of the Countess Ostrowska, a Lithuanian lady, who presented the money received from its sale to the author, then a captive in Russia. It is generally stated to be the first book printed in French in the Polish language, but it had two predecessors, as its editor, Leonard Chodzko, points out in the preface—one in 1829 and another in 1814. Its successors may be counted by hundreds, many of which have been published in London, as well as at Paris and Berlin. The best edition of Mickiewicz's works is that in four volumes, issued at that city in 1844, revised by the poet himself, and edited by Alexander Chodzko. A translation of all his works into English was published at Oxford, and another at London in 1847; and in 1844, he was published at Paris in 1841, and again in 1844, with two very different prefaces, the first all enthusiasm for Mickiewicz and his genius, the second full of the disappointment and estrangement his devotion to Towsianki had inspired. The English language possesses one only of his larger poems in two translations—the 'Wallenrod,' in prose by Leon Jablonski, Edinburgh, 1841, and in verse by Catley, London, 1842. An article of some length on Mickiewicz appeared in the London 'Metropolitan,' at the outset of his career, and another in the 'Athenaeum' for 1856, on the occasion of his death.

The name of the 'Polish Byron,' which has been generally assigned to Mickiewicz, conveys as correct a notion of his character and the extent of his genius as any single epithet could possibly do. The most striking point of dissimilarity between the two is the vehement patriotism of the Pole, and the indifference to his country which was professed by the Englishman, but a great deal of this was probably owing to the different revolutions by the Virgin Mary. In his lectures of a foreign sovereign, and the other in the most prosperous period of his history. It may be remarked that in 'Pan Tadeusz,' where Mickiewicz has occasion to delineate the character of a gallant Polish knight, the poet seems, perhaps on his own part, as arrogant, ignorant, prejudiced, spiteful, and hesderong, with scarcely any good qualities to balance. There is an obtrusiveness in Mickiewicz's own moral perceptions which it is often painful to observe. His poem of 'Wallenrod' is devoted, from the first line to the last, to the incalculable of a spirit of systematic treachery, and in one
In microscopic observations two things must be remembered: that in the microscope, especially with high powers, we see surfaces, not bodies. It frequently happens that in looking upon surfaces, we get a glance into the depths of transparent objects by changing the adjustment, without altering the position of the object; it more often happens that upon examining a surface we find it impossible to make them out to be bodies until we have changed their position, and ascertained their dimensions in three different directions; this, in many cases, from the nature of the object, is a matter of great difficulty. Such that we seldom see the objects under the microscope in their natural condition; that we consequently must take into consideration the changes which we ourselves partly produce, either by the medium in which the object is placed, or by the use of the knives of the opticians. Long and thorough practice with the microscope secures the observer from deceptions which arise, from any fault in the instrument, but from a want of acquaintance with the microscope, and from a forgetfulness of the wide differences between the eye through a microscope. Deceptions also arise from a neglect to distinguish between the natural appearances of the object under observation, and that which it assumes under the microscope.

To obviate these difficulties must be added those originating in the eye itself, through the so-called ‘Mouche volantes,’ and those also which arise from the observer being unacquainted with the appearance, under the microscope, of the common things which are dispersed throughout the air and water, such as air-bubbles, mud, and other material. These are also caused by air-bubbles, by molecular motion, and by the currents which arise upon the stage of the microscope from the evaporation of water, or from the intermingling of two fluids. The observer must learn to know these, and to know when they are the cause of the errors, and then no further deceptions can arise from these causes.

The proper use of the microscope is always the principal thing to be considered. Hedwig, with the microscope of his time, examined a few objects, the greater extent than many observers with incomparably better instruments have done.

In order to use the microscope properly, the observer must be skilful in handling the instrument and the objects, and above all things, his mode of proceeding must be conducted with accuracy and judgment, and he must be able to give a sufficient reason for every thing that he does. His progress in research will be slow, but sure; he must endeavour to obtain objects from every possible source, and must examine them thoroughly; he must verify his own observations as scrupulously as possible, and so, progressing step by step, he will attain the desired end. Work without method will seldom lead to any result; the finest sections of wood made only in a hasty way, and in the wrong direction, do not lead to any knowledge of the wood under observation. Single observations (of wood, for instance), irregularly made from time to time, only show the condition of the wood at the time of that particular observation, and throw no light on its condition at an earlier or later period; whilst sections taken in a proper manner, and well-preserved specimens of the successive conditions of the wood, furnish irrefragable proofs, the one of the construction, and the other of the development in the growth of the wood under observation. (Schacht ‘On the Microscope.’)

Before speaking of the methods of examining and preserving bodies for microscopic observation, it will be better to draw attention to the natural objects, to the examination of which we have arrived by means of the microscope. The inorganic and organic worlds the microscope is made subservient to observation. To speak first of inorganic substances and materials not under the influence of vital action—it has been already described how by means of the forms of minute crystals. In this way it aids the analytical chemist. In the examination of the saline contents of water, if a small quantity of the water is allowed to evaporate upon an ordinary glass slide, its contents may be judged of by the forms of the crystals obtained from organic bodies this plan of examination has been recently applied with the most interesting results. A series of the most beautiful illustrations of the microscopic characters exhibited by crystal objects, by the means of which the crystals, 'will be found in Dr. Otto Funke's 'Atlas of Physiological Chemistry,' and also in the 'Micrographic Dictionary,' by Dr. Griffiths and Mr. Henfrey.
Not only are the natural crystaline constituents dissolved up in liquids thus obtained, but new combinations obtained by the addition of re-agents. This mode of inquiry is equally applicable to the microscopic anatomy of the body, and the importance of the results is rapidly becoming one of the most important means of diagnosis in the hands of the physician.

Although dealing with the disposition of large masses of matter, the microscope, in the hands of an experienced operator, is replete with the most interesting and important results. The knowledge is obtained by the geologist by examining minute portions of them with the aid of the microscope. It is by this aid of this instrument alone that the question of the manner in which an extensive series of rocks has been deposited, and the manner in which they are superimposed on each other, can be decided. In all these cases, the microscopic examination is applied to the determination of the nature of the material, and its structure, and is as much applicable to the study of the origin and geographical distribution of rocks, as to the study of the geographical distribution of plants and animals. In this manner, the microscope has been a source of increasing interest to microscopic observers.

The earliest observations on the minute being were made by Leucow, a Dutchman, who discovered them in the 16th century. In the year 1665, it was left for Ehrengard, during the present century, to make known to it full extent the immense variety of forms assumed by these microscopic beings. [DIATOMACEAE: S. 2; MOLLUSCA: S. 2; ECHINODERMA: S. 2; and STAR FISH: S. 2.] Since the publication of the last-named work, the curious and interesting objects presented to the microscope have been the subject of research by many observers, and have been studied with increasing success. The objects of microscopic investigation are now divided into two classes: those which are visible to the naked eye, and those which are only visible with the aid of the microscope.

The cells of the animal and vegetable kingdom are the most important objects of microscopic investigation. They are the fundamental units of the plant and animal world, and their study is of the greatest importance to the student of biology. The cell is the smallest unit of life, and its structure and function are of the utmost importance. The study of the cell is of great importance to the student of medicine, for it is in the cell that the fundamental processes of life are carried on. The cell is the unit of growth, and it is in the cell that the genetic material is stored. The cell is the unit of reproduction, and it is in the cell that the process of sexual reproduction is carried on.

The microscope is the most important tool in the study of the cell. It is by the microscope that the structure of the cell is studied, and its function is determined. The microscope is the tool by which the student of biology can learn the secrets of life, and it is the microscope that has made the study of the cell possible. The microscope is the tool by which the student of biology can learn the secrets of life, and it is the microscope that has made the study of the cell possible.

with such an illumination; for exact, observation, therefore, the daytime only must be selected. In order to interrupt the light of the horn substance, the means of the light, and the light is thrown upon the beam downwards, the microscope is placed at least three feet from the window, the microscope is turned with the mirror towards the light, and the whole instrument, but especially the mirror, is placed in different directions. When the eye-glass looks through the microscope, the light is, in fact, sought after; when the field of view appears clearest and brightest, the object which is to be observed is pressed to the microscope.

When it is wished to examine opaque objects with intense light, the microscope may be advantageously brought to the window. Since for this kind of illumination a much larger quantity of light is necessary, direct sunlight is sometimes desirable; in the absence of this, the condensing power, which is produced by means of the greatest possible quantity of light is concentrated upon the object. In this kind of illumination, the access of light from below, which would interfere with the observation, is prevented by closing the diaphragm. For objects which are altogether opaque, a background which is white, but not glittering, is often advantageous.

The table at which microscopical observations are undertaken must be sufficiently large, and very firm; it must be so arranged that all the apparatus which is ever wanted shall be within reach. There is no more pleasing than the speed at which a microscope can be used in microscopical investigations when time passes only too quickly; moreover, in a very confined space, it is impossible to make effective preparations with the simple microscope. Every observer who has observed in a microscope, will remember the first instance with a low magnifying power, since by that means a larger portion of the object is seen, and thus a better impression with the whole is obtained. Should the light be too strong, the plane mirror may be used instead of the concave one. When the observer has gained as much information as he can with the low-magnifying power, for instance, one of 50 diameters, or, in some cases, even a less magnifying power, the object-glass is changed for a more powerful one. When the most powerful object-glass has been used, and a still stronger magnifying power is found desirable, then a stronger eye-glass is taken. As a general rule, the eye-glass of lowest power should be used, and, if necessary, the magnifying power should be increased by passing from the object-glasses of lower power to those of higher power; but, nevertheless, for seeing with convenience, and especially for drawing, the use of a powerful eye-glass is often not without advantage. As long as the magnifying power can be increased by means of an object-glass, recourse should never be had to the eye-glass, since both the light and the sharpness of outline of the image are necessarily diminished by the use of a powerful eye-glass, which is not the case in using a more powerful object-glass.

When the object is thin enough to be seen with transmitted light, it is first illuminated with light transmitted directly, and is examined with gradually increasing, magnifying powers; should any details of the image remain undefined, obliquely transmitted light is used, which is inaudited into all the different corners of the object. In some microscopes this is attained by turning the stage round its axis; where this arrangement is not wanted, the position of the object must be changed by moving it with the hand. Lines always stand out most clearly when oblique light falls upon them at a right angle: where, therefore, a line is suspected to exist, or is not clearly defined, particular attention must be paid to this circumstance. In many objects, the light of the same general rule generally holds good, and particular care must be taken, by turning either the stage or the object itself, to concentrate the light in all possible directions upon the object. Objects-glasses of very high power cannot be used with incident light, inasmuch as the shortness of their focal length prevents the light from falling upon the object; in this case recourse must be had to less powerful object-glasses, and more powerful eye-glasses.

As a general rule, low-magnifying powers are sufficient when incident light is employed. As incident light is employed, it consists of Iceland spar, one of which is fitted beneath the stage, the other is attached to the eye-piece. Tourmaline is also used for the same purpose. Large crystals of iodine of quinine have also been shown by Dr. Herapath to be applicable in polarising light for the microscope. (Quarterly Journal of Microscopical Science.) 1000 powers of the object-glasses frequently exhibit their structure in a more perfect manner. Various objects, especially crystals of a spherical or oval form, exhibit a beautiful variety of colour in this way. In some cases it may be made the means of testing the nature of an object.

In most instances, objects are examined under water: it is but seldom, as, for instance, in examining pollen or spores, that it is necessary to observe them in different media, and in order to do so the object-glass is changed for a case of the object-glass which operates injuriously, especially when the object is not quite covered by it: it is therefore advisable, for certain particular objects, as, for instance, the embryos of grasses, to observe them with a glass which is free from water, by placing the fluid in a cover, and adding water with a camel's-hair brush, the object is generally sufficiently and fully immersed. When low-magnifying powers are used, it is not necessary that the object should be placed under a glass cover, in fact, in many cases where it is wished to have the power of turning the object round, or when it is thought that the object may be improved by any additional cutting or preparation, it is very advantageous not to cover it; when object-glasses of very high power are used, the time is saved by not using a cover, as the less the object, the less is the effect of the fluid upon the object plate, it is necessary to make use of glass covers. When these are used, the fluid in which the object lies freely becomes less powerful, to the extent of about one-third, and in the case a fresh drop is added at the edge of the glass cover by means of a glass rod, or a clean camel's-hair brush, which may be used when it is wished to add a solution of iodine, or of chloride of zinc and iodine, to objects which are already immersed and waxed.

When any chemical re-agents are used, whether iodine, caustic potash, or an acid, the object should always be covered with a thin plate of glass; in using volatile acids, such as nitric acid and hydrochloric acid, too much care cannot be taken. The vapour of sulphuretted hydrogen has a very injurious effect upon flint glass, which is used by some opticians for the under side of the object-glass.

When the microscope is in daily use, it is a good plan to keep it under a high bell-glass, or an ornamental shade. The greatest cleanliness and accuracy are indispensable for microscopical investigations: it must be laid down as a rule always to use the cleanest water, in the cleanest vessels, for moistening the slides. Even with this precaution it is impossible to prevent the object-glasses from becoming coated with particles of dust. Excessive things of this kind will not easily deceive a practised observer; a beginner however may be easily misled by them. Water which has been left standing will contain much dust, which is liable to obtain the inferior sorts of animals and plants; and when different objects are examined one after another, fresh water should be taken for every new object, in order that no particles of the objects which have been previously examined may be mixed with the water upon the slide. Mucilages may be traced to a neglect of small precautions of this sort.

In order to be able to recognise extraneous objects as such, it is advisable to gain an acquaintance with those things which, notwithstanding all precautions, cannot always be avoided. To this class of things belong: 1st, Air-bubbles, which, with transmitted light, generally appear in the form of circles of larger or smaller diameter, with a dark, black-looking rim: with incident light, on the contrary, their rim is white; 2nd, Dust, which appear as a dark spot on the cover and in contact with it, the large air-bubbles frequently assume a very irregular shape; the above-mentioned optical fact is generally however by far the best proof of the presence of air, and by its aid accurately detected both in and between the cells of plants. 3rd, Colourless or coloured fibres of paper, or of linen, woolen, or silk-textures, left behind upon the object-glasses, from the cloths with which they have been cleaned, and also the hairs which have been made fast with the brush, and also dust of irregular shape, which are frequently coloured, and are probably produced by the decay of organised bodies. If it is wished to examine plants, or parts of plants, which grow in water, it is necessary to pass them through a spirit for a short time, and this spirit must be paid to the many organised bodies which are likely to be met with: pains must be taken by careful observation to become acquainted with the lower forms of animals and
plants: it is necessary, for instance, to be able to distinguish the common forms of *Infusoria*, both those that are provoking and those that are not, which is particularly important in connection with the yeast plant, the different forms of mould, the *Oscillatoria*, and such like things, in order to be able to separate them from the particular object under consideration.

The epithelial cells of the mucous membrane of the mouth are another object which can be examined in this way. When the brush is drawn through the mouth previously to bringing an object upon the object-plate. It is advisable never to pass the brush through the mouth. When in cutting the objects, the latter should be softened by heating the brush and forefinger, or upon the forefinger alone, it often happens that small fragments of the skin of the finger are cut off at the same time. The observer must learn to distinguish these fragments, as well as the small pieces of cork which he will make by cutting the object, from the real object.

Appearances of motion, either usual or accidental, may also give rise to mistakes, and these must therefore be learned. Molecular motion is peculiar to all very small bodies, contained in a thin liquid medium; it consists in a trembling motion of some of these small bodies; it is often seen in the interior of pollen grains; it can be observed still better in certain fluids, for instance milk, when a small quantity is mixed with water, and placed under the microscope. The milk becomes opalescent from time to time due to the phenomenon of molecular motion.

When acquaintance is once made with this phenomenon no further deception can be caused by it. The same effect follows from accidental currents upon the object-plate, which may take place either by evaporation or by the mingling of two fluids of different gravity, or by the dissolving of any salt existing in the fluid.

Observations are made less frequently with reflected than with transmitted light, but since the latter can only be used for very thick objects, the principal point to be gained in dealing with opaque objects, is to make such an arrangement of them, as to enable the observer clearly to make out their details. The manner in which the object is divided must be regulated and altered according to the nature of the object as well as the powers of the microscope. One is often helped by the microscope, to obtain respecting it. Firm homogeneous textures, such as wood, must be treated quite differently from delicate objects composed of different organs, such as buds and blossoms, in the case of wood it is sufficient to take as thin a slice as possible, cut in a certain fixed direction; in the case of buds and blossoms, attention must be paid not only to the direction, but also, particularly, to the point at which the section is made; it is necessary to examine the organ at several points, the stem, the leaves, the whole of the bud or blossom, and an equally accurate transverse section made at different heights, in order to ascertain the arrangement of the organs with respect to one another; moreover, the different parts of the organ should be separated and examined as separate elements; in cutting, and especially in inquiries connected with the development of plants, a dissecting microscope is necessary. The same remarks apply to hard and soft animal tissues.

Succulent or spongy tissues have generally large cells; it is not necessary therefore to have thin sections of such tissues, which are always difficult to make. Delicate animal tissues may advantageously be placed in spirit or pyrogene acid for some days, provided it is not necessary that the tissues should be examined whilst fresh; but there is little advantage to be derived from treating botanical objects in that manner. It is a good plan however, in many cases, to saturate delicate portions of animals and vegetables with thick gum spirit, which will prevent them being dissolved.

In dissecting, different methods must be adopted, according to the magnitude of the different objects; objects of large size may be held with the left hand, or with the thumb and forefinger of that hand; very small or thin objects, such as the stems of mosses, thin twigs and roots, leaves, small seeds, and such-like things, may be placed between two pieces of cork, and thin slices of the object cut by means of a sharp knife or razor.

The atmosphere is sometimes disagreeably impeded by the presence of air, which becomes accumulated in the hollow parts of the petals, in the intercellular canals, in the vessels; and in wood; it is best removed by placing the object for a few minutes in a small watch-glass filled with alcohol; when taken out of alcohol the object is transferred to the slide. When it is wished to examine the cell contents, in which the changes are generally produced by the operation of alcohol, the removal of the air may be advantageously effected by the use of the compressorium, which is provided for the purpose, whilst the observer looks into the microscope. In the absence of a compressorium, the fingers may be lightly pressed against the glass cover.

For transferring objects from one fluid into another a very fine capillary tube should be employed; needles and other sharp instruments should never be used for this purpose, since the object may be easily injured by them. When the object is very small it will be more easily found if the watch-glass is darkened up, and the object will then be visible with a much higher magnifying power. The microscope only affords a view of one surface of an object; when, therefore, bodies are subjected to examination, it is not sufficient for a correct understanding of them to examine one side only; a transverse section and a longitudinal section are necessary. The two sections in different determinate directions, must be carefully examined and compared with one another before the observer can be satisfied that he has made out the construction of the body under observation. That which in objects of large size is attained by the help of the knife, in objects of small size, in the case of very small opaque objects, by examining them on different sides. In examining small bodies which are very transparent, as, for instance, the ovules of Orchis, or grains of starch or pollen or eggs of insects, it is necessary to look at them from time to time, by which means the upper side of the object is first brought into the focus, then the middle (which may be called an optical section, transverse or longitudinal, as the case may be), and, lastly, the under-side. The more perfect the microscope, the more the observer should be careful. The more sensitive is the instrument to any small alteration of the focus, on which account the observer should always keep his hand upon the fine-adjusted screw whilst he is employed upon observations requiring much accuracy. The sensibilities above mentioned increases, in good instruments, in proportion to the magnifying power, and also with the angle of the aperture of the glass.

The accurate adjustment of an object is judged of by the sharpness of the lines seen upon objects, or by the fineness and clearness of the outline, which should be soft, but well-defined. The scales of the *Hippocastanum* leaf, a common brown butterfly, are well adapted for enabling a person to judge of the accuracy of an adjustment; the smallest change of focus causes transverse strike to disappear.

In examining small round bodies, such as pollen-grains, the position of the object should be changed by pushing the glass-cover so as to cause the bodies to roll about; by this means different sides of the objects are seen, and from the different images presented to the eye their true form is made out.

Small objects should never be compressed between two glass slides, that being too rough a method of proceeding. If however it is supposed that anything is to be gained by compression, then it is advisable to use the compressorium, which is an instrument consisting of a mechanical arrangement by which the thin glass covering an object may be compressed at will. When the compressorium is cautiously used, the observer, by carefully watching what takes place, can gain a knowledge of the changes produced by pressure during the time the compressorium is permitted to work. In certain cases, where, for instance, the question is whether a particular object is a delicate cell or a drop of some fluid, the compressorium may be of service; since, if a cellular membrane be present, it will be compressed and displaced, whereas if the pressure is increased, whereas the drop, whether it be oil, liquid resin, or any other chemical substance upon the slide, will only change its form.

In examining any object, whether animal or vegetable, it is not sufficient to observe the nature, form, and arrangement of the cells; it is necessary also to pay attention to their contents, which, in the case of plants, are different according to the functions assigned to them by nature. It is necessary then to ask, What are its contents? We therefore, to what extent is it filled? Whether its contents are fluid with a solid substance contained in the fluid. Another question which arises is as to the nature of the fluid contained in the cells. It may be a homogeneous fluid, or of fluids of different consistencies, apparently not intermingling with one another; the manner in which 3 F
these fluids are affected by chemical re-agents has also to be considered. Lastly, the solid ingredients of the cell-contents, and their physical and chemical nature, must also be attended to.

There are some substances dissolved in the juices of the cell, such as sugar, for example, for which no certain chemical is given. Gum and dextrin, for instance, contain an intense yellow colour, almost brown, is produced. When the presence of oil or resin is suspected, the object should be placed in ether or pure alcohol for some hours, which will dissolve both oil and resin, and allow the inspection of the cell contents. Some re-agent must be used which operates upon the salt. Starch is detected by being coloured blue by iodine.

The following is a list of re-agents which it will be found convenient to have at hand in the examination of either animal or vegetable substances—

1. Alcohol, which is used principally for removing air from sections of wood and other preparations, and as a means of dissolving certain colouring matters, &c. It coagulates the albumen of animals.

2. Ether, which is principally used for dissolving resins, fatty essential matters, and other oils, &c. This is also useful for removing air.

3. A solution of caustic potash, which is used for the preparation of sections, is also useful in certain cases from its effects upon the contents of cells, and upon the thickening layers. It dissolves up substances of an albuminous nature. This solution often works better after warming.

4. A solution of iodine (one grain of iodine, three grains of gum or starch, one ounce of distilled water), for colouring the cell-membrane, and the contents of the cell.

5. Concentrated sulphuric acid. This is principally used for examining pollen and spores. In the examination of hairs it renders the cells very distinct.

6. Diluted sulphuric acid (three parts of sulphuric acid and one part water), for colouring the cells of plants which have been previously moistened with the solution of iodine. The object is moistened with the solution of iodine, which is then removed with a fine camel's hair brush, and by means of a glass rod a drop of sulphuric acid is added, and the object is then immediately covered with a covering-glass. The effect of the sulphuric acid and iodine, as well as that of the iodised solution of chloride of zinc, is not always the same over the whole surface of an object. At the points where the mixture is more concentrated, the colouring is more intense; frequently places remain without any colour. The colour changes after some time; in twenty-four hours the object is in red.

The iodised solution of chloride of zinc produces generally the same blue colour in cellulose as iodine and sulphuric acid: the former is preferable in many cases, inasmuch as its effect is not so rapid, and it is not injurious to the cells. Both re-agents are well known, and may be employed in their proper place, as compared with one another. Besides maceration, it is advisable, in examining woods, to adopt the plan of boiling this section for about a minute with a solution of caustic potash; after this boiling, the wood-cells, which were not previously turned blue by iodine and sulphuric acid, become a violet or blue colour upon the application of the iodised solution of chloride of zinc.

7. A solution of chloride of zinc, iodine, and iodide of potassium. This solution is boiled into an alkali until it is placed in a little water, produces the same colour as iodine and sulphuric acid. This solution was first recommended by Professor Schultze, of Rostock; it is more convenient to use than iodine and sulphuric acid, and produces almost the same results; it is, moreover, not so destructive as sulphuric acid.

The exact prescription for this solution is as follows:—Zinc is dissolved in hydrochloric acid; the solution is permitted to evaporate, under contact with metallic zinc, until it attains the appearance of vinegar; and the syrup is then saturated with iodide of potassium. The mixture is then boiled until it is perfect, and the solution, when it is necessary, is diluted with water.

8. Nitric acid, or, what is better, chloride of potash and sodium carbonate. This is used for separating cells. The method of maceration described in microscopic practice, and which is much to be recommended, is as follows:—The object (wood, for instance), is reduced in size to the thickness of a lucifer-match; it is then thrown into a long and tolerably-wide boiling-tube; to this is added, in a little while, an equal volume of chlorate of potash, and as much nitric acid as is at least sufficient to cover the wood and the potash; the tube is then warmed over a spirit-lamp; a brisk development of gas quickly appears; the boiling-tube is withdrawn from the flame, the oxidising mixture is employed to work for about a minute and a half or three minutes, and the whole is thrown into a saccar with water; the small pieces which adhere slightly to one another are then collected, placed in the boiling-tube, and boiled repeatedly with alcohol, until the latter appears perfectly clear; the last they are then boiled out more, for the last time, with water. By the help of the simple microscope the cells are now separated from one another with a needle, and selected. The boiling with nitric acid is always beneficial. The next step is the preservation of the room where the microscope is kept, because its glass might be injured by the evaporation which is developed. Thin sections of plants, for instance, of woods or leaves, are warmed for half a minute, or a minute, in a watch-glass; the boiling is unnecessary in this case; the section is taken out with a little rod, and thrown into a small watch-glass with water. Nitric acid is one of the best agents for removing animal or vegetable tissues from silica, as in the case of the Devonian rocks.

9. Oil of lemons, or any other essential oil, for examining pollen and spores.

10. A tolerably strong solution of muriate of lime (one part of dry muriate of lime, and three parts of distilled water) is useful for preparing microscopic objects; these solutions are also used for drying small things, even for delicate objects, unless they contain starch.

If it is wished to preserve an object for a few days without mounting it immediately, it is a very good plan to put a drop of this solution upon the object, and to place it under a bell-glass.

11. Glycerine. This is also well adapted for preserving microscopic objects, and especially for cells which contain starch, which latter substance continues unchanged by it. In glasses which exhibit lamination, for instance in the potash starch, the lamination is thereby continued for the first few hours; after 24 hours, however, it appears more clearly.

12. Copal varnish, or Canada balsam, also for the preparation of microscopic objects; these are only to be recommended for a few thin sections of wood, such as fossil woods. They both make the object more transparent than the solution of muriate of lime.

13. A tolerably strong solution of carbonate of soda in digesting root-wood, as well as hydrochloric acid for digesting fossil woods which have been converted into carbonate of lime. It is also recommended for examining the sweat-dots in the skin.

14. Acetic acid. This is very useful in examining animal tissues. It has the power of making the cell-wall clearer, whilst the nucleus becomes darker and more distinct. It also distinguishes phosphate or carbonate of lime from oxalate of lime, by dissolving the two former, whilst it has no effect upon the latter.

15. Very dilute chromic acid. It is used for the purposes of hardening tissues. It is especially useful in examining the structure of the retina.

16. Ammonia will be found useful in the same cases where caustic potash and soda are employed.

17. Nitrate of baryta is used as a test for sulphuric and phosphoric acids. Sulphate of baryta is insoluble in acids and alkalies, while phosphate of baryta is readily soluble in water.

18. Nitrate of silver in solution is used as a test for chlorides and phosphates. The white chloride of silver is soluble in ammonia, but insoluble in nitric acid. The yellowish phosphate of silver is soluble in excess of ammonia and nitric acid.

19. Oxalate of ammonia is employed as a test for lime, an insoluble oxalate being formed wherever lime is present.

This list of re-agents might be increased, as there is scarcely an operation performed in the laboratory that may not require some of them to be added. The above list, however, comprises those which will be found most useful.

In addition to the ordinary arrangements of the microscope, some forms of accessory apparatus will be found very useful. Some of these will be alluded to, and the following will also be found convenient.

1. A spirit lamp, which may be made of brass, tin, or
glass, fitted with a ground glass cap. It may be fitted with a stand, and will be found useful for submitting objects to heat. The objection to the employment of candles, or lamps, is the black smoke they produce.

2. A small warm bath will be found of use for drying objects previously to being mounted in Canada balsam.

3. Watch-glasses are useful for examining substances in fluids with low powers, as by this means a considerable depth of fluid is obtained for observation.

4. Microtome knives, those of about 1 inch and 1 inch broad, are useful for mounting and examining all kinds of bodies.

5. Thin glass, called cylinder-glass, of different degrees of thickness, is indispensable for placing over objects, especially those which require a soft or fluid when placed upon a slide.

6. Needles of various sorts are useful for fastening down minute organic bodies which are about to be submitted to dissection.

7. Scissors of various sizes will be found serviceable. These may be obtained of the surgeon's instrument maker.

8. Knives, scalpels, and razors, for cutting soft or hard objects, should be kept at hand.

9. A small narrow box will be found convenient for placing thin glass on the slides, as well as for placing or removing objects from the slides.

10. A glass-cutter's diamond is useful for cutting slits of glass on the slides, and in writing the names of preserved objects on the glass slides.

Cements of various kinds are necessary to the microscopic observer who wishes to preserve the objects he examines. They are used for making glass cells to contain objects, on the edges of which they are placed, and for attaching the glass slides, and making minute dissections. Small handles may be attached to them, rendering them more easy to work. Needles or pins may be employed for fastening down minute organic bodies which are about to be submitted to dissection.

3 F 2
We take the following account of several preservative solutions from Dr. Beale’s valuable work on ‘The Microcosm of London.’

Spirit and Water.—Mixtures of spirit and water of various strengths are required for preserving different preparations. In diluting spirit distilled water only should be employed; for if cold water or tap water be used, a precipitate of some of the salts dissolved in it is sometimes produced, which takes place, rendering the mixture turbid and unfit for use. Proof spirit will be strong enough for all general purposes, except for hardening portions of the brain or nervous system, when stronger spirit or alcohol is used. Two parts of proof spirit, about specific gravity ‘837, mixed with one part of pure water, makes a mixture of sp. gr. ‘916 to ‘930, which contains about 49 per cent. of real alcohol, and will therefore be about the strength of proof spirit. One part of alcohol, over-proof, to five parts of water, forms a mixture of a sufficient strength for the preservation of many substances.

Glycerine.—A solution of glycerine adapted for preserving many structures is prepared by mixing equal parts of glycerine with camphor water. The latter prevents the tendency to mildew. It may be used as other preservative solutions.

Glycerine is obtained by boiling oil with litchuge. The oleate of lead remains as an insoluble plaster, while the glycerine is dissolved. It may be rendered free from lead by passing through the retort. After passing through it; the clear solution, after filtration, may then be evaporated to the consistence of a syrup.

Thwaites’s Fluid.—This fluid has been much employed by Mr. Thwaites for preserving specimens of Desmodium; but it is also applicable to the preservation of animal substances.

Mix the creasote and spirit, stir in the chalk with the aid of a pestle and mortar, and let the water be added gradually. Next add an equal quantity of water saturated with camphor. Allow the mixture to stand for a few days, and filter. In attempting to preserve large preparations in this fluid, I found it always became turbid, and therefore tried several modifications of it. The solution next to be described was found to answer very satisfactorily. Water may also be impregnated with creasote by distillation. It should be remarked that M. Strauss-Durckheim has succeeded in preserving preparations in camphor-water only.

Solution of Naphtha and Creasote.

Creasote . 3 drachms.
Wood Naphtha . 6 ounces.
Distilled Water . 64 ounces.

Mix first the naphtha and creasote, then add as much prepared chalk as may be sufficient to form a smooth thick paste; afterwards add, very gradually, a sufficient quantity of the water, which must be well mixed in a mortar. Add two or three small lumps of camphor, and allow the mixture to stand in a lightly-covered vessel for a fortnight or three weeks, with occasional stirring. Pour off the almost-clear superfluous fluid, and filter it if necessary. Preserve it in well-corked or stopped bottles.

I have some large preparations which have been preserved in upwards of a pint of this fluid, for more than five years, and have remained perfectly clear and unaltered. Some dissectors of the nervous systems of insects have kept excellently—the nerves keeping their colour well, and not becoming at all brittle. Two or three morbid specimens are added, and an excellent state of preservation; the colour being to a great extent preserved, and the soft character of the texture remaining. I have one preparation mounted in a large gutta percha cell, containing nearly a gallon of this fluid.

Solution of Chromic Acid.—A solution of chromic acid will be found well adapted for preserving many microscopic specimens. It is particularly useful for hardening portions of the nervous system previous to cutting thin sections. The solution is prepared by dissolving sufficient of the crystallized acid in distilled water, to render the liquid of a pale straw colour.

The crystallized acid may be prepared by decomposing 100 measures of a saturated solution of bichromate of potassae, by the addition of 120 to 150 measures of pure concentrated sulphuric acid. As the mixture becomes cool, crystals of chromic acid, which should be dried and then pressed on a porous tile, by which means the greater part of the sulphuric acid is removed, and the crystals obtained nearly pure.

Preservative Gelatine.—

Gelatine . 1 ounce.
Bottle of spirits . 6 ounces.
Spirits of Wine . 4 ounces.
Cresasote . 6 drops.

Soak the gelatine in water until soft, and to it add the honey, which has been previously raised to the boiling-point in another vessel. Next let the mixture be boiled, and after it has reduced to the strength of a syrup the creasote dissolved in the spirits of wine is to be added. Lastly, filter through thick flannel to clarify it. When required for use, the bottle containing the mixture must be slightly warmed, and a drop placed on the preparation upon the glass slide, which should also be warmed slightly. Next, the glass cover, after having been breathed upon, is to be laid on with the usual precautions, and the edges covered with a coating of the Brunswick black varnish. Care must be taken that the surface of the drop does not become dry before the application of the cover, and the inclusion of air-bubbles must be carefully avoided.

Geoddy’s Solution.—

Sodium . 4 ounces.
Alum . 2 ounces.
Corrosive Sublimate . 4 grains.
Distilled Water . 4 pints.

Mix and filter. This solution may for most purposes be diluted with an equal bulk of water. For preserving delicate preparations it should be even still more diluted.

Burnett’s Solution.—This fluid has been patented. Its preservative properties appear to depend upon the chloric acid of zinc. A strong solution of chloric acid of zinc forms a very powerful antiseptic, and also possesses the property of absorbing noxious odours, &c.

Other saline solutions.—Many other saline solutions have been employed by different observers. Of these, a saturated aqueous solution of chloric acid of calcium, free from iron, has been much recommended for preserving specimens of bone, hair, teeth, and other hard structures, as well as many vegetable tissues (Schacht). A solution of alum in the proportion of 1 part of alum to 16 parts of water has been found to answer pretty well for some substances. Ganna’s solution, which consists of 1 part of acetate of alumina—dissolved in 10 parts of water; solutions of common salt (1 part to 5 parts of water, with a little camphor), corrosive sublimate, mercury, sulfidure of bismuth, arsenious acid, ortho phate of zinc, and solutions of several other salts, have been recommended as preservative solutions, but their employment has not been always attended with the most satisfactory results. Arsenical hydrocyanic acid has also been recommended for the preservation of animal substances, but it is not adapted for microscopical preparations.

Canad Balsam forms a most useful agent for mounting various substances; and the structure of many can only be clearly made out when they are examined in this menstruum. In this method of mounting objects no cells whatever are requisite. The balsam should be pale and old. The glass slides must be warmed before the balsam is put on, and for this purpose they may be floated on a pie of wooden forceps, or in a pair of common forceps, the tips of which are covered with cork, and heated over a spirit lamp or upon a brass-plate. The latter plan is the most convenient when several preparations are to be mounted at the same time, but they may be arranged in a row along the plate, and the balsam placed upon each slide as it becomes hot.

The Canada balsam may be heated after it is placed upon the slide to allow the air bubbles entangled in it to rise to the surface before it is applied.

The slide being warm, and the small quantity of Canada balsam sufficient to contain the preparation having been placed upon it, it must be gently moved about while the balsam is still liquid, until a film has floated to the surface and collected together towards one spot. A pointed wire or needle should then be taken, and all the bubbles either drawn out upon the end of it
which may be readily effected, or broken by the wire after it has been heated. In those cases in which the preparation is not detached from the glass slide upon which it has been allowed to dry, it is only necessary to place the drop containing the specimen between the plates of a slide, with precautions; afterwards the thin glass cover may be applied. When the preparation has been dried separately over the water-bath and cleaned, it may be taken in a fine pair of forceps, gently warmed, and carefully placed in the hot and penetrating fumes of chloroform. Having been thoroughly wetted by the balsam, and all adhering air-bubbles removed, it may be placed in the position it is intended to occupy. The thin glass cover, adapted to the size of the preparation having been previously warmed, may then be taken in a pair of forceps, and, after being held over the warm balsam for a minute, allowed to fall gradually upon the preparation (beginning at one side), until it becomes perfectly wetted with the balsam. The glass may now be slightly pressed in order to force out the superfluous balsam, and the preparation allowed to cool.

We now proceed to give a few directions for the examination of particular objects, more especially animal tissues, as these of all others are the most difficult to manage. In the examination of tissues containing blood-vessels, ducts, or other tubular organs, it is frequently most desirable that injections should be made before they are submitted to the microscope. This operation requires great delicacy. A very small amount of fluid, of the consistency of honey, and, according to the color of the tissue, mixed with it, is injected. The following general rules for injection are given by Dr. Beale:—Great attention should be paid to the cleanliness of all the instruments to be used in injecting. The syringe should always be kept scrupulously clean and in good order, and the injecting-cans should be carefully covered, to prevent the ingress of dust. Before commencing the operation, plenty of warm water should be at hand; and the subject should be allowed to soak for some time in a basin of hot water, before it is attempted to inject it, in order that it may be thoroughly warmed through. The temperature of the water must vary according to the degree to which the injection is required to be heated: if size and vermillion be used, the water need only be warm; but if melted wax be employed, the water must be so hot that the hand can scarcely be borne on it.

The length of time which the preparation is allowed to soak must depend upon its bulk; and the water should be changed as soon as it becomes at all cool. With respect to the length of time to allow for this treatment, there are no absolute rules can be given. Generally, it may be remarked that we should not attempt to inject while the ‗rigor mortis‘ lasts. Many days may in some cases with advantage be allowed to elapse, particularly if the weather is cold, which will gradually destroy the rigor mortis just after death. As a general rule, the more delicate the tissue, and the thinner the vessels, the sooner should the injection be performed. Many of the lower animals, annelids, mollusces, &c., and fishes, should be injected soon after death. In making minute injections of the brain, only a short time should be allowed to elapse after the death of the animal, before the injection is commenced. Injections of the alimentary canal of the higher animals should be performed earlier in the morning, and only a short time before death. When the preparation is warmed through, the injection properly strained, and the pipe fixed in the vessel, we may proceed carefully to inject, taking care that the injection is kept at a proper temperature, allowing it to remain in the warm water-bath during the operation.

The air should be first withdrawn from the upper part of the vessel by means of the syringe, after which the stopcock is turned off and left attached to the pipe. The syringe is then connected with a cannula balance, and two or three times with warm water, is nearly filled with injection, which must be well stirred up immediately before it is taken. The syringe should not be quite filled, in order that the air in the pipe may be made to expand, and may be allowed to come out of the accidental of the piston, before any of the latter is forced into the vessel. The end of the syringe is then to be pressed firmly into the upper part of the stopcock, with a slightly screwing movement.

The piston is now very gently forced down by the thumb until the syringe has been nearly emptied, when the stopcock must be turned off, and the syringe refilled with warm injection as before.

Care must always be taken to keep the syringe in an inclined position, in which it may be in it may remain in the upper part; and, for the same reason, all the injection should not be forced out, for fear of the inclosed air entering the vessels, in which case all chance of obtaining a successful injection would be destroyed.

After a case of fluid having been injected, it will be necessary to use a greater amount of force, which, however, must be increased very gradually, and should only be sufficient to depress the piston very slowly. If too great a force is employed, extravasation will be produced before the capillaries are filled. Gentle pressure, followed by an increased pressure, kept up for a considerable time, will cause the minute vessels to become slowly distended without giving way to any great extent. At the same time it must be borne in mind that extravasation frequently occurs at various points in a successful injection; but the longer this event can be kept off, the more likely are we to succeed.

In order to examine the structure of many tissues, it is necessary to obtain a section sufficiently thin to permit the transmission of the light readily, and so evenly cut, that the minute structure of the tissue may be submitted to examination in every part of the section. The difficulty of making thin sections of many textures is often very great, and, to effect it, it is necessary, besides the usual mechanical operations becomes necessary. Sometimes we require to cut a thin section of a soft pulp texture, which can scarcely be touched without injuring its delicate structure, and altering the position of its constituents; while, in other instances, we have only a very small portion of a substance so hard that steel tools will scarcely scratch it, such as the enamel of teeth, fossil teeth, &c.

Previous to the examination of a tissue, boiling is frequently of service. For instance, the fibres of which the crystalline lens is composed are best shown after boiling the lens in water. The branched muscular fibres in the tongue of the frog, and in other situations may be made out very readily by boiling the organ in water for a few moments, and then tearing up small portions with fine needles. Beautiful sections of muscular fibre can often be obtained after the texture has been boiled in water. Various glands and other textures often require to be boiled some time in water, in order to harden them sufficiently to enable us to cut thin sections; but in all cases the microscopical characters of the recent texture should be examined, as well as that which has been hardened by boiling. Small portions of tissue can be readily boiled in a test-tube over a spirit-lamp. In this way we wish to get rid of the soft and more pulpy part of a tissue, in order to subject the more dense and fibrous portion to examination. This object is usually effected by soaking the tissue in water for some little time, which then produces a condition known as ‘softening‘, which means the softer portions are gradually washed away. Soaking in water frequently enables us to tear up a tissue very readily with the aid of needles, and thus to demonstrate its structure. Occasionally it is found necessary to press the tissue, and rub parts of it together, before the soft pulp portions can be got rid of. In this way we may demonstrate the supporting or trabecular tissue of the apleen, and the areolar and vascular tissue of the liver, &c. Thin sections of kidney, liver, and other organs, can be obtained in a similar manner, when the matrix is to be subjected to examination separately.

Thin sections of various tissues can frequently be obtained only by first drying the substance thoroughly, and then cutting off a thin shaving with a sharp knife. In this way we may prepare specimens of skin, mucous membrane, and many other tissues, which are often most advantageously prepared. The tissue is stretched on a board with pins and then allowed to dry, when a very thin section can be cut off and examined in a microscope. This drying may be speeded up by exposing it for a short time, in which case, when subject to examination, it will be often found to have regained its first appearance. Portions of muscular fibre, the tongue, skin, and many other tissues, can be much advantageously prepared in this manner, as they may be cut off with a sharp knife readily obtain exceedingly thin sections, which could not be procured in any other manner. The drying may be effected in a warm room, or in a current of air. A high degree of artificial heat should be avoided.

When the inorganic portion of a tissue which we wish to
examine is not altered by exposure to a red-heat, recourse may be had to ignition, in order to get rid of the animal matter. In this way crystals of carbonate and phosphate of lime, and granules of siliceous matter are removed. The organic material with which they were combined. The beautiful siliceous shells of the Distomaces may be separated from organic matter by a similar process. The ignition should be carried out in a small platinum boat, or upon a small piece of platinum foil. The carbonaceous residue must be exposed to the dull red-heat of a spirit-lamp for some time, until only a pure white ash remains, which will be found to contain the objects of our search in a very perfect state. To the best of our power, this process can be carried out without the least injury to the shells, or the organic matter contained, the ash should be treated with strong nitric acid, which will dissolve any carbonate or phosphate. The insoluble residue may then be washed and dried, and subjected to microscopic examination while the product of the turgescence in Canadian balsam. In this method is superior to that of boiling in nitric acid in order to remove the organic matter. Both processes may however be employed where only the siliceous residue is wanted, but if we require the salts of lime, ignition at a dull red-heat is alone applicable.

In order to subject a portion of tissue or other substance to examination by transmitted light, the following plan is adopted:—One of the glass slides is carefully cleaned, and the thin section of tissue which has been removed by the aid of the knife or scalpel, is placed on the centre of the drop of clean water is then added, and the whole covered with a square of thin glass, also perfectly clean. If the surface of the thin glass be gently breathed upon, it becomes very nearly dry. The slab may then be revellled with needles, or, if necessary, any other operation performed before covering it with the thin glass. If the substance be covered with too much soft pumpy matter, it may be slightly washed in water before being placed upon the slide, or a jet of water from the wash-bottle may be directed upon it. Thin sections will require to be laid flat upon the slide, with the assistance of needles and forceps.

Hard tissues require a different treatment. Here the great object is to make them thin enough for the object to be seen by transmitted light. Many hard substances, such as nail, horn, and dried animal textures, may be cut with a strong sharp knife, or with a razor; an operation which is easily performed by placing the substance upon a piece of soft deal board, and after cutting a smooth edge, removing a thin shaving, which may be examined dry or in fluid, or may be placed in Canadian balsam, as occasion may require.

Blacksmiths, tool-makers, and fossilised rocks, should be first cut into very thin sections with the aid of a sharp saw. These sections should then be pared down to the necessary thinness upon a hone or smooth stone. This may be effected in the following manner:—The section, after having been cut with the saw, is placed on the ground, and before it can be subjected to examination. It may perhaps be as much as the tenth of an inch in thickness when the grinding is commenced, but by rubbing it for a short time upon a smooth stone it may be reduced to the proper degree of tenuity. Stones which are well adapted for this purpose are the 'Charley Forest' stones, the Turkey stones, or the Water of Ayr stones, about an inch or more in width, and six inches in length. Each of the four sides should be perfectly smooth. Other stones, or even a piece of slate, answer also very well, and may be procured at much less cost. The stone is wetted with a little water, and the section rubbed up and down with the finger, or with a piece of cork or leather. As a matter of fact, it is imbedded in the section slightly in a piece of warm gutta percha, which should extend only over a very short distance beyond the edges. This is to be rubbed up and down on the wet hone, water being added as required, till the surface is perfectly smooth, when the section is to be taken off, turned round, and ground down on the opposite side until it is sufficiently thin. The section may also be ground down expeditiously by rubbing it between two hone. If very thick, it will be better to reduce it somewhat with the aid of a flat file, and commence the grinding. After being ground to what is considered the proper thickness, the section may be placed in the microscope, when numerous dark lines will be found all over the surfaces; these must be removed by polishing. The deepest of the scratches may be removed by polishing the specimen upon a very smooth part of the hone quite dry.

Tooth require a little more attention than other hard sub-
stances. They should be first ground down upon a lapidary's wheel, or upon a dentist's emery wheel. Sections can also be readily cut with a diamond saw, by iron wheel, the edge of which is dressed with diamond dust.

The thin section is now to be soaked for a short time in ether to remove the fatty matter, and then allowed to dry. It is to be subjected to examination in the dry way, mounted with water, turpentine, or Canada balsam. In examining the different appearances in each case should be carefully observed.

The cartilaginous basis is to be examined also in this sections, which may be cut either before macerating in acid, or after. The cartilage becomes very soft in ten days, or more. A strongly acid will become soft in four or five days, when thin sections of different parts may readily be cut with a sharp knife.

The denticial tubes may be isolated from each other by loosening them from one another, and changing the fluid for a few hours in dilute caustic soda or potash. It is better in this investigation to cut the thin section before macerating in acid, or to macerate the tooth until moderately soft, and then remove a thin section, which is to be further exposed to the action of the strong acid.

A mixture of sulpharic and hydrochloric acids has also been recommended.

The examination of fluids does not require so much art as that of solid matters. Where it is wished to examine the whole of the contents of a fluid, all that is necessary is to place a drop of the fluid on the middle of a slide, and cover it with a square of thin glass. It frequently happens however that it is the matter suspended in a fluid that it is desirable to examine. Under these circumstances the fluid should be placed in an ordinary test-tube, and after allowing the deposit to settle, the supernatant liquor should be poured off, and a drop of the deposit conveyed to the glass slide. In other cases a pipette may be made use of to draw up the deposit from the bottom of the test-tube or other vessel in which it may be held. In examining a fluid the deposit should be placed under the microscope, and the contents of the bag placed on the slide. In this way the Desmidaceae and some of the larger Foraminifera are best procured for examination.

When the quantity of deposit is very small, the following plan will be found of practical utility. After allowing the lower part of the fluid which has been standing to flow into the pipette as above described, and removing it in the usual manner, the finger is applied to the orifice, in order to prevent the escape of fluid when the upper orifice is opened by the removal of the finger. The upper opening is then carefully closed with a piece of cork. Upon now removing the deposit from the orifice of the pipette, a small drop of the glass slide is placed under the petri-dish, which is allowed to rest upon it for a short time. It may be suspended with a piece of string, or supported by a small retort-stand. Air tracts of deposit will subside to the lower part of the fluid, and by allowing the air to escape it will be possible to place the glass slide, which may be removed and examined in the usual way.

Another plan is to place the fluid with the deposit removed by the pipette in a narrow tube, closed at one end, the size of which is neither less than a quarter of an inch in diameter. This may be inverted on a glass slide, and kept in this position with a broad elastic India-rubber band. The deposit, with a drop or two of fluid, will fall upon the slide, but the escape of a further quantity is prevented by the nature of the arrangement.

Amongst the fluids of the human body which with advantage be submitted to examination with the microscope, there is none of more importance than the urine. The fluid being the great means which nature employs to rid the system of the used-up and effete matter of the body, becomes an index by which the completeness, redundancy, or insufficiency of this function may be examined. The following hints for the examination of this fluid will be found useful.

The urine which is to be examined should be collected in sufficient quantity, in order to obtain sufficient of the deposit for examination.

In all cases the urine should, if possible, be examined without delay after its secretion, and, in many instances, it is important to institute a second examination after it has been allowed to stand for 24 hours. Some specimens of urine pass into decomposition within a very short time after they have escaped from the bladder; or the urine may even be drawn from the bladder actually decomposed.

In other instances, the urine does not appear to undergo
Acetic acid causes the membrane of the corpuscle to become more transparent and clear, and to swell up from endosmosis. After the application of this re-agent the blood-corpuscle may be seen to be invisible, but not dissolved by it. Strong hydrochloric and nitric acids do not dissolve the globules; with the latter re-agent the outline is often rendered darker and thicker, while the entire globule becomes semi-transparent, and then again soluble in ammonia and alkalies. They are rendered darker, and the walls corrugated, by the acid of the gastric juice, and after remaining in acid urine for some time a similar change occurs; hence the black colour of blood which has been infused into the stomach, and the dark smoky hue of acid urine containing blood.

We have before spoken of the crystals to be obtained from the blood. These crystals are very readily obtained by diluting blood with water. A drop of blood may be placed upon a glass slide, and after the addition of water, alcohol, or ether, the whole should be lightly covered with thin glass. A hair, or a small piece of thin paper or wood, may be placed between the glasses, in order that a stratum of fluid of sufficient thickness be retained. Whenever it is possible, it is preferable to use desribinated blood. Often the corpuscles and a little serum may be removed from the clot by firm pressure, and from this very perfect crystals may frequently be obtained. The blood-corpuscles become ruptured, their contents escape, and the crystal lies as the solution gradually becomes concentrated. The time which elapses before crystallisation takes place varies from an hour to several hours or days in different specimens of blood. Crystals may also be obtained in a similar manner from urine.

The form of the crystal often varies slightly in the same specimen, but the blood of different animals yields crystals of very different forms. The prismatic form is that most commonly obtained from the blood of man, the Carvuscoro, and fishes. Tetrahedral crystals appear most common in some of the Rodentia, as the guinea-pig, while six-sided tables are formed in the blood of the squirrel, mouse, and some others. Teichmann has succeeded in obtaining crystals in addition to a very large quantity of water at a very low temperature.

The crystals form more readily in daylight than in the dark, but most rapidly when the slide is exposed in the light of the sun.

Guinea-pig's blood crystallises in the course of half an hour, or even sooner if it be diluted with a little water or alcohol. Dog's blood also crystallises in the course of a short time upon the addition of a little alcohol. Human blood, on the addition of the same, only crystallises when just removed from the body, but more quickly if the blood has been drawn a few hours.

It is obvious from what has been said above that the microscope is one of the most important instruments of the pathologist. The method of research that it permits the character of these bodies the student should be perfectly familiar as soon as possible; and, as they may be obtained without the slightest difficulty, this is easily effected.

For the nature of the deposits found in the urine, see the article Urine.

The examination of the other fluids of the animal body presents little difficulty. Next to the urine the blood is of most importance. In order to examine the blood, a small drop is placed upon a glass slide, and covered with thin glass, which is to be pressed down until a very thin, transparent, and almost colourless stratum only remains. In this manner the individual globules cannot be seen distinctly, a little syrup or serum must be added; but it is better to avoid this, as the red corpuscles may be lost in it. Upon focussing, the red globules will appear to present a dark centre and light circumference, or the reverse, according as the focus is altered, and here and there a white corpuscle may be seen.

If a little strong syrup be added to a drop of blood, the corpuscles will be found to have become flatter from exosmosis of a part of their contents; while, on the other hand, if placed in water, they become spherical from endosmosis, and contain nearly the same amount of similar density to that in the interior of the corpuscle; and in this manner, as Dr. Rees expresses it, we may take the specific gravity of a blood-corpuscle, if we ascertain the specific gravity of the solution which has been added to the blood.
part of the gentle-urinary mucous membrane, or to more general disturbance in the changes which take place in primary and secondary assimilation.

"Fatty Degeneration. Of late years the remarkable changes which take place, and which have been described under the name of Fatty Degeneration, in some of the highly lipidic tissues, has led to the supposition that the properties become changed, and their functions impaired, or altogether destroyed, and have been undergoing careful investigation by a vast number of highly-talented investigators.

"The recent discovery of a state of fatty degeneration affecting the arteries of the brain, in the majority of cases of apoplexy, by which the strength of their coats becomes deteriorated, and their elasticity entirely destroyed, would lend force to this supposition. It is well known that the consequences of arteriosclerosis depend upon complicated changes affecting nutrition, than upon the presence of a condition of plethora or hyperemia, as was formerly supposed and acted upon.

"The connection between fatty degeneration of the margin of the cornea (arcus senilis), and similar changes taking place in the muscular tissue of the heart (a subject which has been carefully investigated by Mr. Canton), or in the cerebral vessels, must be regarded with great interest by every microscopist.

"The microscopic examination of the matters vomited in certain cases has proved to us that the presence of minute fungi, originally discovered by Professor Goodair, and named by him *Saccharoma ventriculi*, occurs in connection with the mucous membrane of the stomach. These remarkable cases are much more frequently met with than was formerly supposed, and form an exceedingly interesting class of diseases. [Entomotyza, S. 2.]

"For the detection of Impurities in Food and Drugs the microscope is of the greatest importance and aid, and there are several other purposes to which it may be applied.

MIDDLESBOROUGH. [YORKSHIRE.]

MIDDLETOWN. [DURHAM; LANCASHIRE.]

MIDDLETOWNITE. [MINERALOGY, S. 1.]

MIDDLETOWN. [CONNECTICUT.]

MIDDLETOWN. [ROCKISHER.]

MIDDLETOWN, county of Cork, Ireland, a post- and market-town, and the seat of a Poor-Law Union, is situated near the head of the northern branch of Cork Harbour, 51° 05' N. lat., 8° 15' W. long., 134 miles by Cork by road, and 1744 miles by S.W. by N. from Dublin. The population in 1851 was 3676, besides 2334 inmates of the workhouse. Middletown Poor-Law Union comprises 19 electoral divisions, with an area of 109,286 acres, and a population in 1861 was 3270. Middletown consists mainly of a spacious and well-built street between the Avoncharia and Roxborough rivers, terminating at each end in a bridge. In the town are a vestry church, a Roman Catholic chapel and nursery; a Free Church school, founded by the Society of Friends in 1822, by the Pipers in 1833, and by the Wesleyans in 1837, with 20 scholars in 1852, two National schools, a court-house, a market-house, a bridewell, a fever hospital, and a district dispensary. There are also distilleries, breweries, corn-
Vessels of 300 tons ascended to Bail-lick, within half a mile of Mildeston; and at the port of Ballincurla, about a mile below the town, large ships are made of corn and other provisions. Quarter and petty sessions are held on every Thursday at Boxford, July 6th, October 10th, and November 22nd. The town and neighbourhood are the property of Viscount Mildeston.

MILBOURNE. [Somersetshire.]

MILBOURNE CASTLE. [Somersetshire.]

Military and Naval Forces. Under 'Great Britain,' in Penny Cyclopedia, vol. xi., p. 490, the state of the army and navy of the United Kingdom, in 1838, was given. Since that period, partly in consequence of the deficiencies made apparent during the war against Russia, several important regulations have been introduced into the army. To the branches of the Artillery and the corps of Engineers, commissions were thrown open to competitive examination, with a marked success. After a certain time, not yet fixed (April, 1858), the first entrance to these corps is to be made at Sandhurst Military College, but it would appear that, with very slight restrictions, these corps, as well as staff appointments, will still be open to public competition. The competitors must not be less than 16, nor more than 18, years of age; they must have testimonials of responsibility, and they will have to be nominated by the Commander-in-chief, before they can be received for examination.

To the main body of the army facilities have been affor ded for frequent fighting and increasing demobilization from the ranks. The use of the Minie and Enfield rifles have been generally adopted throughout the army, and prizes have been instituted for the encouragement of skill in their use. Some alterations also have been made in the clothing and equipment of the soldiers, while as far as they have gone have been improvements, but which might be judiciously extended. A permanent camp was also formed at Aldershot, near Bagshot, in 1855, where field operations could be effectively performed; and another in Ireland. Also, in consequence of a medical report showing the fearful mortality in the army arising from sickness, an investigation was ordered, which resulted in showing that the main cause of a mortality which considerably more than doubled the average rate, and greatly exceeded even that of the most deleterious and dangerous trades, was the ill-constructed and crowded state of the barracks. In March, 1858, General Peel, the Secretary for War, announced that surveyors had been appointed to examine the barracks, and that prompt means would be taken to remedy these evils.

The number of officers, non-commissioned officers, and rank and file, voted for the effective service of the United Kingdom for the year ending March 31, 1857, the close of the financial year, was 33,940,704. The troops in the East Indies, who amounted to 28,583; the number of the non-effective service was 2,000; the estimated charge was 34,195,041/; an increase of 30,378 men, and 2,595,077/ of charge, over the preceding year. The revised estimate was subsequently reduced to 30,240,964/.

For the year ending March 31, 1858, there were voted 125,756 men, with 11,786 horses, a decrease of 119,920 men from the preceding year. The troops in the East Indies had increased to 30,157, with 2,812 horses.

For the year ending March 31, 1859, the estimate was as follows:

<table>
<thead>
<tr>
<th>Officers</th>
<th>Non-Comm. Officers</th>
<th>Rank and File</th>

There are three regiments of Life Guards and Horse Guards, one battalion of Horse Artillery, 7 regiments of Dragoon Guards, and 16 regiments of Dragons according to the Army List (1 to 17, the 6th having been disembodied), but the estimates provide for 18 regiments, the 5th being restored; one regiment of Royal Artillery, one of Royal Engineers, a medical Train, a Medical Staff, and a Commissariat Staff. The Infantry of the Line consist of three regiments of Guards, 99 foot regiments, and a Rifle Brigade. There are three West India Regiments, and seven Colonial Corps.

In Jan. 1858, according to the Army List, there were 4 Field-Marshals, 67 Generals, 89 Lieutenant-Generals, and 290 Major-Generals.

At the beginning of 1837 the army of the East India Company, independent of the Queen's troops, amounted to about 390,000 men. Here 34,630 were cavalry, and the 74,920 artillery, horse and foot, with 516 pieces of cannon. The European officers of this force numbered 6215.

This was, of course, before the breaking out of the Indian mutiny. The Bengal army mutinied almost to a man, and what remains of that force is now (April, 1858) in arms against us. Some disaffection has also probably decreased the numbers of the Madras and Bombay armies. On the other hand, the number of royal troops has been greatly increased; but so many are on passage or their passage, or under orders to proceed thither, that it is not possible to state the precise numbers. On the whole an addition, from home and from some of our colonies, of more than 50,000 has been forwarded to India, though incessant fatigue, the climate, and frequent disease, have so much diminished the efficiency of the men. The Queen's troops in India for 1856-9 are estimated as follows:—

The amount voted for the year ending March 31, 1857-8, was 11,443,236/; for 1858-9 it was 11,750,000/. Of this in the first year 4,385,017/, and in the last 4,361,092/, were expended on regiments and staff payments, and allowances, but 680,000 in the last year was to be paid by the East India Company on account of the excess of number of men sent to India.

The amount voted for the Embodied Militia for the year ending March 31, 1859, was 650,000/; and for Volunteer Corps, 80,000/; for 1868 the amount had become 60,892/.

The sum expended on the effective service of the army in 1857-8 was 9,321,092/; the estimate for 1858-9 was 9,285,319/; on the non-effective (pensions, rewards, and allowances,) 2,221,875/ and 2,240,068/.

In the Navy much attention has been given to instructing the seamen in the working of great guns. This has been eminently successful, and the precision and rapidity with which they can now be directed and discharged has added materially to their efficiency for destructive purposes.

In 1857 the total navy consisted of 260 sailing vessels, carrying 6722 guns, and 202 steam vessels carrying 6505 guns, besides 160 gun-boats. These were manned by 42,776 men, including officers, and there were in addition 16,000 marines.

In Jan. 1858 there were in commission 648 vessels of various sizes, sailing and steam-propelled vessels, mounting 15,716 guns, and 120 steam-steam-masted ships of war, 5 mounted 131 guns each, and 22 others mounted from 101 to 120 guns each. The arming of vessels has however undergone considerable modification, the chief objects aimed at now are facility of motion in the ships, and weight of metal and length of range of the guns.

Of the Royal Marines there are 104 companies, of which the total strength is estimated at 15,000. They are commanded by 3 generals, 3 lieutenant-generals, 5 major-generals,
4 colonels and commandant, 5 colonels and second commandants, 19 lieutenant-colonels, 130 captains, 176 lieutenants, and 50 second lieutenants. There are also depots of Marine Artillery, with 1 colonel and second commandant, 2 lieutenant-colonels, 14 captains, 37 first lieutenants, and 9 second lieutenants.

The total expenditure on the navy for the year ending March 31, 1857, was 14,644,514, an amount less by 1,904,100 than that of the estimate of the gross sum. The vote for 1858-9 was for 44,380 seamen, including coast-guards, &c., and 15,000 marines; the estimate of the expenditure was 9,680,000, including the effective and non-effective services.

The military and naval forces of the principal foreign countries for 1857 (where not stated to the contrary), are given in the following table:

<table>
<thead>
<tr>
<th>Country</th>
<th>Navy</th>
<th>Foreign Service</th>
</tr>
</thead>
</table>
| Austria         | 84 regiments of infantry,     | 14 frontier regiments, | 56,320 men: 23 battalions of light infantry, numbering 23,534 men; with a division or depot of light infantry, numbering 6,884 men. The cavalry consisted of 8 regiments of cuirassiers, 8 of dragoons, 12 of husars, and 12 of uhans, amounting in the whole to 70,376 men, with 60,784 horses. The artillery numbered 58,614 men, with 1,544 pieces of cannon and 10,000 staff corps officers, 1,162 men; there were 6 batteries of pioneers, numbering 9,217 men, with 3,880 horses; and 20,000 gendarmerie (these are the armed police), in 12 regiments. There are also many other military establishments, such as the military schools, with 1,029 professors and other petty officers, 2,487 men, and 21 depots, with garrison and frontier battalions, &c. The Austrian navy numbered 101 vessels, including 62 gun-boats, and 9 transports, the whole carrying 950 guns. It contains one vessel of 100 guns, 5 frigates, carrying together 165 guns, 3 screw-steamer frigates, carrying 125 guns; the remainder are corvettes, brigs, and smaller craft. The population, at the end of 1854, was 39,411,309, exclusive of the military.

Bavaria had 154,526 infantry; 28,879 cavalry; 24,700 artillery and pioneers; 9,000 marines, and 6,000 gendarmerie; 28,000 men, with 90 pioneer corps, 12,000 horses; 12 battalions of cavalry, and 14 battalions of infantry. The force also consists of 3,000 men of the Rhine, 54,000 infantry and 2,000 cavalry. The population was 4,541,595.

Belgium possessed an army of 16 regiments of infantry, numbering 66,350 men; 7 regiments of cavalry and gendarmarie, numbering 8,502 men, with 7,855 horses; 4 regiments of artillery, numbering 7,600 men, with 152 pieces of cannon; one regiment of engineers, numbering 1,690 men; and a communication corps, numbering 1,000 men, is the gendarmerie establishment, and forms in effect a total force of 100,000 men when on a war footing. The population was 4,630,928.

For Denmark the number of men is not stated, but in time of peace it has a general staff, a corps of engineers, 2 regiments of artillery and pioneers, 90 pioneer corps, 12,000 horses; 12 battalions of cavalry, and 23 battalions of infantry. There besides a corps of reserve, composed of cavalry, infantry, and artillery. The navy numbered 119 vessels, mounting 913 guns, of which 4 are ships of the line, and 11 are steam-vessels, carrying 135 guns; of the remaining, 67 are gun-boats, 17 transports, and other small vessels. In 1856 the total population of Denmark, together with Schleswig Holstein, and other dependencies, was 2,600,000.

In France, the infantry of various sorts numbered 220,268 men, the cavalry 69,988, the artillery 34,582, the gendarmerie 22,719, the engineers 9068, the staff 4345, the military train 4971, the veterans 1135, military interands 1029, the foreign body (Algiers) 6011, riflemen and indigineous cavalry (Algeria) 6767: a total of 378,015 men. In 1856 the total number had amounted to 677,836 men, of whom there were in France 310,347, in Africa 64,253, engaged in the war in the East 197,597, and in Italy 62. The navy in 1857 consisted of 263 vessels, of which 10 were of 190 guns each, 10 of 100, and 5 of 80; there were 50 frigates of from 60 to 40 guns each; the rest were smaller vessels, corvettes, brigs, and a few steam-vessels of lesser size. The population was 36,039,364.

Hanover had a total land force of 29,535 men, of which 20,464 were infantry, 3078 cavalry, 257 engineers, 2866 artillery, 441 gendarmerie, and 33 staff officers. The population was 1,515,777.

Netherlands had 15,600 men of an army amounting in the whole to 143,588 men. Of these 74,914 were infantry, 6736 were cavalry, with 6000 horses; 6322 were artillery, with 1347 horses; 2850 were engineers. These formed the active army, and there were in reserve 45,400 infantry, and 300 cavalry. In the fleet there were 105 ships, altogether 833 guns; there were 2 ships of the line, 5 sailing and 14 steam frigates; there were 50 mortar and gun-boats, and other small vessels. The total population of the Two Sicilies amounted to 7,126,457. The army of the Netherlands amounted to 58,495 men, of whom the infantry, including the staff, numbered 43,583 men; the cavalry 4480; the engineers 685; the artillery 6807; a corps of pontoniers, numbering 213; and 5 companies of gendarmerie. The navy consisted of 6 ships of the line, 5 frigates, some of them steamers; 16 smaller warsteamers; 68 gun-boats; the remainder were smaller craft. The total carried 1934 guns. The population of the Netherlands, exclusive of the colonies, was 5,647,517. The army of the United States consisted of 11,984 men, with 3484 men of the navy, 9,410 cavalry, with 1368 horses, 1524 artillery, with 199 horses, and 840 pieces of cannon; and 290 engineers; these, with the staff, sanitary corps, &c., make a total of 20,620 men in active service; and there are also municipal police, veterans in retirement, and others, with a reserve of 4996, making a total of 31,845 men. These were independent of 17,253 men, forming the armed forces of its foreign possessions. The navy consisted of 59 vessels, of which 5 were disarmed, and 5 were adverse to the general movement; the remainder consisted of 55 vessels, carrying 398 guns, and 3,600 men. There were 9 sailing frigates carrying 36 guns, 2 steam-frigates carrying 21 guns, 36 gun-boats with two guns each; the rest small vessels, some of which were steamers. The population in 1856 was 17,822,531, in which you may include 8 regiments of engineers, &c., forming a principal part of the light cavalry, numbered 127,800 men. The navy was divided into four divisions: the Baltic fleet, the White Sea fleet, the Black Sea fleet, and the fleet of the Pacific Ocean. The first consisted of 6 sail of the line, 3 frigates, and 20 other ships; the second consisted of 55 vessels, carrying 3 steam-frigates, of which the number of guns is not stated; the second division consisted of 6 sail of the line, mounting 496 guns, and 8 frigates, of which the armament is not given; the third division consisted of 5 sail, but of these 3 guns is not given; and the fourth division consisted of 8 sail of the line, mounting 690 guns, 5 frigates, and 2 steam-vessels. There were also a considerable number of gun-boats, both rowing-boats and steam-boats. The total population of the empire of Russia in 1856 was 58,937,437.

In Sardinia the army consisted of 29 regiments, numbering 36,410 men; 10 battalions of riflemen (Bersaglieri), with 3657 men; 9 regiments of cavalry, with 5175 men, and 4309 horses; 3 regiments of artillery, with 4200 men, and 1302 horses; 2 corps of engineers, with 1500 men and 295 horses; and 3901 men of the gendarmerie. There are other military bodies, such as guards of the palace, invalids, &c., bringing up the total to 45,273 men. The army consisted of 4 artillery and 4 steam frigates, 4 corvettes, 3 brigantines, 1 brig, 10 steam-boats, &c., in all 40 vessels of war, with 900 guns. The population, including the continental possessions, with Sardinia and Cags, was, in 1848, 4,916,084. Spain had 75,017 infantry troops; 18,894 cavalry, with 7993 horses; 10,635 artillerymen, with 1870 horses; 2786 engineers; 10,717 gendarmerie, with 2000 horses; and
303 provincial guards in the Canaries; a total of 119,629 men, with 11,980 horses. There is also a corps of carabiniers consisting of 75 companies, of which 11 are cavalry, which form the frontier guard. There are likewise a consider- 
sible number of forces in Cuba, and other foreign posses-
sessions. The navy consists of 31 sailing ships, and 49 steam-vessels; there were 3 ships of the line, 10 frigates, ranging from 42 guns to 2 guns; 5 corvettes, 11 brigantines, &c., besides 110 gun-boats, &c. There are also a large number of gun-boats, &c. The total number of men on board the ship was 15,177. The population of Spain in 1856-7 was nearly 17,000,000.

In Sweden the military force is somewhat smaller. A part of the army is in barracks, and has been for six years, while another part (called Indelta) are cantonised in different places, and are paid by the owners of estates, and partly by the crown; having also a house and some ground furnished to each man; during war they are paid wholly by the crown, and in peace they are assembled once a year for four weeks to be exercised and reviewed; a third part consists of the militia of Othland, who are only available for home service; and the fourth part consists of the troops raised by conscription, to which every Swede between 30 and 55 years of age is liable. The total force thus composed amounted to 144,013 men. The enrolled troops form 3 regiments of infantry, 2 of cavalry, and 3 of artillery, and number altogether 7625 men, exclusive of officers; the canton troops number 6036 in their past, and 1202 in the present state; the 7625 men; and the troops raised by conscription number 95,295 men. Norway had a military force of 11,924 men, 1070 cavalry, 1330 artillery, with 9160 of the landwehr, 226 navy vessels of various sizes; it had 10 vessels of the line, 6 frigates, 3 corvettes, &c.; but its greatest strength consisted of a swarm of gun-boats and vessels of a similar character, there being 694 row-boats, besides 77 shallop, and 125 yaws carrying guns. The navy of Norway consisted of 11 vessels, mounting 450 cannon; of these 3 were frigates, 4 corvettes, 125 gun-boats, &c. The maritime conscription amounted to 46,000 men. The united population of Sweden and Norway in 1855 was 5,076,000. Switzerland the army consisted of 106,000 men, of whom 76,000 formed the regular army, and 32,000 the reserve. The regular army comprised 74 battalions of infantry, 45 companies of riflemen, 39 companies of cavalry, 40 companies of artillery, and 9 companies of engineers. The population of Switzerland in 1850 was 1,417,754.

Turkey had an army comprising 100,800 infantry, 17,250 cavalry, 7800 artillery, with 5200 additional in fortresses, 1600 engineers, 16,000 detached troops in Candia, Tripoli, and other places, 16,500 men to be raised, and 3000 men of the reserve of 128,880 men. The navy in 1853 comprised 70 vessels, manned with 34,000 seamen, and 4000 marines. The population of Turkey in 1854 (the latest total) was 26,680,000. Switzerland had on the peace establishment, 6149 infantry troops, 1729 cavalry, and 1562 artillery, engineers, &c., making a total of 9683 men; on a war establishment these can be raised to 22,018. The population of Wurttemberg in 1855 was 1,603,729.

The United States of America possessed an army composed of 1 corps of engineers, 5 regiments of cavalry, 4 regiments of artillery, and 10 regiments of infantry. The whole effective force was 15,526 men; but in addition, the militia amounted to 20,000 men. The navy consisted of 74 vessels, mounting 2944 guns. There were 10 sail of the line ranging from 130 to 84 guns; 13 frigates ranging from 50 to 50 guns, most of the guns of large calibre, and many of the vessels propelled by and of most excellent construction. The population of the United States in 1836 was 27,601,708.

MILITARY PUNISHMENTS. The policy which has been pursued of late years in modifying the punishments prescribed by the criminal codes has been extended to those which may be inflicted by courts martial for military offences. One material alteration consists in the limiting of corporal punishments; the utmost extent to which flogging can now be carried is 200 lashes. See Articles on MILITARY TRIBUNALS.

MILITIA. The qualifications of the officers of this constitutional force are now regulated by the Statute 18 & 19 Vict. c. 60. There have been of late years several statutes, modifying in other details the law relating to the militia, which it would appear, cannot serve out of the kingdom except with the consent of Parliament (18 & 19 Vict. c. 1).

MILLER, HUGH, an eminent geologist. He was born at Cromarty, in the north of Scotland, on the 12th of Octo-
ber, 1809. He was descended from a humble family, who had been long known in the parish of Cromarty as sailors. His father became eventually possessed of a small vessel of which he lost his life, and in which he was yet a child. In a work entitled 'My Schools and Schoolmasters, or the Story of my Education,' he has given not only an interesting account of his own life, but that of his father, and many of the members of his family. He received his first education at the parish school, and was distinguished for his fondness for poetry and poetical composition. At this time he was a large reader, and placed under contribution the libraries of the parish. In this way he laid the foundation of an extended knowledge of literature, which availed him in after life. But the most important part of his education consisted in the natural history instruction he received from an uncle who had acquired a taste for the observation of natural phenomena. Whatever might have been his aspirations, he was obliged to content himself with learning the trade of a master. This occupation however unexpectedly fostered the taste he had acquired for the study of natural history; and whilst hewing blocks of stone in the quarry, he was diligently studying the traces they exhibited of the animal life in which he indulged himself; and finally he became the historian of the Old Red-Stonebed, amongst the rocks of which he principally worked. His first literary efforts were not however directed to geology. He devoted himself to the mass, and was induced, by the refusal of a schoolmaster to publish, to devote his powers to the composition of a work to which has since been applied the name of 'Inverness Courier.' His first distinct prose publication was entitled 'Scenes and Legends of the North of Scotland.' Although the subject of this work was only of local interest, the purity of its style and the thought and feeling thrown into the subject discussed, made it a popular work, and several editions have been printed.

With naturally strong feelings, and a power of writing rapidly and impressively, it might be expected that a man in Mr. Miller's position would enter into the great discus-ion which terminated in a rupture of the Scotch church. His subject was one of vital importance to the Scotch people in the right. Lord Brougham and Vaux, on the opinions expressed by his lordship in the 'Auchterarder case.' This letter, which was referred to by Dr. Gladstone in his 'Church Principles, as the 'elegant and masculine production of C. H.' was published in a series of papers in the 'Witness.' These papers excited the surprise and admiration of the geologists who assembled at the first meeting of the British Association in Edinburgh in 1834. Sir Charles Lyell, Sir Roderick Murchison, and Dr. Buckland, were amongst the first to express their astonishment at the amount of new matter which was thus for the first time brought before them. Professor Agassiz, who was also present at this meeting, named one of the volumes 'as the most valuable description of the United States.' Mr. Miller, after its discovery. These papers were afterwards published in a volume, 'The Old Red Sandstone, or New Walks in an Old Field.' This work is written in a style remarkably clear, and treated of the subject in a peculiarly attractive manner. It has had a very large sale, and still remains one of the most popular works on geology in the English language. Its scientific merit consists in the description of a number of new fossil forms of animals belonging to a formation which had, up to the time of its pub-

3 G 2
sensitive to touch, but not so much so as the following species.

**M. pedicosa** has a prickly herbaceous stem, with petioles and peduncles more or less beset with stiff hairs or bristles; leaves somewhat digitately pinnate, with 4 pinnae, each pinna bearing many pairs of linear leaflets. It is a native of Brazil, as are several other species of Mimosa under the name of Sensitive Plant, the leaves falling on the slightest touch. The roots of this plant and its allies emit a most offensive smell, resembling the odour of a sewer at the time of impending rain. The leaves of *M. sepomans*, according to Willd., form a considerable article of commerce in India on account of their saponeous qualities. **Saponeous Plants.**

**MIMOMITIC ACID.** (Chemistry. S. 2.)

**MIMOSA** is a genus of Plants belonging to the natural order Scrophulariaceae. It has a tubular calyx, 5-angled and 5-toothed; corolla ringed, upper lip 2-lobed, lower one trifid, usually bigibbous at the base, segments all flat; stamens 4, didynamous, inclosed; cells of anthers diverging or divergent, at length subcordate; stigma bilaminar, capsule hardly furrowed, 5-valved, valves entire with flat margins, dissepiment at length free; placenta adnate. The species are erect or procumbent, glabrous, rarely villose, herbs, with usually tetragonal stems; leaves opposite, usually toothed. They are distributed in a large and varied area of South America, genus of the tribe, Fabaceae, pedicellate, superior ones sometimes racemose.

**M. latens.** Yellow-Flowered Monkey Flower, has leaves closely toothed, lower ones on long petioles, ovate or some-

what heart shaped, stem with calyx ovate, but campylnulate in the fructiferous state, with ovate-acute teeth, the upper tooth larger. It is a native of Chili. Babington says it has become naturalised in Great Britain. The corolla is yellow, with a dark mark in the middle.

**M. moschatus.** Musk-Scented Monkey-Flower, has diffuse stems clothed with woolly villi; leaves petiolate, ovate or ovate-lanceolate, a little toothed, rounded at the base, rather acute at the apex, and somewhat clammy; calyx tubular, but oblanceolate in the fruit; petal usually with 6 in number, which are either entire or divided, the inner row containing 6 or 8 entire segments; antheriferous stamens 6 or 8, opposite the inner segments of the corolla, alternated with stamens, and 4 or 5 in number; ovary united, 2-celled; berries 4-seeded from abortion. The species are common in marshes, with alternate quite-entire glabrous coriaceous leaves, and axillary fascicles of 1-flowered pedicels. The flowers are small and yellow. The plant is diffuse, rooting at the base.

**Mimus.** [Mocking Bird.]

**Mimusops**, a genus of Plants belonging to the natural order Sapotoceae. It has a calyx 6- to 8-parted; segments disposed in a twin order; corolla with a double row of segments, 6 in number, which are either entire or divided, the inner row containing 6 or 8 entire segments; antheriferous stamens 6 or 8, opposite the inner segments of the corolla, alternated with stamens, and 4 or 5 in number; ovary united, 2-celled; berries 4-seeded from abortion. The species are common in marshes, with alternate quite-entire glabrous coriaceous leaves, and axillary fascicles of 1-flowered pedicels. The flowers are small and yellow. The fruit is edible.

**M. elonga** has ovate-lanceolate or oblong leaves, acuminate, glabrous; pedicels many together, shorter than the petals, which are glabrous. It is a native of the East Indies, where it is much planted on account of its fragrant flowers, which come out chiefly in the hot season. A fragrant water is distilled from the flowers. The seeds yield an abundance of oil in request for painters. The leaves are said to produce an extraordinary noise when burnt.

**M. kaki** has obovate leaves, very blunt, silvery or hairy beneath, and acuminate at the apex; leaves numerous times as long as the petals, coiled at the ends of the branches; flowers fascicled, hexandrous. It is a native of the East Indies and Australia within the tropic. The tree yields a gum, and the fruit has a sweetish taste, and is much eaten by the natives of India.

**Minahead. [Some Perturbation.]

**Mineralogy.** According to the definition given by Kirwan, is the art of distinguishing mineral substances from each other. It may be regarded both as a science and an art. It is the art of distinguishing mineral substances, and the science for supplying accurate descriptions of minerals, and forming what may be termed a natural classification; and an art in reference to the arrangement of the descriptive characters for the purpose of afterwards distinguishing minerals from each other. Mineralogy then must be considered as including the
chemical composition of bodies, and an account of their external or physical properties. Both are requisite, for substances occur which agree in their chemical composition, and exhibit differences in their external characters; while there are other bodies which differ in their chemical constitution, but agree in their external properties.

Various methods of arrangement of minerals have been proposed by different authors. According to Werner, minerals were divided into the four classes of earthy minerals, saline minerals, inflammables, and metals; Karsten classed them under the heads of earths, salts, combustibles, and metals; Haly divided minerals into acidiferous earthy substances, earthy substances, non-metallic combustible bodies, metallic bodies, substances not sufficiently known to admit of classification, rocks, and volcanic products. In Phillips's 'Elements of Mineralogy,' the classes are earthy minerals, acidiferous earthy minerals, acids, acidiferous earthy minerals, acidiferous alkaline minerals, native metals, metalliciferous minerals, and combustible minerals. Berzelius attempted a strictly chemical classification of minerals: he has, however, candidly admitted that considerable difficulties attend this method, owing, in part, at least, to the uncertainty which exists as to what are the essential and what the accidental constituents of a mineral.

The following is the arrangement of Dufrenoy, as given in Professor Ansted's 'Elementary Course of Geology,' &c: —

Class I.—Simple bodies, or Binary Compounds never bases, generally essential ingredients in combinations, and serving as proximate elements.

2. Carbon. 5. Selenium.
3. Silicon.

Class II.—Alkaline Salts.

2. Salts of Potash.

Class III.—Alkaline Earths, and Earths.

Group 1. Salts of Barytes. 4. Salts of Magnesia.
2. Salts of Strontia. 5. Salts of Yttria.

Class IV.—Silicates.

Group 1. Anhydrous Aluminous Silicates.
2. Hydrous Aluminous Silicates.
3. Silicates of Alumina and Lime, or their isomorphs.
4. Aluminous and Alkaline Silicates, and their isomorphs.
5. Hydrous Aluminous Silicates with Alkaline and Lime bases, and their isomorphs.
   a. With Lime as a base.
   b. With Zircon as a base.
   c. With several bases.
7. Silico-Aluminates.
8. Silico-Fluorates.
10. Silico-Titanates.
11. Silico-Sulphurates.

Class V.—Metals.

11. Arsenic. 27. Gold.
13. Titanium. 29. Iridium.

Dana, in his useful 'Manual of Mineralogy,' adopts the following classification: —

Class I.—Gases; consisting of or containing Nitrogen or Hydrogen.
Class II.—Water.
Class III.—Carbon, and Compounds of Carbon.
Class IV.—Sulphur.
Class V.—Haloid Minerals: Compounds of the Alkalies and Earths with the Soluble Acids, or of their Metals with Chlorine or Fritone.

1. Salts of Ammonia. 5. Salts of Strontia.

Class VI.—Earthly Minerals: Silica and Siliceous or Aluminous Compounds of the Alkalies and Earths.

1. Silica. 5. Glucina.
3. Magnesia. 7. Thoria.
4. Alumina.

Class VII.—Metals and Metallic Ores.

We have already observed that Mineralogy includes a knowledge of the chemical composition and of the external and physical properties of minerals, and they are all divisible into two great classes of crystallised and uncrystallised. With respect to the merely crystallised minerals, we refer for an account of their forms to what is stated under Crystallography. There are some substances which do not assume regular forms, but have an imperfect crystalline structure; while those bodies which are not either crystallised or crystalline, unless they are pulverulent, are described as massive, and these are subdivided into such as possess particular forms, as botryoidal, mammellated, nodular, stalactitic, reniform, globular, and amorphous, or without any particular form.

The structure of minerals is an important feature. It may be Columnar, Lamellar, or Granular. The following are explanations of the terms used in describing the different kinds of columnar structure: —

Fibrous: when the columns are minute and lie in the same direction, as gypsum and asbestos. Fibrous minerals very commonly have a silky lustre; a fibrous variety of gypsum, and one of calc-spar have thin lustre very strongly, and each is often called satin-spar. Reticulated: when the fibres, or columns, cross in various directions, and produce an appearance having some resemblance to a net. Stellated: when they radiate from a centre in all directions, and produce a star-like appearance. Stiblite and gypsum are examples.

Radiated divergent: when the crystals radiate from a centre without producing stellar forms. Examples, quartz, gray antimony.

In the Lamellar Structure the laminae or leaves may be thick, or very thick; they sometimes separate easily, and sometimes with great difficulty. When the laminae are thin and separate easily, the structure is said to be Foliacceous. Mica is a striking example, and the term Micaceous is often used to describe this structure. When the laminae are thick, the term Tabular is often applied; quartz and heavy spar afford examples. The laminae may be elastic, as in mica, flexible, as in talc, or graphite, or brittle, as in diaspore. Small laminae are sometimes arranged in stellar shapes; this occurs in mica.

When the grains in the texture of a mineral are coarse, it is said to be Coarsely Granular, as in granular marble; when fine, Finely Granular, as in granular quartz; and if no grains can be detected by the eye, the structure is described as Impalpable, as in chalcedony. Granular minerals, when easily crumbled by the finger, are said to be Frangible.

Massive minerals also take certain imitative shapes, not peculiar to the regular varieties of structures. The following terms are used in describing imitative forms: —

Globular: when the shape is spherical or nearly so: the structure may be Columnar and Radiating, or it may be Concentric, consisting of coats like an onion. When they are attached, they are called Implantated Globules.
Reniform: kidney-shaped. In structure, they are like globular shapes.

Botryoidal: when a surface consists of a group of rounded prominences. The prominences or globules usually consist of fibres radiating from the centre.

Mammillar: resembling the botryoidal, but consisting of larger prominences.

Bread-crust: thread.

Acicular: slender like a needle.

Stalactite: having the form of a cylinder or cone hanging from the roofs of cavities or caves. The term stalactite is usually restricted to the cylinders of carbonate of lime hanging from the roofs of caverns; but other minerals are said to have a stalactitic form when resembling these in their general shape and origin. Chalcedony and brown iron-ore are often stalactitic.

Boiled-up: net-like.

Drusy: a surface is said to be drusy when covered with minute crystals.

Amorphous: shapeless: having no regular structure or form, either crystalline or imperfect.

Crystals are also called Pseudomorphous. A pseudomorphous crystal is one that has a form which is foreign to the species to which the substance belongs.

Crystals sometimes undergo a change of composition from aqueous or some other agency, without losing their form; for example, calcite may under certain conditions of temperature and pressure change to stilbite, still retaining the octahedral form. Cubes of pyrites are changed to red or brown iron-ore.

Again, crystals are sometimes removed entirely, and at the same time a chemical change occurs, another mineral is substituted; for example, when cubes of fluorspar are transformed to quartz. The petrifaction of wood is of the same kind.

Again, cavities left empty by a decomposed crystal are filled by another species by infiltration, and the new mineral takes on the external form of the original mineral, as a fused metal the form of the mould into which it is cast.

Again, crystals are sometimes incrusted over by other minerals, as cubes of fluorspar by quartz; and when the fluorspar is afterwards dissolved away, as sometimes happens, hollow cubes of quartz are left.

The first kind of Pseudomorphs are Pseudomorphs by Alteration; the second, Pseudomorphs by Replacement; the third, Pseudomorphs by Infiltration; the fourth, Pseudomorphs by Incrustation.

Pseudomorphous crystals are distinguished by having a different structure and cleavage from that of the mineral limited in form, and a different hardness, and usually little lustre.

A large number of minerals have been met with as pseudomorphs. The causes of such changes have operated very slowly, and are of great importance in determining the results.

The characters of minerals depending on light are also arranged. They are of five kinds, and arise from the power of minerals to reflect, transmit, or emit light. They are as follows:—1, Lustre; 2, Colour; 3, Diaphaneity; 4, Refraction; 5, Phosphorescence.

The lustre of minerals depends on the nature of their surfaces, which causes more or less light to be reflected. There are different degrees of intensity of lustre, and also different kinds of lustre.

The kinds of lustre are six, and are named from some familiar object or class of objects:—

Metallic: the usual Lustre of metals. Imperfect metallic lustre is expressed by the term Sub-Metallic.

Vitreous: the lustre of broken glass. An imperfect vitreous lustre is termed Sub-Vitreous. Both the vitreous and sub-vitreous lustres are common. Quartz possesses the former in an eminent degree; calcareous spar often the latter. This lustre may be exhibited by minerals of any colour.

Resinous: lustre of the yellow resins. Opal and sinterblende are examples.

Pearly: like pearl. Talc, native magnesia, stilbite, &c., are considered as pearly. It is exhibited with sub-metallic lustre, the term Metallic-Pearly is applied.

Silky: like silk; it is the result of a fibrous structure. Fibrous carbonate of lime, fibrous gypsum, and many fibrous minerals, especially those which in other forms have a pearly lustre, are examples.

Adamantine: the lustre of the diamond. When sub-

metallic, it is termed Metallic-Adamasin. Varieties of white lead-ore are examples.

The degrees of intensity are denominated as follows:—

Strong: when the surface reflects light with great brilliancy, and gives well defined images. Illa iron-ore, tin-ore, some specimens of quartz and pyrites are examples.

Miling: when an image is produced, but not a well-defined one. Granular spar, and celestine are examples.

Glistening: when there is a general reflection from the surface, but no image. Talc and copper-pyrites are examples.

Glimmering: when the reflection is very imperfect, and appears as if from points scattered over the surface. Flint and chalcedony are examples.

A mineral is said to be Dull when there is a total absence of lustre, as chalk.

In disintegrating minerals, both the external colour and the colour of a surface that has been rubbed or scratched, are observed. The latter is called the Streak, and the powder abraded, the Streak-Powder.

The colours are either metallic or non-metallic. The Metallic are named after some familiar metal, as copper-ore, bronze-yellow, brass-yellow, gold-yellow, steel-gray, lead-gray, iron-gray.

The Non-Metallic colours used in characterising minerals, are various shades of white, gray, black, blue, green, yellow, red, orange, purple, burgundy.

There are thus snow-white, reddish-white, greenish-white, milky-white, yellowish-white; bluish-gray, smoke-gray, greenish-gray, pearl-gray, ash-gray; velvet-black, greenish-black, black, blue-black; azure-blue, violet-blue, sky-blue, indigo-blue; emerald-green, olive-green, oil-green, grass-green, grass-apple, blackish-green, pistachio-green (yellowish); sulphur-yellow, straw-yellow, wax-yellow, ochre-yellow, honey-yellow, orange-yellow; scarlet-red, blood-red, flesh-red, brick-red, hyacinth-red, rose-red, scarlet, hair-brown, red-brown, reddish-brown, chestnut-brown, yellowish-brown, pinchbeck-brown, wood-brown.

The expression a Play of Colours is used when several prismatic colours appear in rapid succession on turning the mineral. The diamond is a striking example; also precious opal.

Change of Colours: when the colours change slowly or in different positions, as in labradorite.

Opalescence: when there is a milky or pearly reflection from the interior of a specimen, as in some opals, and in cat’s eye.

Iridescence: when prismatic colours are seen within a crystal; it is the effect of fracture, and is common in quartzes.

Tarnish: when the surface-colours differ from the interior; it is the result of exposure. The tarnish is described as friezed, when it has the hues of the rainbow. It is also called Labradorescent, from some prismatic crystals, of presenting a different colour in different directions.

The term Dichroism has been generally used, and implies different colours in two directions, as in the mineral loilit, which has been named dichroite because of the different colours presented by the bases and sides of the prism. Mica is another example of the same. The more general term has been introduced, because a different shade of colour has been observed in more than two different directions.

These different colours are observed only in crystals with unequal axes. The colours are the same in the direction of equal axes, and often unlike in the direction of unequal axes. This is the general principle at the basis of polychroism.

Diaphaneity: the property which many objects possess of transmitting light; or in other words, of permitting more or less light to pass through them. This property is often called transparency, but it is properly one of the degrees of diaphaneity. The following terms are used to express the different degrees of this property:—

Breached: is said to be transparent when the outlines of objects, viewed through it, are distinct. Glass and crystals of quartz are examples.

Sub-Transparent, or Semi-Transparent: when objects are seen through it, but the outlines of objects are indistinct.

Translucent: when light is transmitted, but objects are not seen. Lace-sugar is a good example; also Carnal marble.

Sub-Translucent: when merely the edges transmit light faintly. When no light is transmitted, the mineral is described as opaque.
Those minerals whose faces emit light exhibit two sets of phenomena, Refraction and Polarisation.

The index of refraction has been obtained for many minerals, of which the following are a few:

- **Air**: 1.000  
- **Calcite**: 1.654  
- **Spinel**: 1.764  
- **Sapphire**: 1.794  
- **Garnet**: 1.815  
- **Zircon**: 1.961  
- **Blende**: 2.260  
- **Diamond**: 2.420  
- **Chlorite**: 2.974

Many crystals possess the property of refracting light in two directions instead of one, and objects seen through them consequently appear double. This is called Double Refraction. It is most conveniently exhibited with a crystal of calcite. A thin sheet, cut in a particular way, of this mineral from Iceland, called from the locality Iceland-Spar, is used. On drawing a line on paper and placing the crystal over it, two lines are seen instead of one—one by ordinary refraction, the other by an extraordinary refraction. If the crystal, as it lies over the line, be turned around, when it is in one position the two lines will come together. Instead of a line make a dot on the paper, and place the crystal over the dot: the two dots seen will not come together on revolving the crystal, but will seem to revolve one around the other.

The extraordinary ray, which is the ray in every direction except that of the vertical axis, and this direction is called the Axis of Double Refraction. To view it in this direction the ends must be ground and polished. The diverse nature of the two rays is shown by the way in which the species of the two rays are equal (the dimetric and hexagonal systems) have one axis of double refraction; and those in which they are unequal (the trigonometric, monoclinic, and triclinic systems), have two axes of double refraction.

Red rays in the latter are rays of extraordinary refraction. In nitre the two axes are inclined about 5° to each other; in arragonite 18° 18'; in topaz 65°. The positions of the axes thus vary widely in different minerals.

The extraordinary ray exhibits peculiar properties of light, termed Polarisation. Viewed by means of another doubly-refracting crystal, or crystalline plate (called from this use of it an analysing plate), the ray of light becomes a single ray, but with the property of vibrating. If the polarised light is made to pass through a crystal possessed of double refraction, and then be viewed in the manner stated, rings of prismatic colours are developed, and on revolving the analysing plate the coloured rings and intervening dark rings successively change places.

Several minerals give out light either by friction or when gently heated. This property of emitting light is called Phosphorescence.

Two pieces of white sugar rubbed against one another give a feeble light, which may be seen in a dark place. The same effect is obtained on striking together fragments of quartz, and even the passing of a feather rapidly over some specimens of silex-blene is sufficient to elicit light.

Floor-spar is the most convenient mineral for showing Phosphorescence by Heat. On powdering it, and throwing it on a shovelled heated nearly to redness, the whole takes on a bright glow. In some varieties the light is emerald-green; in others purple, rose, or orange. A massive floor from Herefordshire, Contamahet, shows beautifully the emerald-green phosphorescence.

Some kinds of white marble, treated in the same way, give out a bright yellow light.

After being heated for a while the mineral loses its phosphorescence, but a feeble electric shock will in many cases to some degree restore it again.

Many minerals become electrified on being rubbed, so that they will attract cotton and other light substances: and when electrified some exhibit positive and others negative electricity when brought near a delicately suspended magnetic needle. The diamond, whether polished or not, always exhibits positive electricity, while other gems become negatively electrified in the rough state, and positive only in the polish. Friction with a piece of cloth is sufficient to excite electricity in some varieties of stone. Some minerals thus electrified retain the power of electric attraction for many hours, as topaz, while others lose it in a few minutes.

Many minerals become electric when heated, and such species are said to be Pyro-Electric. If a prism of tourmaline, after being heated, be placed on a delicate frame, which turns on a pivot like a magnetic needle, on bringing the needle near it, one extremity will be attracted, the other repelled, thus indicating the polarity alluded to. Several other minerals exhibit electrical phenomena, especially beryllace and topaz, which, like tourmaline, are hemispherical in their modifications.

Magnesium is exhibited more especially in the ores of iron. The leadstone, as the magnetic oxide of iron is called, is common where the ores of iron are found. When mounted like a horse-shoe magnet, a good leadstone will lift a weight of many pounds. This is the only mineral that has decided magnetic attraction; but several ores containing iron are attracted by the magnet, or, when brought near a magnetic needle, will cause it to vibrate; and moreover, the metals nickel, cobalt, manganese, palladium, platinum, and osmiun, have been observed to be slightly magnetic. Minerals vary in their specific gravity. This must be ascertained as for any other substance. [Specific Gravity.]

The Hardness of minerals differs much, and is the point first attended to in mineralogists. In order to ascertain the hardness of a mineral it is only necessary to draw a file across the specimen, or to make trials of scratching one with another. As standards of comparison, the following minerals have been selected, increasing gradually in hardness from talc, which is very soft and easily cut with a knife, to the diamond which nothing will cut; this table is called the Scale of Hardness:

1. **Talc**: Common foliated variety.
2. **Rock-Salt**.
3. **Calcite-Spar**, transparent variety.
4. **Flour-Spar**, crystallised variety.
5. **Apatite**, transparent crystal.
6. **Felspar**, cleavable variety.
7. **Quartz**, transparent variety.
8. **Topaz**, transparent crystal.
9. **Sapphire**, cleavable variety.
10. **Diamond**.

If on drawing a file across a mineral it is impressed as easily as flour-spar, its hardness is said to be 4; if as easily as felspar, the hardness is said to be 6; if more easily than felspar, but with more difficulty than apatite, its hardness is described as 5 or 6.

The file should be run across the mineral three or four times, and care should be taken to make the trial on angles equally bent, and on parts of the specimen not altered by exposure. Trials should also be made by scratching the specimen under examination with the minerals in the above scale, as sometimes, owing to a loose aggregation of particles, the file wears down the specimen rapidly, although the particles are very hard.

Minerals differ in their state of aggregation. Solid minerals may be:

**Brittle** when parts of the mineral separate in powder on attempting to cut it.

**Sectile**: when thin pieces may be cut off with a knife, and the mineral pulverises under a hammer.

**Malleable**: when slices may be cut off, and these slices will flatten out under the hammer, as native gold and silver.

**Flexible**: when the mineral will bend, and remain bent after the bending force is removed, as talc.

**Elasitic**: when the bending it will spring back to its original position, as mica.

A liquid is said to be **Viscous** when oil pours it the drops lengthen and appearropy, as petroleum.

When a mineral is broken its cut surface presents different aspects. The following are the several kinds of fracture in minerals:

**Conchoidal**: when the mineral breaks with a curved or concave and convex surface of fracture. Flint is a good example.
Even when the surface of fracture is nearly or quite flat. Uneven when the surface of fracture is rough with numerous small elevations and depressions. For when the elevations are sharp or jagged, as in broken iron. Soluble minerals may have taste : the kinds are— Astringent: the taste of vitriol. Sweetish-astringent: the taste of alum. Bitter: the taste of Epsom salts. Sour: the taste of sulphuric acid. Excepiing a few gases and soluble minerals, minerals in the dry unchanged state do not give off odour. By friction, moistening with the breath, the action of acids, and the blow-pipe, odours are sometimes obtained, which are thus described by,— Allaceous: the odour of garlic. It is the odour of burning arsenic, and is obtained by friction and more distinctly by means of the blow-pipe from several arsenical ores. Horse-Radish odour: the odour of decaying horse-radish. It is the odour of burning selenium, and is strongly perceived when ores of this metal are heated before the blow-pipe. Sulphurous: odour of burning sulphur. Friction will elicit odours, and by heating with sulphuric acid. Fetid: the odour of rotten eggs or sulphuretted hydrogen. It is elicited by friction from some varieties of quartz and limestone. Argillaceous, the odour of moistened clay. It is given off by limestone and some allied minerals when breathed upon. Others, as pyrrhotite, afford it when heated. Without submitting the mineral to a regular analysis, advantage is often taken of the effects of heat by means of the blow-pipe, with or without the aid of certain fluxes, as soda, phosphoric salt, &c.; and the mineral is stated to be either fusible alone, or with the assistance of the different fluxes, and the nature of the resulting compound is described; sometimes it is a colourless glass, at other times coloured, translucent, &c. (Blow-pipe.)

MINNESOTA, a Territory of the United States of North America, lies between 43° 30' and 49° 22' N. lat., 90° 0' and 109° 30' W. long. It is bounded E. by the State of Wisconsin, N. by the British North America, W. by the Territory of Nebraska, and S. by the State of Iowa. The area is 141,639 square miles. The population in 1856 was estimated at 160,000.

The Territory has generally the character of an immense high "rolling prairie land," but there are considerable exceptions. Towards the eastern side it rises into a ridge of lofty hills, which traverses a large portion of it in a north-east and south-west direction. From a short distance above the Falls of St. Anthony, on the Mississippi, there extends southward a vast forest region for 120 miles, with a breadth ranging from 15 to 40 miles. The northern and north-eastern portion of the Territory is sometimes termed the "region of lakes," from the great number of lakes of various sizes which here lie along the upper course of the Mississippi and its tributaries; and for some distance below this region the Mississippi traverses a swampy country.

The Territory is in every part abundantly watered. The Mississippi rises within its boundaries on Lake Itasca, and belongs wholly to it down to the confluence of the St. Croix, after which, to the southern boundary of the territory, it belongs equally to Minnesota and Wisconsin. This part of its course is described under Mississippi River. The principal tributaries which join it in this territory are the St. Croix, which separates Minnesota from Wisconsin, and the Mississippi, a large and broad stream, which rises near the centre of the Territory, flows through Big Stone Lake, and after a course of winding its windings of some 500 miles, first south-east, then south, and finally north-east, falls into the Mississippi at Fort Snelling. The Mississippi is navigable in Minnesota by steam-boats during seven months of the year; the other five months it is, with its tributaries, closed ice. The Missouri, with its tributary, the White River, forms the western boundary of Minnesota; it is navigable by steam-boats throughout Minnesota. It is joined by several small feeders, but none of any consequence in this Territory. The Red River, which flows northward through the region of lakes in Minnesota, and is the source in, and belongs for a very considerable distance to Minnesota, and has numerous tributaries in this part of its course. The Big Sioux and several other rivers have also their upper courses in this Territory. The Mississippi, Missouri, and the main streams of the St. Croix and the Red River afford great commercial facilities: while the numerous smaller streams and lakes afford like facilities for agricultural and manufacturing operations. The principal lakes are the Iowa, Lake Pepin, Lake Itasca, Lake Pepin, Lake Utica, and Lake Pepin, which range from about 5 to 20 miles long.

As regards its geological character, the larger half of the country, including the centre and north-eastern portions, appears to belong to the igneous and metamorphic formations. In the northern and south-eastern districts, are tracts of Lower Silurian rocks. Extending from the centre eastward to Lake Superior is a narrow band of New Red Sandstone, with dykes of copper trap. The Missouri and Big Sioux in Minnesota traverses the flow or breccia rocks, which are bordered on the east by tertiary formations. Copper- and lead-ores are said to have been found.

The climate, though severe, is not subject to rapid or extreme variations. The winters are long but owing to the dryness of the air during winter, the coldest weather is endurable. A great quantity of snow falls in the winter, but generally there is not much moisture. The soil over a country so vast in extent, and having such different lithological features, is necessarily varied but; in the parts where it is known to be remarkably fertile, and the mould is of unusual depth. Most of the cereals appear to flourish: maize, oats, and wheat are the crops most cultivated, but rice, barley, and buckwheat are also grown. Potatoes, peas, and beans are raised to some extent. The broad prairies appear well adapted for raising stock. There are at present no manufactories in the Territory. The chief occupation is the cutting and preparing of pine lumber, much of which is returned to home consumption, but the larger portion is sent to St. Louis.

At the census of 1850 Minnesota was divided into nine counties. The political capital is St. Paul, the only place which can as yet fairly take rank as a town; but Pembina on the right bank of the Red River and the seat of the Roman Catholic parish, is important.

St. Paul, the capital, occupies a commanding position on the left bank of the Mississippi, 15 miles below the Falls of St. Anthony, in 44° 23' N. lat., 93° 4' W. long. The first trading house was built here in 1824, it having previously been the station of one of the French voyageurs.

It now contains a state-house 139 feet long, a court-house, jail, nine churches, schools, numerous hotels, stores, an inn, foundry, agricultural implement factories, flour-mills, &c. The streets are traversed by coaches and omnibuses; but, whilst the river is free from ice, steam-vessels arrive and sail daily, although the vicinity of the town is still a wilderness. In 1850 St. Paul had 1135 inhabitants; in the spring of 1853 it is said to have had above 2500.

Minnesota has a legislature, consisting of a Council and House of Representatives. By the constitution, as framed by the territorial legislature, citizenship is not limited to whites, but extended to "all persons of a mixture of white and Indian blood who shall have adopted the habits and customs of civilized life." Minnesota was erected into a Territory by Act of Congress in March 1849; that portion of it west of the Mississippi having previously formed a part of the Territory of Iowa, and that part east of the Mississippi having belonged to the Territory of Wisconsin.

On the 26th of February, 1857, an Act was passed by Congress, authorising Minnesota to form a State government. This Act makes an alteration in the area of Minnesota, and consequently in the population. The Convention for forming the constitution of Minnesota was appointed; but the particulars have not yet (April 1, 1858), reached us.

(Statistical Gazetteer of the United States; Seventh Census of the United States; American Almanac, 1854; Own Resolution of a Geological Survey of Wisconsin, Iowa, and Minnesota; Maroon, &c.)
MIRIAMICH. [NEW BRUNSWICK.]

MIRBEL, BRISSEAU- C.F., a French naturalist, more especially distinguished for his knowledge of botany. He was born on the 27th of March 1776. He was appointed professor of botany in Paris in 1801, and one of his earliest published works was the lecture introductory to the Inductive Method of Planting, in which he expounded the natural history of Buffon. In this work, which extended to eighteen volumes, the first, second, fourth, fifth, and sixth, were written by Mirbel. In 1802 he published his treatise 'On Vegetable Physiology.' He was also associated with Lamartine in the publication of the 'Nouvelles Edis de la Plante,' in which he not only described the general structure of the plant, but the history of the development of its embryo. In his general theoretical views and numerous exact observations, Mirbel exercised a great influence on the progress of the science of botany in the first half of the 19th century. He died September 12, 1854.

MITCHELL, SIR THOMAS LIVINGSTONE, Knor., was born in 1792, at the residence of his father, John Mitchell, Esq., of Craigmillar, in the county of Edinburgh, Scotland. The name of Livingstone was assumed by the family on a marriage with the heiress of J. Livingstone, Esq., of Haining, brother to Lord Viscount Kilsyth, who was attainted in 1716. Thomas Livingstone Mitchell entered the British army in Portugal in 1808, and served on the staff till the termination of the Peninsular War, when he had attained the rank of major. In the course of this service he had distinguished himself so much as to attract the attention of the late Sir George Murray, upon whose recommendation he was sent back to the Peninsula to make surveys of the great battle-fields. The series of military maps which he constructed from these surveys are preserved in the Ordnance office, and are unsurpassed for accuracy and skilful execution. A map made by him of the battle of Talavera was 18 electoral votes for Lord Lincoln, of whom he is the Museum of the United Service, Whitehall. He married in 1818 the daughter of Lieutenant-General Blunt.

In 1857 Major Mitchell published 'Outlines of a System of Surveying for Geographical and Military Purposes,' 8vo, London. In 1859 he was elected deputy surveyor-general of New South Wales under Mr. Oxley, whom he succeeded as surveyor-general—an office which he retained till his death. Besides performing the ordinary duties of his important situation, he conducted four expeditions into the interior, and was one of the most successful of the explorers of the Australian continent. Three of these expeditions were performed in the years 1831-32, 1835, and 1836. The first was in search of an imaginary river, which was supposed to be resided among the aborigines, described as having a north-west course, and entering the sea; and the result of the journey was the discovery of the Peel River and the Namoi. The second expedition was for the purpose of exploring the country to the north of the Darling, and was conducted as the third expedition, when the Darling was traced to its junction with the river Murray. Australia Felix was also discovered, and the Glenelg was explored to its entrance into the sea. These expeditions were conceived and executed with great and occasional vigilance, combined with the steadiness and resolution of an experienced leader. Major Mitchell published in 1858 his account of these journeys, under the title of 'Three Expeditions into the Interior of Australia.' The work contains Descriptions of the recently-explored Region of Australia Felix, and of the present Colony of New South Wales, 2 vols. 8vo, London, illustrated with lithographic drawings and woodcuts. He had a short time previously published his 'Map of the Colony of New South Wales, compiled from actual Measurements with the Chain and Circumferencer, and according to a Triangonometrical Survey, in Three Sheets.' Major Mitchell came to England for the purpose of superintending these publications, and, before his return home in 1839, the honour of knighthood from the queen, and the title of D.C.L. from the University of Oxford. He was also elected a Fellow of the Royal Society and of the Geographical Society of New South Wales.

Sir Thomas Mitchell's fourth and last expedition was commenced in December 1845, and terminated in December 1846. His account of it was published in 1848, under the title of 'A Journal of an Expedition into the Interior of Australia.' At the mouth of the Gulf of Carpentaria, by Lieut.-Colonel Sir T. L. Mitchell,' 8vo, illustrated with lithographic engravings and maps. This expedition did not reach the Gulf of Carpentaria, having been compelled to return in consequence of the loss of the cattle and horses from drought and want of pastureage; but advancing as far as 21° 30' S. lat. Sir Thomas Mitchell himself was the first to discover the important river which he named the Victoria, and saw it taking a north-western course, in a direction towards the Gulf of Carpentaria. Mr. Kennedy, however, Sir T. Mitchell's assistant-surveyor, in a subsequent journey in 1847, found that the river makes a great bend to the south-west, and he traced its course in that direction as far as 26° 14' S. lat. The channels were in many places deep and swift, and he was compelled to return from want of water and pastureage for his horses. In 1850 Sir Thomas Mitchell published an admirable manual of geography for the schools of New South Wales, entitled 'Australian Geography, with the Shores of the Pacific and those of the Indian Ocean, designed for the use of schools,' 12mo, Sydney. In 1853 he again visited England. Having invented a new propeller for steam-vessels on the principle of the curious instrument used by the natives of Australia, he delivered a lecture on the subject which excited much interest. It was published under the title of 'Origin, History, and Description of the Boomerang Propeller, a Lecture delivered at the United Service Institution,' 8vo, London.

Sir Thomas Mitchell was advanced to the rank of colonel in 1854. He died October 6, 1855, at his residence near 12mo, Sydney, and his remains received the honour of a public funeral.

MITCHELTOWN, county of Cork, Ireland, a market and post-town, and the seat of a parish which is pleasantly situated near the river Funcheon on a small tributary, in 65° 17' N. lat., 8° 17' W. long., 30 miles N.N.E. from Cork, 129 miles S.W. by S. from Dublin. The population in 1851 was 3091. Mitcheltown Poor-Law Union comprises 9016 acres. Mitcheltown College is a national school, and a town library. There are also a court-house, fever hospital, dispensary, bridewell, and Union workhouse. Mitcheltown College, a group of neat buildings with a chapel attached, was founded by the Earl of Kingstown for the support of 12 males and 16 females of his decayed Protestant tenantry. Each receives 40l. a year, besides a house and garden. On one side of the square is the gateway to the extensive demesne of Mitcheltown, the seat of the representatives of the property, of which the village of Mitcheltown is a part. The river Funcheon rises, and joins with its towers and battlements forms a striking object. It was erected in 1833, and is the largest and finest of the modern castles in Ireland. Petty sessions are held monthly. Fairs are held January 10, March 25, May 22, July 30, September 19, and November 12. Mitcheltown and Kingstown caves are two series of beautiful stalactite caverns, under small limestone hills about 5 miles from Mitcheltown on the Dublin road. One series, discovered in 1835, is 870 feet in extreme length by 572 feet in breadth.

MITFORD, MARY RUSSELL, one of the most delightful of our female authors, was born on the 16th of December 1786, at Alresford, Hampshire. Her father was a physician, and had a large family, consisting of unthrifty and somewhat eccentric habits, and consequently unsuccessful alike in his professional pursuits and in his pecuniary affairs. By his general want of management and inju-
rialis, was her most important subsequent work in a single style. Her later sketches and essays furnished to various periodicals have not, we believe, been collected. Among her other works may be mentioned her 'Stories of Country Life.' She also for some years edited Finden's 'Tableaux;' and three volumes of 'Stories of American Life by American Authors.'

Whilst at the Chelsea school Miss Mitford's dramatic tastes had been as carefully nurtured as her poetic tastes. The consequence was that in early life her most ardent aspirations and efforts were directed towards the stage. She wrote altogether a large number of dramatic pieces of various kinds. Four of these were works of considerable importance. The first, 'Julian,' was performed in 1823, with Macready for the hero, and met with decided success. The 'Foscaris,' a tragedy, was produced in 1825, and another, 'The Gallows,' which had a run, in 1826. 'Charles the First' was not so fortunate as its predecessors; Colman, then licensor of plays, having refused to sanction its performance on the ground of the impropriety and danger of permitting the trial of an English king to be represented on the stage. Driven from the legitimate houses, Charles I. was at length brought out at a minor theatre, the Cobourg, and it has not apparently been repeated elsewhere. Besides these an opera, 'Salat and Kalaarade,' written by her, was produced at the Adelphi. Miss Mitford's last literary appearances was in an edition of her 'Dramatic Works' (3 vols., 1854), which, besides the pieces above named, included a tragedy—printed for the first time—'otto of the Forest,' and 'A Visit to the New World,' which was reprinted for performance, and twice withdrawn; a melodrama, 'Gaston de Blondeville;' and several 'Dramatic Scenes.'

In looking at Miss Mitford's works, it should be borne in mind that, though they seem almost invariably the relics of a mind full of happy images, and surrounded by pleasant circumstances, they were often really written under the pressure of pecuniary discomfort and during much ill-health. As long as her father lived her attention to him was entire, and from his death she devoted herself with all the firmness and energy which her fame is chiefly founded—'Our Village'—for a new edition, which appeared in 1853, she compiled a sort of literary patchwork, 'Recollections of My Literary Life; Books, Places, and People,' which is in fact a sort of compiling. But it is not the interest of such a work that had, she fancied, most influenced her mental career, with a somewhat large addition of extracts from her favorite authors. She also prepared the collected edition of her 'Scots Magazine,' and published an 'Unpublished Poems,' which were printed various editorial biographies; and in 1854 she published 'Atheron; a novel,' in 3 vols. She died at her residence, Swallowfield Cottage, near Reading, on the 10th of January 1855.

MOA. [Dinwiddie, S. 2.]

MOCHA-STONE. [Asatr]

MOIR, DAVID MACBETH, was born at Musselburgh, in the county of Edinburgh, on the 5th of January 1798. He was educated at the grammar-school there, and was apprenticed to a local printer and stationer.

...
which brought him little profit or fame. He was also a member of 'The Musselburgh Forum,' a debating society, in which he favourably distinguished himself. In 1817 he entered into business as a partner in his native town, with Dr. Brown, who had an extensive but laborious practice. Moir worked hard at his professional duties, but, when the toils of the day were ended, he employed a great part of the night in his literary pursuits. He was at this time a frequently determined author, and his name appeared in 'Blackwood's Magazine.' When 'Blackwood's Magazine' was started, he became a still more constant contributor to its pages. He wrote for it both prose and poetry, both comic and serious. Among his comic effusions were 'The Eve of St. Valentine's Day,' and 'The Antique Ring.' Some of them were supposed to be from the pen of Dr. Maginn. His serious poems were marked as by a, a signature which he retained in that magazine until his death. In 1823 he formed a strong friendship with John Galt, who, when he departed for America, left his novel, 'The Last of the Lairds,' unfinished, and Moir wrote the concluding chapters for him. In 1824 he published 'The Legend of Generoive, with other Tales and Poems,' consisting of selections from his magazine contributions, with some original additions. In the same year he commenced, in 'Blackwood's Magazine,' his novel of 'The Autobiography of Manse Vatch,' which was continued for nearly three years, and was afterwards published separately. It was greatly successful, and the character of its author was emboldened by some of the peculiarities of Scottish character. During all these literary labours he continued to attend to his professional duties with indefatigable assiduity and extreme kindness. In 1830 he married, and it is said he have slept a night out of Musselburgh. He was now recommended to remove to Edinburgh, where he might have readily attained a more lucrative practice, but his attachment to his old haunts and his old patients and neighbours caused him to refuse the offer of marriage. In 1831 he published his 'Outlines of the Ancient History of Medicine, being a View of the Healing Art among the Egyptians, Greeks, Romans, and Arabsians.' In 1832, after having exercised himself in the practice of his profession for twenty years, and while cholera was raging in his district, he published a pamphlet, 'Practical Observations on Malignant Cholera,' which had a very extensive circulation; and this was followed by 'Proofs of the Contagion of Malignant Cholera,' both works being allowed to possess great merit, even by those who differed from the author's conclusions. In 1832 Mr. Moir attended the meeting of the British Association for the Advancement of Science at Oxford, and afterwards visited London, where he extended his acquaintance amongst the literary worthies of the city. In 1833 he published 'Imagery Verses,' in which, among other things, he records, with much tenderness, the loss of two of his sons, who died young. In 1845 he contributed the account of the civil history and antiquities of the county of Edinburgh, which made him the chief town to the 'New Statistical Account of Scotland.' In 1846 he met with an accident, being thrown from a carriage, by which he was rendered lame for life. In the spring of 1851 he delivered a series of lectures on 'The Poetical Literature of the Past Century,' at the Edinburgh Philosophical Institution. In the same year, 'Selim,' his last contribution to 'Blackwood's Magazine,' appeared, and on the 6th of July he died. His activity had continued unabated during his whole life. He had, besides paying a sedentary attention to his profession, filled various municipal offices, and had been a member of the General Assembly. His contributions to 'Blackwood' alone number 370. His serious poetry, by which he will be chiefly remembered, is sweetly pensive and tender, without any markable original poetic power, but it possesses a charm in its natural imagery and its appeals to our feelings that can never fail to please. In 1862 his 'Poetical Works,' which, however, are only a selection, were published, with a memoir by W. M. Brand. 

MOLÉ, COMTE DE, was born in 1781, and was descended from an illustrious family in France. He was the son of the President M. lè, who fell a victim to the violence of the first French Revolution. He was however rescued from the wreck of his family fortunes to enable the father to send his son to the Central School of Public Works, afterwards called the Polytechnical, where he pursued his studies with industry and vigour. In 1800 he published 'Essais de Morale et de Politique,' which attracted the attention of the Emperor Napoleon I, and secured for him the post of auditor of the Council of State. These essays, as may be supposed, were received with a highly absolutist cast, and though the auditor continued to the last a staunch adherent of the Bourbon dynasty, he remained in office under the Bourbons after their restoration, who created him a peer of France. To the policy and measures of Prince Polignac he offered the most decided opposition. After the fall of the latter he was appointed by Louis Philippe to the portfolio of Foreign Affairs, and shortly afterwards was advanced to the post of Prime Minister of France, which he eventually resigned by the opposition of M. Guizot and M. Thiers. Under the Ministry of Thiers he was appointed to the Legislative Assembly, he took little or no part in its proceedings. The family of Count Molé was of that rank which is known as the" nobility of the robe," and his ancestors were of such blood as long ago as the days of Henri IV. Talents and administrative capacity seem to have been hereditary in the family, as well as the love of legal order, monarchy, and constitutional government. Count Molé was almost the last remaining link between his countrymen of the old and of the new régime, as combining the high-bred tone and monarchical principles of the former with a proportion of the liberal principles which are the distinctive mark of the latter class. While M. le Prince Molé accepted each successive change in the governing system of France, he recorded himself as one who could not say that he ever swerved from principle in the opinions which he had originally professed. At the close of his long career, under various successive changes of government, he retained the same attitude, and departed life as he entered upon it, a supporter of the old monarchy. In his theological opinions he inclined to the Ultramontane party, and from his high character, great abilities, and illustrious position, he was one of the strongest Catholic supporters of the Roman Church. His Memoirs, which naturally include reminiscences of all the great men and notables of France during the first half of the 19th century, were announced as in preparation, but the death of the author, who died 4th November, 1861, at his family seat at Chapmatreux, November 23rd 1855. MOLESWORTH, RIGHT HON. SIR WILLIAM, eighth Baronet of that name, was born in 1810. He was the lineal representative of an old Cornish family of large landed possessions, originally of Irish extraction. The first baronet was governor of Jamaica in the reign of Charles II. Sir William's father died in 1823. It is uncertain at what school Sir William Molesworth was first educated, but it is certain that he was spending some time at Cambridge, he was appointed in 1837 by the Government to Edinburgh as Professor of Political Economy, metaphysics, and metaphysical science, by an Italian refugee, and afterwards passed to a German university. In this latter soil his mind took deep root; he acquired the German language, and will with the French a talent in the study of languages. Having left England with an average acquaintance of general and classical knowledge, he concentrated his powers in Germany upon the study of philosophy and history. His mind however revolted against the mysticism of the German school, and as soon as he was released from collegiate study he made the usual tour of Europe. On his return to England in 1831 he was still in his minority. His first public appearance in this country was at a meeting convened in his native county in that year for the purpose of supporting parliamentary reform, and his speech on that occasion gave considerable promise of future eminence. He was little more than of age when he was returned to parliament unopposed in December 1832, for East Cornwall, by which constituency he was re-elected in December 1835, but withdrew from the contest in July 1837, when he was returned for Leeds. At the dissolution of 1841, being convinced that his chance of success at Leeds was hopeless, he declined the contest, and remained out of parliament for four years. During this time, which he spent in Germany and Italy, he engaged himself a sounder political education, and accumulated capital for his future senatorial life. In 1850, however, on the death of Mr. Wood, he offered himself as candidate for the representation of the borough of Huntingdon, and though strenuously assailed for his support of the grant to Maynooth College, he was successful, and he continued to represent the same constituency to his death. In January 1859 he accepted the office of First Commissioner of Public Works on the formation of Lord Aberdeen's administration,
and was re-elected without opposition; and again on his subsequent translation to the Colonial Office.

As a 'Commons' debater' Sir William Molesworth was not of the oratorical school of speakers in parlour life; but was always valuable, though of too philosophic a cast to be generally popular. Those on the colonies, delivered in 1838; in 1840 on the state of the nation and the condition of the people; on transportation, in 1837-38; and on many important questions in his time. The same passion and spirit were of great merit and immense practical utility. They were carefully prepared beforehand, and were the results of reading, labour, and reflection. In July 1855 Sir William Molesworth found a sphere far more congenial to his tastes, and here his admirers would hold him in esteem, on being appointed to the secretarship of the colonies, but he held that office only for the brief space of four months, when his career of public usefulness was cut short by death, which occurred on 1 April 1856. The colonial and domestic press were all but unanimous in expressing their satisfaction at his appointment; it was not forgotten that he had taken the deepest interest in the affairs of Canada and Australia, and had studied the country and mastered the theory of colonisation to a greater extent than perhaps any contemporary. Neither was it forgotten that he was the first person who, in this country, succeeded in calling public attention to the manifold abuses connected with the transportation of criminals, though eighteen years had elapsed since the passing of the hurriedly constructed and not entirely well-conceived anti-abolitionist act of 1833. It brought to light all the horrors of our penal system. In the words of a writer in the 'Times,' 'Sir William Molesworth found our colonial empire disorganised and disordered, and the Colonial Office was meddled with as it then was to a system of ignorant and impertinent interference. He first aroused the attention of parliament to the importance of our remote dependencies, and explained with incomparable clearness and force the principles of our self-government and independence. With unexampled vigour and great constructive power he prepared draught constitutions, and investigated the relations between the imperial government and its dependencies. Starting from a small mismanaged and public opinion over to the other side, till principles once considered as paradoxes came to be regarded as axioms. By such means he fairly won the position of Secretary of State for the Colonies; but he did not live to enjoy the prize which he had grasped. Before we had time to hear of the satisfaction with which his appointment was sure to be hailed by our remote dependencies, the sceptre was snatched from his hand by death, and the post became again vacant. In the full vigour of life and intellect, in the prime of life, he was at the height of his powers, and the noblest prize of ambition, in the enjoyment of the confidence of his sovereign and the esteem of his fellow-subjects, he was taken away suddenly and prematurely, yet not so soon as to deprive his friends of the consolation of thinking that he died when he was strong, and when he knew himself. He left his name with the destinies of every British community planted on the face of the earth. The best monument that could be raised to him would be a complete collection of his parliamentary speeches; the noblest epitaph that could be inscribed on his tomb would be the title of the 'Liberator and Regenerator of the Colonial Empire of Great Britain.'"

Though he had not avowedly appeared before the public as an author, Sir William Molesworth was favourably known in learned and scientific circles. As 'Westminster Review,' he for some years conducted it either alone or in conjunction with his friend, Mr. John Stuart Mill, the eminent political economist, and during that time he was a not infrequent contributor to its pages; he likewise wrote at different times many articles in other periodicals and newspapers. He also edited and published at his own expense a complete edition of the English works of the philosopher Hobbes, in 16 volumes. [Hobbes, Thomas.] He was a good mathematician and a well-known botanist; but his acquirements extended over a large range of subjects. In private life few men have been more highly esteemed.

MOLLUSCA. — According to the articles Conchifera, Gasteropoda, Cephalopoda, and Malacology, for information as to the zoological arrangement and subdivision of the various families of the Mollusca, we shall in the present article consider the animals which constitute this great group in a purely anatomical and morphological point of view; that is, we shall endeavour to show—firstly, what Common Plan or Archetype is discoverable among the varieties of Molluscan forms; secondly, in what way the Common Plan is more specially modified in the leading sub-generic groups of this great division of the animal kingdom; thirdly, the various modes in which the organs are arranged being thus comprehended—what peculiar characters are presented by these organs themselves; and fourthly, the development of the Mollusca, so far as it bears upon the idea of a Common Plan. 

1. The Common Plan or Archetype of the Mollusca.—By the Common Plan or Archetype of a group of animals we understand nothing more than a diagram, embodying all the organs and parts which are found in any group, in such a relation as to render it possible to forecast alike excessive development. It is, in fact, simply a contrivance for rendering more distinctly comprehensible the most general propositions which can be enunciated with regard to the group, and has the same relation to such propositions as the diagrams of a work on mechanics have to actual machinery, or those of a geometrical work to actual lines and figures. We are particularly desirous to indicate the sense in which such phrases as Archetype and Common Plan are here used; as a very injurious realism—a sort of notion that an Archetype is itself an entity—appears to have made its way into more than one valuable anatomical work. It is for this reason that the term Archetype had not so high authority for us. Other authors have been likely to use it. We prefer the phrase 'Common Plan' as less likely to mislead.

There are two modes in which the Archetype or Common Plan of any group of animals may be set forth. In the first, the community of plan among the members of each group would be the characteristic feature which would be brought out by being compared together, the general Common Plan would be deducible. But this analytical method (which has been carried out to a certain extent for the Mollusca by the writer in a Memoir in the 'Philosophical Transactions' for 1859) would require more space than we can here devote to it; we must, therefore, take the opposite course, and, assuming a Common Plan, trace out its modifications in the subordinate plans, and explain the laws by whose operation these modifications are brought about.

The assumed Common Plan or Archetype of the Mollusca may be represented by fig. 1, 1:—

This figure is supposed to be bilaterally symmetrical, and the following parts and regions are to be distinguished in it:—

(1) The head.

The head is suspended, and which corresponds with what is commonly termed the dorsal region. The word dorsal, however, is vague, being used in different senses in various divisions of the animal kingdom, and is therefore best avoided in the present case. For the same reason, the opposite region (N) is termed, not ventral, but Neural, inasmuch as it is the region in which the great centres of the nervous system are placed. The termination (a) is the anterior or oral end of the animal. Opposite to this (a) the body is divided into two parts (b, c). These two parts are the foot (b) and the head or Prosoma (c). The foot bears the organs of locomotion, and a large part of the body may be thrown into a muscular enlargement on each side, just below the junction of the head with the neural region—the Epipodium (ep). The mass of the body between the foot proper and the abdomen, or part it may called the Prosoma, and whose limits cannot be very well defined, though it would be very convenient to have a name for it, may be termed the Mesosoma (m).—body; and for what is loosely called the head the Prosoma might be better reserved. However the part of the head or Prosoma are two pairs of organs of sense: the Eyes (which may be supported on pedicles—Ommatophores, and the Tentacles. In the head region the integument may be peculiarly modified and may form a pellucide layer, which may be called the anus, and when so modified it is called a Mantle (Pallium). In front of the anus again the Branchiae (t) project, as processes of the head region. Among the internal organs we need only point out the position of the Heart (s, 9), which lies in front of the branchiae in the head region; and the
Nervous Ganglia (α, γ, z), of which there are three principal pairs arranged around the alimentary canal, which they encircle by means of their commissures.

Fig. 1.

I. The Ideal Archetype or Common Plan of the Mollusca.
II. Its modifications in consequence of the development of an abdomen and consequent neural axes of the intestines. 1, Hypostomus; 2, Peripoda; 3, Cephalopoda.
III. Modifications resulting from the development of a post-abdomen and consequent hemal axes. 1, Hypostomus; 2, Pedasterbranchia Gasteropoda. IV. Primarily neural axis modified by subsequent changes. 1, Lambellicrania Mollusca; Neural Mollusca. 2, Brachiopoda. 3, Polyzoa.
V. Hemal Mollusca (Anodiscidae). 1, simple hemal axis, as in Appendicularia; 2, after hemal axis the intestines is bent back, and an atrium is formed; the branchial sac remains comparatively small; 3, the branchial sac comparatively large.

The letter have the same signification as in these and all the other figures, with the exception of figure 10.

Such is the Common Plan of which all Mollusca whatsoever may be regarded as modifications; the next question is, to consider the laws according to which the plans of the great sub-classes of the Mollusca may be derived from it.

2. Modifications of the Common Plan. — The structural peculiarities of all known Mollusca may be very simply accounted for by the successive or defective relative development of certain regions in the archetype, more particularly of one or other parts of the Hemal Region. Of this region the portion which lies in front of the anus may be conveniently termed the Abdomen, while to that which lies behind it the term Post-abdomen may be applied. Now, if it be supposed that the Abdomen grows out of proportion to the rest of the body, constituting a kind of prominence, and that the intestine passes into the outgrowth so as to form a sort of loop (α), it is clear that the open angle of this loop will be turned towards the neural surface; and the intestine may be appropriately said to have a Neural Flexure. On the other hand, if it be supposed that the Post-abdomen grows out in the same way, and draws into itself a loop of the intestine, then the open angle of the loop will be in the opposite direction, and the intestine will be flanged on the surface; the intestine therefore may in this case be said to have a Hemal flexure (iii.). It will be readily understood that either Abdomen or Post-abdomen may develop a mantle or not, and that the existence or absence of this mantle has nothing to do with the question, however much it may affect the external appearance of the resulting form.

Again, the extent to which the Abdomen or Post-abdomen is developed may have a great influence on the relative position of certain organs of the Mollusca. Thus, in the first place, the position of the anus may become greatly altered. When there is a neural flexure it will acquire a direction towards the neural surface and backwards, the final approximation to the median line being dependent on the development of the abdomen on the one hand, and that of the neural region on the other. Again, if the outgrowth of the abdomen take place, not symmetrically, but more or less on one side of the median line, the final position of the anus will be towards the opposite side and to the right or left, as the case may be.

It is even conceivable (this amount of modification indeed actually obtains in nature) that by an exceedingly one-sided development of the abdomen, the anus may be thrown round on to the hemal side. Its final position therefore must not be regarded as certainly indicative of the direction of the flexure by which it obtained this position. Where there is a hemal flexure again, the direction of the anus will be normal; in which case, the anus is the hemal side, and backwards; its approximation to the head, its asymmetrical position, and the amount to which it may be thrust backwards and towards the neural side, depending upon conditions of the same order.

It is not merely the anus which is affected by these changes however; the branchiae (and the heart which follows them) undergo similar transpositions, whose nature and origin it is very necessary to understand, in order to appreciate their value as organic characters. M. Milne-Edwards long ago pointed out the singular fact that, in certain Mollusca, the branchiae are in front of the heart, while in others they are behind it. The latter he termed Opisthobranchia, the former, Prostombranlia. It will be seen that our Archetype is Opisthobranchia. Now, it is easy to understand that if an Abdomen were developed in front of the heart, without involving the cardiac region, the Mollusca would remain opisthobranchia; if however it were more extensively developed, so as to involve the heart and branchiae, the heart from having been in front, would eventually take a position posterior to the branchiae, and the Mollusca would thus become prosobranchia. So, with regard to the development of a Post-abdomen, its effect on the position of the heart and branchiae, and on the development of the neural and hemal surface which it involved. It follows, therefore, that Opisthobranchia may co-exist with either a hemal or a neural flexure, or with none; while Prostombranlia indicates one or the other, but not which; and that these organic characters, however valuable, are secondary to and therefore of less importance than the neural and hemal flexures (that is, development of an abdomen or post-abdomen), on which they depend. Dealing with the facts furnished by adult structure alone then, there are two primary modifications of the Molluscan Archetype, which may be shortly termed the Neural and Hemal Plans. The Cephalopoda, Pulmonata, Peripoda, Lamellibranchia, Brachiopoda, and Polyzoa, are the molluscs which present modifications of the Neural Plan; the Heteropoda, Gasteropoda, Tectibranchia, Iniferoibranchia, Cycloibranchia, Tubulibranchia, Nudibranchia, and Astidinea, are those which present modifications of the Hemal Plan.

3. The Neural Plan and its Principal Modifications. — Milne-Edwards has proposed a division of the Mollusca into the Mollusca proper, and the Molluscoidea (Molluscoidea), including under the latter class those Polyzoa-like molluscs, the Anodiscidae. Believing these Molluscoidea are as truly and wholly Mollusca as any other Mollusca, we nevertheless consider the distinction drawn by the eminent French naturalist to be very important, and that it should be retained as a primary subdivision of the great Hemal and Neural Divisions. In the hemal division the limits of the Molluscoidea are the same as for M,
Milne-Edwards; but in the neural we include somewhat more. In fact, if the most fitting definition for this subdivision be those Moluscs which have the neural region comparatively little developed, and the nervous system reduced to a single or at the most a pair of ganglia, while the mouth is usually surrounded by a more or less modified cirrlet of tentacles, then we shall find that, in the neural division we must include the Brachiopoda with the Polyzoa.

Commencing our study of the morphology of the special groups of the Moluscs with the Neural Division; and with the Moluscoid sub-division of the neural forms, we have to consider first, the Polyzoa and the Brachiopoda:

**Fig. 2.**

The Polyzoa.—Conceive the abdomen of the Archetype to be greatly prolonged, the neural region with its appendages, the organs of sense and the heart remaining undeveloped so that the anus comes into close opposition with the oral extremity, while the edges of the latter are produced into long ciliated tentacles, and the result will be a Polyzon, which needs only the power of gummation to give rise to those composite aggregations which are so characteristic of the group.

The Polyzoic type itself presents five subordinate modifications in the five principal orders of the group:—the Cyclostomata, Clenostomata, Chelostomata, Hippocrepia, and Pedicellata.

In the first three, the body of the Polyzon when fully expanded is completely straightened, there being no permanent fold or inversion of the integument. In the last two there is such a permanent inversion.

In the Cyclostomata the horny or calcareous deposit in the integument of the abdomen joins the soft parts by an even level edge, and there is nothing which serves as a cover or operculum for the retracted Polyzon.

In the Clenostomata (fig. 2, 3) the margins of that portion of the abdomen which is inverted in the retracted state are produced into a toothed horn, shelly, which can be retracted by special muscles, and which serves as an operculum.

In the Chelostomata (fig. 2, 1) the horny or calcareous deposit takes place in such a manner that the hardened integumentary portion of the axial region constitutes a sort of lid, regularly articulated upon the hinder portion, and provided with proper occlusor (or perhaps levator') muscles. It should be noted that the anal aperture is directly away from this lid or operculum.

In each of the previous divisions the tentacles are arranged on a circular disc, or lophophore, of whose edges they are prolongations; but in the great majority of the Hippocrepia (fig. 2, 5), which are all fresh-water forms, the lophophore is so produced into the arms on the anal side as to assume a horse-shoe shape. It is important to consider this in connection with the peculiar features presented by the Brachiopoda.

Thirdly, we venture to regard the peculiar genus Pedicellina (fig. 2, 4) as constituting an order by itself. Essentially a Polyzon, it is nevertheless distinguished from all other Polyzoa by the circumstance that its tentacles are united together by a membrane into a cup, which cup is never protruded far beyond the general boundary of the body.

The Chelostomata are remarkable for possessing two kinds of moveable appendages—Tolellaria, whip-like processes, articulated to a bulb containing muscles by which they are moved, and Ariculata or short processes of the head (fig. 2, o). The structure of the latter is of great interest in a morphological point of view, and demands particular attention. They consist of a larger piece, or valve (p), shaped like a bird's head, and produced into a longer or shorter process of attachment, to which a smaller valve (e), representing the bird's lower jaw, is articulated. Stalked or sessile, these articulata present during life an incessant snapping action, produced by the alternate contraction of two sets of muscles, which arise from the concavity of the 'skull' of the bird's head by wide fan-shaped origins, and seem to be inserted by narrow tendons into the smaller articulated valve. The one tendon (e) is inserted into the smaller valve in front of the line of articulation, and the other (a) behind it, and therefore by their alternate action they raise and depress the lesser valve upon the larger.

**Fig. 3.**

The Brachiopoda.—Now, if we compare the relative positions and mode of articulation of the operculum and cell of a Chelostomatous Polyzon, or of the two valves of an avicularium, with those which obtain in the shells of the typical Brachiopoda, such as the Terebratulidae and Brynhellidae, the resemblance will be found to be very strong; and still more so, if in addition the arrangement of the muscles be taken into consideration. In such a Brachiopod, in fact (fig. 3), the shell is composed of two valves—one large, excavated, and produced into a canal or tube, through which a pedicle of attachment passes; while the other is smaller and more or less flattened. The two valves are articulated together by means of a socket in the smaller valve and a tooth in the larger, on each side, the intermediate space being free, just as the operculum of the Polyzon is united with its cell, or as the lesser valve of an avicularium is articulated with the larger. So likewise the anal extremity of the Brachiopod is turned from the smaller valve. Then the arms of the Brachiopod are essentially comparable to those of the lophophore of a Hippocrepian Polyzon, except that their direction is different; the calcified supports to which they are fixed in many Brachiopoda are so variable in form and so extensively absent in others, that their exu-tence can in nowise affect the homology of the parts. Again, if we leave out of consideration the pedicle muscles (which are however, in all probability, as Mr. Hancock has shown, the homologues of the retractor of the Polyzon), the arrangement of the other muscles is precisely what we have seen to obtain in the avicularium: the adductors which pass from the larger valve to be inserted into the smaller, in front of its point of support, corresponding precisely with the occlusor muscles of the avicularium; while the cardinal muscles, which arise from the larger valve, and pass to be inserted into the cardinal process of the smaller, behind the point of support, are identical with the divaricator muscles of the avicularium.

The existence of distinct muscles for the purpose of separating the valves of the shell is characteristic of the Polyzoa and Brachiopoda, the only approximation to such an arrange-
ment at present known among the Lamellibranchiata being presented by the Pinctada.

Finally, if the great proportional size of the Brachiopoda, their pedunculated attachment, their thick and solid shells, and their simple forms, be brought forward as arguments against the view we take of their essentially polyzoic nature, we would remind the objector of the like opposition in such features between Bolechia and Botryllus, or Apisidum, among the Ascidians.

Two principal modifications of the common Brachiopod plan are to be observed. In the Teredolitidae and Rhynchosomellidae, and in all probability in their extinct allies the Spiriferidae, Orthidae, and Productidae, the muscles are always arranged in three sets—Adductor, Cardinal, and Peduncular. At the same time the mantle (whose homology with the produced edges of the non-retractile part of the abdomen of a Polyzoa is at once appreciable), though divided into two distinct lobes in front, is continuous and entire behind, that is, towards the peduncle. A still more remarkable feature in their organisation is that, at least in Waldheimia and Rhynchosoma, there is no anal aperture, the intestine terminating in a coxum, directed towards the middle of the large valve.

In the Cramiidae, Diciniidae, and Lingulidae the muscles have a very different arrangement, which could only be rendered intelligible by detailed descriptions and illustrations, as the homologies of these muscles with those of the other division are not yet determined. The lobes of the mantle again are completely separated (Dicinia, Lingula, Crania?), and the intestine opens upon one side of the body between these lobes. There are no teeth, and the articulation of one valve with the other and the modes of attachment vary remarkably; Lingula having a long peduncle; Crania being attached by the surface of its lower valve; and Dicinia having an aperture in the corresponding valve through which a portion of the adductor passes, and spreading out at its extremity into a sort of plug, acts as a pedicle.

**Neural Mollusca.**—The Lamellibranchiata. In all Mollusca proper the neural region is developed to a much greater extent than in the Molluscoidea, and there are always three pairs of ganglia, two Cerebral, two Pedal, and two Parieto-Splanchnic (or branchial). The special characters of the Lamellibranchiata, as modifications of the Archetype, are the following:—The mesial region is well developed in its abdominal portion, but forms no prominent sac-like vessels, into which the viscera enter in the adult condition. Its edges are produced into extensive pallial lobes, which are arranged on each side of a longitudinal plane, and not above and below a horizontal plane (or more properly behind a transverse one), as in the Brachiopoda. The mouth is surrounded by a fringe, representing the tentacles in the Molluscocida (as may be well seen in Pecten, fig. 4, 4) which is produced laterally into elongated 'palps,' but is totally unprovided with any mandibular apparatus. The intestine passing from the stomach either forms a simple loop with a second open angle directed hemisally, or this loop may be much coiled and convoluted: the intestine finally passing over the great posterior adductor and terminating between the lobes of the mantle behind it.

The foot may be more or less largely developed, but never presents any clear distinction into prosoco- and metapo-lum, unless indeed, as we are inclined to suspect, the whole free portion of the foot of the Lamellibranchiata ought to be regarded as modified metapodium. Besides the pedal muscles, the Lamellibranchs possess one or two characteristic muscles—the adductors, which approximate the valves of the shell, and whose greater or less development seriously affects the ultimate form of the animal. The gills deviate but little from their archetypal form and position in some Lamellibranchs, such as Trigonia and Pecten, being merely thrown downwards by the development of the mantle. In Nucula (fig. 4, 3), their inner edges are united posteriorly, but they remain comparatively small. In the majority of Lamellibranchs, however, the gills are exceedingly large in proportion to the rest of the body, and consist of two double plates, which are united with the mantle and with one another, in such a manner as to divide the pallial cavity into two chambers, a supra- and infra-branchial, which communicate only by the passage between the anterior edge of the branchial and the foot, and by the multitudinous perforations in the branchial plates themselves.

It is in the absence of external organs of sense or of any buccal masticatory apparatus, and in the peculiar arrange-
The forms, the former being as much as possible elongated longitudinally, the latter attaining the extreme of concentration about a centre. At the same time there is a reduction of parts to a minimum, as shown in the absence of a second adductor, and of any foot in the adult state. The differences between these forms are, however, decidedly less than those which may be observed between the extreme forms among the Cephalopoda or Gastropoda.

The Pteropoda and Pulmonata.—The Lamellibranchs are, as we have said, curiously exceptional in presenting the general features of the Mollusca proper, without that singular buccal apparatus which we meet with in all other members of the subdivision, whether neural or hemal, and whose peculiar nature is described below. Again, they are exceptional in the vast development and symmetrical longitudinal division of their mantle, and in the corresponding division of their pallial shell into two pieces or valves—characters we shall not meet with again in any modification of the Common Plan.

In the Pteropoda and Pulmonata the mantle is never developed into such lateral lobes, and the shell to which it gives rise never consists of two pieces, but is constituted by a single mass, which either has the form of a flat plate or presents some modification of a cone. Again, the foot (or some part of it) is always well developed, presenting no obvious distinction into regions in the Pulmonata; but in the Pteropoda often exhibiting a well-marked meso- and metapodium, and always presenting a characteristically large epipodium—an organ in which these Mollusca constitutes the so-called 'wings,' from which their name is derived.

There is usually a well-developed mantle in the Pteropoda and Pulmonata, and its walls act as a branchial surface without being produced into true gills—(Hyales?; the sea-water in the marine Pteropoda and the air in the terrestrial and aquatic Pulmonata being inspired and expired into its cavity.

In the Pteropoda in general, the aperture of the pallial cavity and that of the anus, are situated upon the posterior surface of the body, in accordance with the neural texture of the intestine. The anal aperture however is usually thrust to one side of this surface, and, in Limacina and Spirula, this lateral thrust has taken place to such an extent, that not only the anal aperture, but that of the mantle cavity, is thrown up completely on to the dorsal surface. This latero-dorsal, or dorso-plantar aperture, is regular in the Pulmonata as it is exceptional in the Pteropoda.

In the Pteropoda and Pulmonata some most important modifications of form are produced by the greater or less development of the mesosoma on the one hand, and of the mantle on the other. The predominance of the latter is to be observed in such forms as Cretia, Creedora, Hyales, and Hetia; while the former may be seen in Pneumoderma and in Limas. In the latter the mantle is very small, and in the former it is almost if not entirely absent; what is ordinarily considered as the mantle in this mollusc being in fact nothing more than the mesosoma. The like condition together of parts so essentially different has taken place, we shall find, in the Nudibranchiata and in the Heteropoda.

The Cephalopoda.—In the Pteropod forms, Pneumoderma and Cletus, a hood, giving off long processes covered with suckers from its inner surface, surrounds the oral aperture, and there is every reason to believe corresponds with the propodium, whose lateral halves have united over the mouth. If the like process were to take place in a Cretia, but to a greater extent, so that the mouth were thrust back between the halves of the mesopodium, and the propodium and mesopodium formed one continuous tentacular orifice around the oral aperture; and if at the same time the two halves of the epipodium united posteriorly into a funnel-shaped tube, the Cretia, so far as its external organization goes, would no longer be a Pteropod, but would have become a Cephalopod. In fact, the Cephalopod may be derived from the Archelopseus by supposing these modifications. The mantle is always well developed, and its cavity incloses one or two pair of gills. The two halves of the epipodium are united behind into what is called the funnel, a peculiar apparatus, of great importance in the economy of many Cephalopods; and in the majority of the group the sides of the foot, having united in front of, and forming a complete sheath for, the head, are produced into eight or ten processes, the so-called arms, on which are set the acetabula, or suckers.

Fig. 5.
shell, and in the nature of the appendages into which the edges of the foot are modified—characters which do not attain to ordinal importance in other divisions of the Mollusca.

Having thus glanced at all the leading modifications of the Neural Plan, we may next turn to the Hemal Plan, commencing with its Molluscoïd modification constituted by the Ascicidaea alone.

The Ascicidaea.—As a Molluscoïd group, the Ascicidae are characterized, in the first place, by the rudimentary condition of their whole neural region, and by the reduction of their nervous system to a single intra-oesophageal ganglion. Besides these, however, their organisation presents certain characters which appear at first sight very remote from such a Common Plan as has been described, and hardly deducible from it. An Ascidian, in fact, is usually fixed by one extremity of its body, and presents at the other two apertures. One of these leads into a wide cavity, whose entrance is fringed with a circle of tentacles, and whose walls (except along the middle line anteriorly and posteriorly) are perforated by innumerable ciliated apertures, and often thrown into folds, by which their surface is greatly increased. At the bottom of this cavity—the branchial sac—a second wide aperture leads into the alimentary canal, which invariably presents a hsemal flexure, and then almost always bends backwards neurally to terminate in a second wide cavity. This, the atrium, whose more external portion is usually termed the cloaca, opens externally by the second or cloacal aperture, and extends along each side of the branchial sac up to its median line of attachment—communicating freely with its cavity by means of the small ciliated apertures which have been mentioned. The single ganglion lies between the oral and cloacal apertures.

Fig. 7.

Ascicidaea.—1. Botulina. 2. Ophiola. 3. Bythula. 4. Intestina of Periphorea. 5. Cloeon. 6. Stylo. 7. Appendicularia. a. oral aperture; b. anal aperture; c. or extremity of the intestine; d. cloacal aperture and atrium; e. branchial sac; f. hypo-pharyngeal band; g. tent. g. gastropod; h. pedal ganglia.

Now, in what manner is this form derivable from the Archetype? It is to be remarked, in the first place, that the pharynx, large in the Polyzoa, becomes comparatively enormous in the Ascicidae; while the tentacles, which were very large in the Polyzoa, are in the Ascicidae comparatively small. Next, with the development of a post-abdomen, the intestine acquires a hsemal flexure; but instead of the anal aperture remaining on the hsemal side, it is bent round, by the same process as in Spirifera and Limacina, but in the inverse direction, so that the cloaca is not at all developed, and that its free margin remaining small and narrow, has followed the anus to the neural side, while its cavity has extended up on each side of the pharynx to the middle of the surface of the latter, carrying to a great extent a process of which the outline may be seen in Cymbula, and giving rise to the atrium;—imagine also that the sac thus constituted externally by the inner surface of the mantle (third tunic), and internally by the pharynx, both separated by minute apertures—and the result would be an Ascidian.

Such is the manner in which the Ascidian type is derivable from the Common Plan. Of this type the group presents three subordinate modifications. The first is that presented by the extreme species of the type (fig. 7, 7), in which a manner represents permanently the larval state of the more perfect members of the group—swimming by means of a long rapidly-vibrating tail, like that of a tadpole. In Appendicularia there is no cloacal aperture or atrium. The mouth opens into a wide pharynx representing the branchial sac of other Ascicidae; from this a gutlet leads into the stomach. The narrower intestine passes from the stomach, forwards and to the hsemal surface, where it turns back horizontally, the mouth being surrounded by any special cavity. Appendicularia therefore might be said to be a form in which the process of modification of the Molluscan Archetype into the Ascidian Type is arrested half way; such a gutlet is the Cynthis, Botula, Perophora, Botryllus, the branchial sac attains so great a proportional size as to occupy the whole, or nearly the whole, length of the body, the intestine lying on one side of it: these might therefore be well denominated Ascicidae Botulinae. Brachiata Ascicidae, the other hand, in Clionea, Apiditea, Polycentrum, Salpa, the alimentary canal lies completely behind the branchial sac, which is proportionally small, and these might therefore be termed Ascicidae Intestinae. Intestinal Ascicidae. A very complete mutual representation will be found to obtain between the members of these two groups.

Hemal Mollusca.—In passing from the Hemal Molluscoidea to the Hemal Mollusca, we find the same new features presenting themselves as in the Neural Division, the transition being even more abrupt, from the absence of any representative of the Lamellibranchiata. In all these Mollusca, in fact, there is a more or less well developed foot; a distinct head, with the organs of sense and buccal armature; and three pairs of ganglia—cerebral, pedal, and parieto-mesophract.

The modification of the Common Plan is carried to a less extent in this than in the Neural Division, the chief varieties of its forms depending on the changes in the shape of the shell with which the majority are provided; on the greater or less development of the different regions of the foot; but most of all in the relative proportions of the mesosoma and mantle.

If we divide the Hemal Mollusca into two great groups—the one consisting of the Heterogena, Scutibranchiata, Tubulibranchiata, Pectinibranchiata, and Cyclostomata, families, which are most intimately allied, and which are connected and derived by the diverse arrangement of the reproductive organs; and the other of the Nudibranchiata, Inverceibranchiata, and Teuthibranchiata, families in like manner united, among other characters, by their common hermaphroditism, then we shall form in each group two extremes of form—the one resulting from the great development of the pallial region, the other from that of the mesosoma. In the Diccous Division, Denudalium, Veneridae, and the ordinary Pectinibranchiata may be regarded as examples of the former case; in the other case, in the Mollusca the Division the Inverceibranchiata and Tectibranchiata; while the mantle becomes rudimentary or absent altogether in the Diccous Foliolidae, in the Monocous Physalidz, and the Nudibranchiata in general, where the region from which the so-called branchial processes are derived, and which is commonly called the mantle, is not the homologue of the mantle of Atlanta for example, but of its mesosoma, which
here, as in *Firoloides*, constitutes the main portion of the
body.

**Fig. 8.**

Heteropoda.—8, *Atlantic*; 9, *Firoloides*.

*Fig. 9.***

The foot in the Monoceros Hemal *Mollusca* rarely presents any special development of its different regions, except that in certain forms—namely, *Alpavica* and *Gasteropteron*—the epipodium is as well marked as in the *Pteropoda*, and serves the same end in locomotion. This is well known in *Gasteropteron*, and we have seen a tropical *Alpavica* fly through the water in precisely the same way as a *Pteropod* would do. These epipodial lobes have been frequently called mantle, although the true mantle is a most distinct and obvious structure.

In the Diceros group the epipodium is never well developed, presenting itself at most under the form of little lobes and processes; at least it would seem probable that the neck-laplets and head-laplets of the *Trocchae* are rudiments of the epipodium. On the other hand, it is in this group that the propodium, mesopodium, and metapodium attain their most complete and distinct form; as in *Atlantic*, where the propodium constitutes the anterior flattened fin, the mesopodium the rounded sucking disc, and the metapodium extends backwards, as the tail-like lobe which carries the operculum. In *Firoloides* we find that the mesopodium has vanished, and the metapodium has taken the form of a mere filament, while the propodium constitutes the stout swimming fin.

In the ordinary *Pectinibranchiate*, on the other hand, the foot may not be differentiated into its subdivisions at all, the metapodium being marked only by the position of the operculum, when this exists, as in *Buccinum*. In other cases, as in *Oliva* and *Sigaretus*, a deep cleft marks off a very distinct propodium from the conjointed mesopodium and metapodium; in others, as in *Pierceres*, the metapodium is so specialised as in *Atlantic*; while again, in still others, as in *Navicula*, the three constituent parts are distinguishable—the propodium constituting the hood in front of the head; the mesopodium the creeping disc; and the metapodium the opercular lobe. (Fig. 9—2 and 3.)

Having thus passed in review those models of arrangement of the various organs of the *Mollusca* which constitute the Common Plan of the group and the subordinate plans of its leading subdivisions, we have next to consider the peculiarities presented by these organs themselves, or, in other words, those more striking features in which the organs of the *Mollusca* differ from those of the *Vertebrata*, *Anamnia*, and *Radiata*. The most important organs, in this point of view, are those of—1, the Alimentary; 2, the Circulatory; 3, the Respiratory; 4, the Renal; and 5, the Nervous System.*

1. The Alimentary Organs, in certain *Mollusca*, present two kinds of apparatus which are met with in no other division of the Animal Kingdom. The first of these is that peculiar manducatory instrument usually called the 'tongue', which is possessed by all the *Mollusca* proper, except the *Lamellibranchiata*; and for the first description of those true structure and mode of action we are, we believe, indebted to Mr. Thompson (see article 'Tongue,' in the *Cyclopedia of Anatomy and Physiology*), although the organ itself had been worse or less an object of attention ever since the time of Cuvier.

**Fig. 10.**

Tongue of *Radiola*.

1. a, the cartilaginous plates which constitute the pulley over which the elastic plate 2, supporting the series of teeth 3, plays; 4, a view of the anterior and posterior portions of the muscular muscles of the tongue. 1 is an internal view, and 3 is a view from above, of the entire apparatus.

The tongue is essentially composed of a cartilaginous mass, with a pulley-shaped upper and anterior surface, which projects from the bottom of the oral cavity. An elastic plate plays over the pulley, and is attached at each end to muscles which arise from the upper and lower surfaces of the cartilaginous mass. Along the middle line of this elastic plate successive transverse series of strong recurved teeth are set—new ones being continually formed behind as the old are worn away—in a sort of persistent dental sac.

When the tongue is brought into play it is protruded by appropriate muscles from the cavity of the mouth, and its extremity is firmly applied against the body to be rasped. The superior and inferior sets of muscles, which are inserted into the corresponding ends of the elastic plate, now contract alternately, and the resulting action is precisely that of a circular saw. It is by means of this apparatus that the Carnivorous *Radiola* bores through the shells of the animals upon which they prey, and perforates shells, which have been thus emptied, abound on every coast.

The other appendage of the alimentary canal peculiar, as far as we at present know, to the *Mollusca*, is what is termed the *Crystalline Style*, a transparent, usually elongated body, which projects by one end into the stomach, and is lodged for the rest of its extent in a sac formed by a diverticulum of

* Our limits preclude the consideration of the tegumentary and genital systems, whose peculiarities, however, are less exclusively *Molluscan*. 
that organ. The Crystalline Style is found in a great number of Lamellibranchs (to which it has erroneously been supposed to be confined), but has hitherto been observed in only a few Pectinibranch Mollusca, such as Pterocera, Striasoma, Tropaea, and Murex. Its function is wholly unknown. As the alimentary appendages, the Liver in one group, the Ascidians, depart sufficiently from the ordinary plan to deserve particular notice. In these animals (fig. 7, No. 4, &c) it always consists of a series of narrower or wider anastomosing tubules, commencing in ceca upon the outer surface of the intestines, unites in a main trunk, and terminates by a narrow duct, in the stomach. In the Botryllida the hepatic tubules are remarkably wide.

2. The nature of the Circulatory System in the Mollusca is so peculiar and exportunate extensively as regards the important point whether they possess a true closed system of vessels or not. Without entering into any discussion of the various arguments used on both sides of a dispute which is in some respects verbal, we may be permitted shortly to state our own conclusions on the subject. In the Polyzoa there are no special circulating organs, if we except the cilia with which the pericircular cavity is often lined, and which keep up a continual current in the pericircular fluid; nor do we imagine that any one will insist that the pericircular cavity is not a sinus, but has a truly venous lining membrane.

In the Ascidians there is a heart, but it is a simple muscular sac, open at each end, and possessing the extraordinary property of drawing blood from the body by means of cilia, thus circulating its blood first in one way and then in the opposite. The blood thus poured out is driven by any open channel in which assuredly no separate lining membrane is demonstrable. Indeed it is difficult to comprehend how any animal with a living tube and his microscopic reaction that here, at any rate, the circulation takes place through lacunae, and not through vessels with distinct walls.

In the Brachiopoda a very remarkable vascular system has been discovered, and this one of two hearts (in Rhynchonella of four), each composed of an auricle and a ventricle; the former being in free communication with the pericircular venous sinuses (pericircular cavity, notis), while the latter ends in a sorta, whose branches undergo a regular distribution. Such is the circulatory system in the Brachiopoda according to Professor Owen; but our own inquiries have tended to strengthen very greatly the doubts first raised by Mr. Hancock as to the true nature of this so-called cir- cumulatory system. It fact these inquiries lead us to doubt whether any of these so-called ‘hearts’ of the Brachiopoda have anything at all to do with the circulating system; inasmuch as, in the first place, we are pretty confident that no ‘arteries’ are given off from the spines of the ‘ventricles,’ as has been said, and think that most of the processes arise independently. Secondly, there is no evidence at present, either indirectly from structure or directly from observation during life, that the so-called ‘hearts’ of any Brachiopod are contractile. Thirdly, the multiplication of these hearts to four in Rhynchonella seems not a little to militate against their cardiac nature.

We may fairly conclude then that, for the present, the nature of the circulatory system in the Brachiopoda must be regarded as an open question.

Mollusca Proper. The doctrine first advanced by M. Milne-Edwards that in these Mollusces the circulating system is always more or less incomplete, has met with a wide acceptance, but also with no small opposition. So far as the molluscan system becomes developed in the higher forms, microscopic observation during life, are concerned, we do not understand how the truth of M. Milne-Edwards’s doctrine can be questioned. If the term ‘venous lining’ is to have any meaning but a non-natural one, assuredly it cannot be said with truth that the kind exists in the sinuses of Fritolida, or of Atlantic, or in those of the Pteropoda.

In the larger Mollusca, on the other hand, much depends on the verbal question—‘is the so-called ‘vein’ or ‘sinus’, or “the liver’—as it were there where there is a less or more complete vein system, there must be a greater histological differentiation corresponding to that which exists in the Vertebrata be re-quired to constitute a vein, evidence of the existence of any-thing of the kind in the greater proportion of the venous blood-channels of these forms are at present wanting.

As regards the grosser structure of the circulatory system in the Mollusca proper, it may be observed that, in the Lamellibranchs there is either a single auricle and a single ventricle (Ostrea), a single ventricle and a double auricle (most Lamellibranchs), or two auricles and one ventricle (Arca). In all other Mollusca, except the Cephalopoda, there is a single auricle and a single ventricle. In the Cephalopoda the heart is essentially similar to that of the Lamellibranchs, insomuch as it consists (in the Diobranchiata) of a single auricle and a single ventricle, being represented only by the regular contraction of the so-called ‘branchial hearts,’ which are dilatations of the afferent branchial veins, but by that of the gills themselves.

The nature of the so-called Pericardium in the Mollusca has been much misunderstood. It is most important to re-collect that in no case is there evidence of its being a closed serous sac, comparable to the pericardium of the higher animals. On the contrary, wherever it has been examined with sufficient care (Lamellibranchiata, Cephalopoda, Perip- poda, Nudibranchiata, and Cephalopoda), it has been found to be a blood-sinus, which in some cases (Pteropoda, Cephalopoda (1), Lamellibranchiata (1), and Heteropoda) communicates with the exterior by the mediation of the renal organs.

3. The Respiratory Function is performed by modifications of several distinct parts in the Mollusca. 1. By the general surface of the pallial cavity, which may be more or less adaptively modified; this kind of respiratory organ is to be found in the Brachiopoda, Peripatoda, and Cephalopoda.

2. By specially modified parts of the walls of the palpial cavity into true gills; the whole tendency of the modification of form which these gills undergo is to increase their surface, their thickness, their reticulation, is effected in one of three ways:—a. By the development of simple processes, as in Patella or Atlantic. b. The simple processes become rami-fied, so that the gill eventually consists of a stem with lateral branches, and these again may be subdivided into smaller and smaller branches—Pteropoda, Peripatoda, and Cephalopoda. c. In the Lamellibranchiata each gill essentially consists of a stem with lateral undivided branches, and in such forms as Trigonia and Nucula (fig. 4, No. 3, &c); the branches have precisely this structure. In Nucula the lateral branches are but minute tubules, and in Trigonia they are much longer. In Pecten they turn up at their free ends upon themselves and form a close loop, so that the free end takes a position near the fixed extremity; at the same time lateral branches are produced in the posterior quarter of the gill, and they connect them together by a very loose and open vascular network. Each gill has thus become a flattened pouch, completely open, both laterally and superiorly; the sides of the pouches are very open, and are constituted superficially by the parallel produced and reflected portions of the lateral branches, and more deeply by the very loose network formed by the anastomosing lateral processes. Now, if we suppose that the reflected portion of the outer gill-pouch adheres to the mantle, while the reflected portion of the inner gill-pouch remains free on each side of the foot, but adheres to its fellow behind the foot, thus forming a complete partition across the pallial cavity, the deep vascular network becoming very close, and giving off vertical septa, by which the pouches are subdivided into processes, so that the whole then the result will be such a gill as we meet with in the Oyster, the Unio, and the great majority of Lamelli-branchiata. The minute structure of these branchiæ strikingly resembles that of the branchiæ of the gastropod molluscs, and as has been long since pointed out by Siebold and others, and has given rise to the prevalent idea that the two organs are homologous. Structural resemblance, however, is in itself no true basis for the establishment of homologies, and we are of opinion that the means of breathing are much less likely to be simply analogical. 3. The ‘branchiæ’ of the Nudibranchiata again doubtless subsist to breathe, yet they are developed from the mesosoma, and contain the gastro-hepatic processes of the alimentary canal, and thus do not correspond to true gills. 4. The branchial sac of the Ascidians is, as we have shown, a modification of their pharyngeal sac, resembling
the gills of fishes (especially Amphilius) more than any other structure to be found in other Invertebrata (the nearest approximation perhaps is in the cloacal branchiae of Neopterous Larvae and of some Annelids). Like the wall of the gill chamber of the branchial sac of the Ascidians, in the Ascidian is fundamentally composed of two elements—a superficial strong framework of branchial bars corresponding with the 'gill-branches,' and a deeper vascular network connecting these. The more obvious peculiarities in the structure of the branchial sac of the molluscan kidney produced by the plaiting of its wall into the so-called branchial folds, which may vary in number from four (Cyathus) to a number so great that the wall of the sac appears cramped (Gastropoda).

4. The Renal Organs.—The existence of a special organ for the urinary reception has now been demonstrated in all the great divisions of the Mollusca except the Polyzoa and Brachiopoda. The essential feature of the molluscan kidney is the deposition of a quantity of urinary excretion beneath a free surface, which in all aquatic Mollusca is, by some means or other, freely bathed with water. In Phallusia, for instance, minute rounded sacs, each clothed with a delicate epithelium, and containing one or many concretions, are scattered over the intestine immediately beneath the lining of the atrial cavity. It is probable that the constant current setting through this cavity carries away some portion of the secretion; but the greater part seems to remain, and eventually forms the whole partial surface of the atrium. Here the secreting part of the apparatus appears to be out of proportion to the excretory. In the Peripatoda and Heteropoda the reverse relation would appear to obtain. In these animals, in fact, the concretions have not yet been detected; but the excretory apparatus is an elongated sac, which opens at one end by the side of the anus, and at the other communicates with the pericardial blood-sinus. The sac contracts rhythmically and with great rapidity, so that the blood in contact with its delicate walls must be very efficiently washed. How far the internal communication with the blood-sinusises is available for the same end, is not at present understood. In the Lamellibranchiata (at least in Unio) the pericardial sinus is connected anteriorly with the internal cavities of two spongy bodies—the glands of Bojanus—in which a great quantity of concretory material may be detected; on the other hand, the outer surfaces of these glands lie in a cavity which admits the water freely by an opening placed anteriorly close to the genital aperture. This cavity clearly corresponds with the contractile sac of the Peripatoda and Heteropoda, but no evidence of contractility has yet been observed in it, or in the renal organ itself. Keber also denies that any direct communication exists between the walls of the kidney and the pericardial sinus and the outer sac, but it is somewhat difficult to make sure of this. However this may be, the arrangement of the kidney in Unio is very interesting, from its close analogy with what obtains in the Cephalopoda, where the 'serous cavities' of the kidney are attached to the base of the gills and connect the peculiar spongy venous appendages attached to one of their walls, correspond exactly with the excretory sacs of the Lamellibranchiata, while the spongy appendages themselves are but the glands of Bojanus in another form. Our limits will not permit of the description of the structure of the renal organ in Nudibranchiata and Pectinibranchiata, but it might readily be shown to resemble in all essential points that of the Lamellibranchiata and Cephalopoda.

5. The Nervous System. In the Mollusca the Nervous System consists of the Polyzoa and the Mollusca and the Mollusca respectively present a remarkable agreement in the general arrangement of their nervous apparatus, which consists in the Polyzoa and Archiokiida of a single ganglion placed in the midst of the neural region of the body; in the former case between the oral and anal apertures, in the latter between the oral and cloacal apertures. In the Brachiopoda the nature of the nervous system is only known with certainty in the Terebratulida, where it consists of a single elongated lophophore, running from the tip of the lophophore close to the ganglion, probably representing the 'nervus' of the Ascidians, an organ whose function is not known, but which probably performs, in conjunction with the ciliated sac, the part of an organ of sense. The 'ciliated sac' is, as its name implies, essentially a small ciliated pouch placed between the oral end of the hypopharyngeal band and the

---

memory; but the amount of the value of such conceptions, and of their beneficial influence on the forward progress of science, depends entirely on the extent to which they embrace the whole anatomical peculiarities of a group of animals. Now animals, like all living beings, not only are, but become; and their anatomy, in the widest sense of the term, is to be obtained, not merely by the study of their structure (which is their final anatomy), but also by that of their development, which is the anatomy of the successive states through which they pass in attaining their final condition. Now the Archetype or Common Plan professing to be the embodiment of the most general propositions which can be enunciated with regard to the anatomy of the group, its validity will depend upon its embracing both structural and developmental facts. If it neglect either of these, it will be theoretically imperfect, and will run the risk, at any rate, of being practically erroneous. Before the publication of Von Baer's 'Archetype of the Vertebrata,' unfortunately too little data was known as to the extent notions of archetypes, unity of organization, &c., were open to precisely this objection, their authors having contented themselves with devising hypotheses to fit the facts of adult structure, without concerning themselves whether their hypotheses would or would not also fit the facts of development. Hence the infinite variety of baseless speculations of the 'Nature-philosophie' school; in botany, the unlimited and quite gratuitous demands upon 'abortion and fusion' of parts which Stieda has so justly ridiculed; in zoology such notions as that a Cephalopod is a vertebrate animal doubled upon itself, that an Insect is a vertebrate animal with free ribs, &c.

It is precisely on this footing however that at present our Common Plan or Archetype of the Mollusca stands. We have before us the evidence which might perhaps have satisfied Geoffroy and Oken. Given our plan and certain laws of modification, and all known molluscan forms may be derived from it; but it remains to be seen how far the evidence which would alone have satisfied Von Baer, the evidence of development, justifies the view which has been taken; how far, in fact, our hypothesis is capable of being elevated to the dignity of a theory.

To this end it is by no means requisite to show that every Mollusc has at one time the archetypal form, and is subsequently modified into its persistent condition; to maintain such a proposition it would be necessary greatly to simplify (though not essentially to alter) the archetype, and thus to do away with a great part of its utility in exhibiting the tendencies of every Mollusc. All that appears to be really necessary is to show:—first, that no molluscan form presents features in its development which cannot be reconciled with the archetype; secondly, that the kind of modifications which have been supposed to take place in the conversion of the archetype into the special types are as actually occur.

The first stage of development of the Mollusca resembles that of other animals. The yolk, at first a homogeneous mass, undergoes the process of division to a greater or less extent, its outermost layers eventually becoming converted into a blastodermic layer, the plastic material out of which the future animal is modelled.

In the Mollusca the rounded or oval embryo thus formed either becomes covered with cilia and swims away as a free form (Polyzoa Brachioidea), or it gives rise from one portion of its surface to a long fin-like muscular process (fig. 13, 1.), by whose rapid vibration it is propelled (Ascidioidea, in great part). With what organ of the Mollusca is this 'tail' or 'fin' of the Ascidian larva homologous? This is a very difficult point to ascertain, as the tail arises before the regions of the animal are differentiated. At first sight one might be tempted to consider it as a modification of the velum of the embryos of the Mollusca proper; but its relation to the middle of the neural surface, and its insertion close behind the ganglion, which may be readily observed in later stages, appear rather to indicate that it is the homologue of the foot proper, and probably of the metabolism, as this is the portion of the foot in which the Mollusca appears first.

In the further development of the Ascidioidea there can be no question as regards the Polyzoa, the neural region soon almost ceases to grow, the further increase of the body taking place by the disproportionate development of the haemal region, which constitutes almost the whole of the body of the adult animal, and presents the surface by which it becomes fixed. Again, simple inspection is sufficient to show that the intestine extends into the great abdomen thus developed; that it acquires herewith a neural fixture; that the tentacles are produced from the margins of its oral aperture; and that the pharynx acquires a large proportionate size.

In the Ascidioida the neural region remains in a like rudimentary condition, the haemal region undergoing a similar disproportionate growth; but it is next to impossible to ascertain from the study of development whether this haemal outgrowth is formed behind the anus or before it, inasmuch as the intestine has acquired its complete haemal fixation when its parts are first distinguishable.

In the youngest state in which the different organs are distinguishable, the intestine is almost entirely bent up on the haemal side of the body; the pharynx is a wide cavity (not wider proportionately however than that of a Polyzoa); the tentacles spring from its margin in exactly the same relative position as in a Polyzoa, and there is no atrial cavity. By degrees the pharyngeal cavity enlarges still more, the tentacles remaining comparatively rudimentary (fig. 12, 2). Contemporaneously with these changes, the end of the intestine becomes more and more bent down towards the neural surface, and a cavity, which in another Mollusca would be the mantle-cavity, appears around its extremity; a single or two lateral apertures (subsequently uniting into one) are soon formed, and allow this cloacal portion of the atrial cavity to communicate with the exterior. At the same time the atrium extends on each side of the enlarged pharynx, detaching it from the side of the body, and enveloping it just as a serous sac invests the surface of a viscera. Ciliated apertures (at first one or two only on each side) now pierce
the wall of the enlarged pharynx, and increases in number until it assumes the structure of the perfect branchial sac. Finally, it depends upon the proportional development of the branchial sac, and of the post-abdomen, whether the adult Ascidian shall belong to the Branchial or to the Intestinal subtype.

We unfortunately know hardly anything of the development of the Branchiopoda; but so far as the Polyzoa and Ascidioidea are concerned, it is obvious that the hypothetical modifications of the Archetype do in fact faithfully represent the actual course of development. (See however the remarks, further on, as to the nature of the post-abdominal outgrowth in hemal Mollusca and Mollusca.)

**Development of the Neural Mollusca.** — The Lamelibranchiates. — The first step towards the production of the organs from which the adult Mollusca are derived, is the formation in a longitudinal section of one portion of its surface into a disc with mixed edges, provided with very long cilia (fig. 12, t. 1). Next in the inner surface of the germ the intestine appears as a solid mass, bent upon itself, towards what the eventual development of the foot proves to be the neural surface; its oral portion being placed immediately behind the ciliated disc (9). Finally, the hemal surface behind the ciliated disc gradually gives rise to two lobes of the mantle, upon each of which a third lobe of the foot is formed and a foot更大号, eventually appears. As development goes on (3), the neural surface between the primarily approximated oral and anal apertures becomes converted into the large foot and mesosa of the Lamellibranchiates, which serve to lodge the principal parts of the body, the gills being developed into a great process in Gasteropods. The great posterior adductor makes its appearance on the neural side of the intestine, and by its development the latter is thrown up so as almost to appear to have a hemal flexure. The gills next appear as processes of the body within the cavity, and therefore have not the remotest homology with the pharyngeal branchial sac of Ascidians, any more than the second apical apertures which are essentially dependent upon the gills, the lobes of the mantle with the gills, and with one another have anything to do with the oral and cloacal apertures of the Ascidians.

Finally, it is said that the ciliated disc becomes metamorphosed into the labial paup. This is a point well worthy of further investigation; for the arrangement and form of the appendages in Pecten leads us strongly to believe, as we have said, that they are the homologues of the tentacles in the Ascidioidea and Polyzoa. On the other hand, there can be no doubt that the ciliated disc of Lamellibranchiates is homologous with the ciliated lobes of the Gasteropod embryos; and these, there is every reason to believe, are nothing but the specially modified anterior portion of the epipodium. The tentacles of the Polyzoa would thus come to be the homologues of the ciliated disc of the Lamellibranchiates, but the chain of reasoning obviously depends upon whether the ciliated disc does or does not become metamorphosed into the paup— a position which the more requires confirmation as in the Polyzoa the cilia are now entirely known to disappear. However this may be, what has been stated with regard to the main steps in the development of the Lamellibranchiates fully confirms the hypothetical derivation of the type from the Common Plan.

Pteropoda and Pulmoidea. — In the primary stages of their development no important distinction is to be drawn between the members of this division and those of the last, except that in the Pteropoda the ciliated disc is replaced by two ciliated lobes on each side, and in the Pulmoidea embryos by a contractile organ (the velum hypothalamicum). The primary neural flexure of the intestine in the Pulmoidea, and the development of their mantle in front of the anus (that is, the development of an abdomen), are fully demonstrated by late observations upon their embryology. It is important to remark, that in the Pteropoda the ciliated lobes of the embryo do not become the lateral alae of the adult form, but are a production of the anterior part of the epipodium, which usually disappears in the adult.

Cephalopoda. — In both of these sub-systems a much higher development before leaving the egg, and the modifications which its primary form undergoes are extremely intricate. The first organs of the Cephalopod which appear in the developing embryo cast the mantle, which is simply a thickening in the middle of the hemal surface with somewhat raised edges; around this is a surface representing the mesosa and foot, at one end of which is the mouth, and at the other or anal extremity are placed two little processes, the rudiments of the gills. Again, on each side of the mantle the mesosa is produced into a longitudinal ridge occupying the precise position of the epipodium. As development goes on, the hemal surface occupied by the mantle grows out, and becomes a prominent sac, whose free edges grow outwards in the shape of lobes for some distance anteriorly, but for almost the whole length of the sac posteriorly, give rise to the mantle cavity (v. 2). The intestine passing into the abdomen thus formed becomes completely enclosed in the cavity of the mantle, and the complete organ, open towards the neural side. With all this the epipodium, remaining rudimentary in its anterior region, becomes a free process on each side posteriorly (representing for a time the alae of a Pteropod), but after a while these processes become detached from the body, and the whole of the changes undergone by the margins of the foot are not less remarkable; they are produced from behind forwards into four or five digitations on each side, the anterior pair of which stretch in front of the mouth and unite over it; the digitations elongate more and more, and the mouth is in consequence at last placed in the centre of a sort of inverted cone, formed by the foot and its prolongations—the acetabulariform arms (v. 3).

Such in a very short abstract of Professor Kolliker's most valuable Entwicklungs-Geschichte der Cephalopoden, and it is needless to point out that it is our hypothetical process of modification of the Archetype into the Cephalopod type, in other words.

The necessity for considering the development of the separate families of these Molluscs, as the process, as far as we know, is the same in all. We will take that of a Nudibranch (Antitupa cristata) as a type, having recently had occasion to go over it with especial reference to the palate here under consideration.

The end of the process of yolk-division (which, we may remark in passing, results, not in the formation of 'nucleated cells,' but simply in that of smaller and smaller packets of yolk-droplets) is the umbilicus, a thin, acellular, dermic layer investing the remainder of the yolk. The whole embryo next becomes more or less bell-shaped, a sort of rim, with very long cilia, appearing at the broader end, while a minute prominence is seen at the opposite extremity (t. 1). A straight line drawn from this prominence to the centre of the surface, surrounded by the rim, would have the body of the creature symmetrically disposed around it. On the one surface is a deep pit, formed by the edges of the lateral ends of the acellular layer; on the opposite a delicate transparent cup, the future shell. The line of the future side of the position of the hemal surface and mantle appears (t. 2) by degrees the hemal surface becomes more and more prominent, and the shell larger. With this prominence the embryo is transposed to the right side, so that its position becomes quite asymmetrical (t. 3, 5). At the same time the ciliated rim from being circular is produced laterally into a lobe on each side—the ciliated lobes; the metapodium makes its appearance behind these as a small prominence; and a delicate operculum is formed by the metapodium. The aperture of the mouth may now be observed behind the ciliated lobes and between them and the metapodium; and the internal substance of the germ is seen and the outlines of an alimentary canal, consisting of a rounded gastro-hepatic mass and a narrower intestine, which turns abruptly forwards and upwards, to end on the right side more or less hemiyclic in the before-mentioned prominence, whose position has become thus extensively absorbed, diverticulated by a variety of folds, and by pushing-in of the integument around the anal prominence. Two things are obvious in this series of developmental changes. In the first place, the primary asymmetry of the embryo; secondly, the gradual asymmetry brought about in the development of the portion of the body which bears the shell, and which is a portion of the hemal surface.

Now this is perfectly in accordance with our hypothetical derivation of the Hemal Mollusca from the Archetype, and to this extent only one point remains to be considered—developed hemal surface is to be considered as a post-abdomen, that is, as a post-anaI portion of the hemal surface.

This view has been taken in deriving these forms from the Archetype, because it is much the more readily comprehensible, and has many structural facts in its favour; but we are by no means prepared to assert that the post-anaI
perverted, or arrested, or increased in its course during the growth of the embryo or germ.

Monstrosities in the animal kingdom are treated of under the head Monstrosities. We shall not treat of monstrosities in plants. The study of such growths is not a mere matter of curiosity, as their structure tends to throw light on the true laws of development amongst plants. Monstrosities are more easily made on plants than on animals for the reason of ascertaining the facts of their history during growth, it is nevertheless interesting to obtain a confirmation of these facts from the forms which monsters assume, these forms in the majority of cases being present in the earlier stages of growth through which plants pass. In these forms nature presents us with as it were experiments to test the truth of the general laws of morphology.

This subject can perhaps be best illustrated by reference to special instances. To begin with the Leaves. [Leaves.] In the history of the normal development of the leaves, it is found that they are always arranged in an alternate manner, one leaf above the other, but subsequently in many plants, and even whole families, the leaves become opposite or whorled. In the case however of individuals it does not infrequently happen that the leaves of opposite or whorled-leaved families of plants become alternate. Thus an instance is recorded of Hippuris vulgaris (Mare's-Tail), which in its normal condition is always opposite, it has now and then, its leaves arranged alternately in a spiral upon the stem. (Lankester in 'The Report of British Association,' 18th meeting, p. 55.)

In the formation of the leaf-bud into the flower, one of the earliest changes that takes place is the conversion of the leaves into the organs called Bracts. [Bracts.] Instances are very often seen of monstrous forms of plants in which the leaves are not converted into bracts but retain their leaf-like character. This frequently occurs in the genus Plantago, giving the inflorescence a singularly different character to that which occurs under normal circumstances.

The leaf-bud is always seated in the axil of the leaf, but in the case of the bracts forming the involucre of the Composite, neither the leaf nor its axil is represented in the axils; but in the case of the monstrosity of the common daisy (Bellis), known by the name of Hen and Chickens, flower-buds are developed in the axils of the bracts.

Next after the bracts the Sepals are formed in the flower-bud. [Calyx.] It not unfrequently happens that during the growth of cultivated plants, the sepals are found assuming the appearance of leaves. This is especially the case with the cultivated roses. This tendency to recur to the condition of the leaf is seen in the Gorse, Adonis, and Common mustard. Thus, in the case of Calycophyllum stanleyanum, one of the sepals after the corolla drops off begins to grow into a beautifully rose-coloured leaf. Other instances in this kind are seen in the Buttercup. In plants with inferior fruits (Favor) the germen seems to continue in the axils below the lower part of the sepals which thus produces the peculiar character of these fruits, such as the gooseberry, the currant, the apple, and the pear. In these fruits it is not uncommon to find amongst them leaves growing from the surface of the fruit, indicating the tendency of this sepalary part of the fruit to assume the condition of the leaf. The most remarkable example of this tendency of the sepal to assume the condition of the leaf has been observed in the Goat's-Beard (Tragopogon pratensis), in which the pappus surrounding the minute flower which represents the calyx has been found to have assumed the character of the leaf.

It frequently happens where one of the parts of a flower has a tendency to relapse to the foliar condition, that the whole of them partake of this character. Thus Mr. Austen has recorded very accurately the changes observed in a monstrous form of the White Clover (Trifolium repens). The following changes were observed in his specimens:—

1. Calyx teeth often rise into single leaves, but when compound leaves are formed the division seems to be as follows: the two large equal teeth, which are opposite the vexillum, form one serrate leaf, and another leaf is formed from the axils, remaining entire.

2. Corolla.—The part which here most frequently reverts to a leaf is the vexillum, and this is a perfect one. Of these leaflets, the one are often seen forming simple leaves, as the carina; but their perfect union into a ternate leaf is less common.

3. Stamens.—Whatever changes the flower may exhibit,
these organs are always in a state to be recognised, and their reversion to leaves less frequent than in any other part; so that there is more difficulty in determining the number of leaves which go to form this portion. As two tertiary leaves form the calyx and corolla, it might be supposed that these leaves were constructed out of the same number. The figures represent cases of a stamen reverting to a leaf with a true stamen attached to its stalk on either side; the single stamens of the flower reversed, in some cases form more than a simple leaf; and it is therefore probable that the ten stamens (9 + 1) may be formed out of four sets of tertiary leaves.

4. Pod.—From the well-known character of the pod and pistil of Mentha, it might be expected that instances of the reversion to leaf would be most frequent in this part of the flower; and a series might easily have been produced which would have represented it in every stage of passage; some of these were given. From these it would appear that the pod is not formed of a whole compound leaf, as either two scales, or two abortive leaves, are constantly to be seen at the base of the imperfect pod on either side; the pod is therefore usually formed out of the middle leaflet. In one flower-head however each division of the pistil-leaf had become a pod, with a distinct stem and the ovules inwards.

"Ovules seem to be produced only where juncture of the edges of the pistil-leaf takes place; in other cases leaflets are produced in the place of ovules."

On the other parts of the floral series has been regularly developed, the Pistil occasionally will take the form of a perfect tertiary leaf, and then the axis of the plant is continued through the flower." (Austen, 'British Association meeting'.)

Mr. Austen has likewise recorded in the same place an instance in which the staminal flowers of the Common Maize (Zea Mays) were converted into pistils. In this case we have an instance of the tendency of an organ not to relapse to a lower type, but to assume a higher type of development.

It is very frequently the case that stamens relapse to the condition of petals. This is the case with most of the double flowers, and in the gun; in dragonfly, the bachelor's-buttons, and others, the anthers may often be found tipping the petaloid bodies in the centre of the flower. This is seen as a normal condition in the water-lily.

The recurrence of the pistil to the form of the stamen and corolla is not so frequent, as its assuming the form of the leaf. In the double cherry of our gardens this condition of the pistil is frequently presented. It is this same tendency which is seen in innumerable oranges, in which this fruit is split up into the same number of parts as it possesses carpelar leaves. [FLOWER.]

The most central organ of the plant is the Seed, and its development is the great object of the production of the flowering plant. The young pod is green ever but a changed bud, and during the process of its development it sometimes recovers to the condition of the leafbud, and produces instead of an embryo a branch. These instances will be sufficient to show how instructive the study of vegetable monstrousities really is. Many such have been recorded, and one of the best resumés of the whole subject will be found in Moquin Tandon's 'Terentologie Vegetale'. [METAMORPHOSIS OF ORGANS.]

MONTAGU, A genus from Lamellibranchiatea Mollusca, belonging to the family Kelliidae. The shell is small, thin, equivale, inequilateral, transversely oblong or obliquely oval, surface smooth or concentrically striated, or more or less finely grooved; beaks inflected; inner margina smooth; hinge-margins with a triangular incision and cartilage pit, and a pair of diverging laminar teeth in one or both valves; ligament internal; muscular scars suborbicular; pallial impression simple; animal oblong, its mantle freely open in front with the body and the anterior part of the mantle not furnished with spiny tubes posteriorly; a single siphonal orifice, none foot; very large, strong, and broad, furnished with a byssal groove. Such are the characters of this somewhat unsatisfactory genus as given by Forbes and Hanley. They enumerate three species as British—M. ferruginosus, M. allecincta, M. subtrigassa.

MONTAGU, BASIL, Queen's Counsel, was born April 24, 1770, in London. He was a natural son of John Montagu, 2nd Earl, who had been brought up in the house. His mother was Miss Ray, who was slain in 1779 in the Piazza of Covent Garden, by the Rev. Mr. Hackman, who had fallen in love with her, and destroyed her in a fit of jealous frenzy. Basil Montagu received his early education at the Charterhouse School, London, of which the Earl was a member. He was afterwards sent to the University of Cambridge, where he was soon distinguished for his love of literature, and where he remained till after he had taken his degree of M.A. His father died in 1792, leaving him a competent income, of which he immediately availed himself. He was educated to the study of Chancery. Having selected the law as a profession, he entered himself of Gray's Inn, where he was called to the bar in 1798, but some years afterwards he became a member of Lincoln's Inn. He had set himself up as a tutor, and lived in an intimacy with Coleridge and others of that literary connection, and became so zealous a convert to the opinions of Godwin that he had serious thoughts of relinquishing the profession of a lawyer, as 'injurious to society in proportion to the power and attainments of the individual'. He was Mackintosh, however, with whom he travelled for some years on the Norfolk circuit, convinced him that the doxa of Godwin was not founded in truth, and he continued in the legal profession. He never rose to eminence as a pleader, but having devoted his attention chiefly to the bankrupt laws, acquired a high reputation and good practice in that department.

His first work was 'A Summary of the Law of Set-off, with a State of Cases argued and determined in the Courts of Law and Equity upon the Subject,' 8vo, 1801. It had not appeared many weeks before it was noticed with approbation by Sir Vicary Gibbs, who thus extended the practice of the young lawyer. His most important legal work was 'A Digest of the Bankrupt Laws, with a Collection of the Statutes, and of the Cases argued and determined in the Courts of Law and Equity upon that Subject,' 4 vols. 8vo, London, 1805, 2nd edition, 1819. This 'Digest' became the standard work, and many other editions of it were published. He published also 'Law and Practice in Bankruptcy,' 2 vols. 8vo, with 'Supplement,' 1 vol.; 'The Law of Partnership,' 8vo; and 'The Law and Practice of Partnerships,' 2 vols. 8vo, by W. Johnson Neale, 8vo, 1830. His other legal works and compilations, partly in his own name, partly in conjunction with others, are too numerous to be quoted. Lord Erskine, during his brief tenure of the office of first chancellor (1806-7) made Mr. Montagu a commissioner of bankrupts. While holding this appointment, and deriving a considerable income from it, he became so convinced of the delay and expense to suitors of this mode of administering the law, that he published a yearly detail of these injuries to the public, together with a demand to Parliament for a Committee of the House of Commons, finally put an end to those commissionerships. A new law was made (1 & 2 Wm. IV. c. 80), under which three judges constituted a Court for the trial of bankrupts. This was similar to those previously exercised by the commissioners under the great seal. Mr. Montagu was very much dissatisfied with the new law, but he accepted the office of accountant-general in bankruptcy, which he held during ten years. While in this office he demanded from the government of the Bank of England interest for the bankruptcy money in their possession, which had never previously been paid. His demand was at first resisted, but ultimately he obtained 80,000.

The works and compilations by which Mr. Montagu is best known to general readers are the following:—Selections from the works of Taylor, Hooker, Hall, and Lord Bacon, with an Analysis of the Advancement of Learning,' 1801; 1805. The analysis is carefully executed, and very useful for those who wish to study Lord Bacon's treatises. 'The Opinions of different Authors on the Punishment of Death,' 3 vols. 8vo, 1809-13. In furtherance of these 'Opinions', he prepared a book, entitled 'The diffusion of knowledge upon the punishment of death.' His efforts for the abilities of hanging for forgery and other crimes without violence, in conjunction with those of Sir Samuel Romilly, Mr. Wilberforce, and others, were at length rewarded by complete success, and the Death Penalty to the Edinburgh Times was abolished by a Water-Drinker,' 8vo, 1814. 'The Works of Francis Bacon, Lord Chancellor of England,' 16 vols. 8vo, London, 1825-34. This work was commenced while he was at the university by the translation of Bacon's Latin works, in which he was assisted by Archdeacon Wrangham and other...
The 16th volume, in 2 parts, contains Montagu's 'Life of Bacon,' which, though not distinguished by much power of thought or beauty of style, is a useful exhibition of the leading events in the latter part of Bacon's life. Of the manuscript, dedicated to Mr. Joseph Montagu, was in the hands of the writer, and was translated into French. Montagu assisted in the establishment of several mechanics institutions, and frequently gave lectures in them. He seems to have been not only an industrious and useful lawyer, but an honest, liberal-minded, and benevolent man. He was a frequent contributor to the Gentleman's Magazine, and his poems, in France, when the age of thirty-five he had been twice a widower, both wives having died in childbirth, leaving him four children. In 1608 he married the widow of Thomas Skipper, Esq.; with whom he had four children, three sons and a daughter, and his eight children only a son and daughter are living. His daughter-in-law, Miss Ann Skipper, is the wife of Mr. Procter (Barry Cornwall).

H. G. MONTGOMERY. [CALAMAS, S. Z.]

MONTGOMERY, JAMES, was born at Irvine in Ayrshire, where his father was a Moravian preacher, on November 4, 1771. When only four years of age his parents removed to Grace Hill in the county of Antrim, Ireland, where his father continued to labour in the Moravian settlement at Fulneck near Leeds, in Yorkshire, to complete his education, and in 1793 his father and mother went to the West Indies as missionaries, where they died in 1790. At Fulneck the instruction was excellent, but the moment he left school his life flowed on among the habits of his ten years' residence, distinguished himself for nothing but indolence and melancholy. He had taken a fancy for poetry, which was utterly forbidden in the school; he had clandestinely read 'Robinson Crusoe,' which had greatly interested him; and when, on his thirteenth year, some poor imitations of Moravian hymns. Though characterised by his teachers as indolent, he had contrived to procure and read a copy of Cowper's poems, and these he thought he had composed himself, and wrote, on the sand lines, and commenced a serious epic, to be called 'The World,' and this before he was fourteen. He also wrote other small poems; but his teachers, who wished him to become a Moravian preacher, were dissatisfied with his inattention to his studies. In the school-diary of July 3, 1787, it is recorded that, as "J. M., notwithstanding repeated admonitions, has not been more attentive, it was resolved to put him to business, at least for a time." A situation was soon after offered to him, and he accepted it, and was probably not much more attentive there, for it is stated that he continued to write poetry and compose music till June 1789, when he ran away. He had only a trifle of money when he started; but on reaching Wentworth, he procured three guineas, and bought a coat; and gave him a guinea. He then settled for a twelvemonth at Wath-upon-Dearne as assistant in a general shop. The brethren at Fulneck discovered him, and wished him to return; but he refused. He continued in this situation, silent and recluse, but no doubt pondering over thoughts for which as yet he wanted fitting powers of expression. He continued to write, and at the end of the year having sent a volume of manuscript poetry to Mr. Harrison, the publisher in Palmerston-row, London, followed him it followed him Mr. Harrison declined publishing the poems, but engaged him as shopman. In London he led the same solitary and retired life as in the country. His sole amusement was writing, and he is stated to have never entered a theatre, or even the British Museum, to which it might have been thought his habits and disposition would have led him. While in London his first production, a tale in prose, entitled 'The Chimeras,' appeared in 'The Bee,' an Edinburgh periodical published by Mr. John Miller, which he offered to Mr. Lane, of Minerva-press celebrity, who declined it, because the characters swore too much. The novel was never published, but the objection greatly hurt the religious feelings of Montgomery, who thought he had only imitated'>
his acquaintance. In 1825, as we have said, he resigned the editorship of the 'Iris,' on which occasion a public dinner was given to him by the inhabitants of Shefield, and funds were subscribed to establish a missionary in Toeburg, where his parents had died, the town of which he had named Montgomery. When released from his constantly required attention to the newspaper, he took a lively interest in municipal affairs, and was a frequent speaker at religious meetings. In 1833 he delivered a series of lectures at the Royal Institution on 'History of English Literature,' a subject on which he was not well qualified to speak, and which therefore fell somewhat dull and flat. Later in the year he published 'A History of Missionary Enterprise in the British Colonies,' to which he was himself a contributor. A work of great interest and value. In 1833 he reluctantly declined the office of Professor of Rhetoric in the University of Edinburgh; and in the same year a pension of 150l. was bestowed on him by the Glasgow University. He was knighted in 1836, after having lived forty years in the house occupied by his old employer, Gales, with three of Gales's daughters, who kept the bookseller's shop, on the death of one of them he removed to the remaining two, to a more convenient residence; and in the same year he delivered a course of lectures 'On the British Poets,' at Newcastle-on-Tyne; and for some years added to his income by delivering similar courses at other places. In 1841 he visited Scotland on a missionary tour. He received everywhere with great distinction, particularly in the north of England, where he met with the greatest public reception, and was made a burgess. In 1842 he visited Ireland on a similar errand, saw his old abode at Gracehill, and while occupied in these religious labours often observed being boarded on the ship without. In 1852 he delivered a lecture 'On Some Passages of English Poetry but little known,' but was so feeble as greatly to excite the compassion of his audience. On April 30, 1854, he died; and on the day of his burial the shops and manufactories of Shefield were closed, as all classes, many members of the municipality attending the funeral, as also did the vicar of Shefield and twenty-four clergymen. By his will he left 900l. to be distributed to various charities. His memorials have been collected in seven octavo volumes by John Holland and James Everett, to which we have been indebted for most of the facts in this notice.

MONTGOMERY, ROBERT, was born at Bath in 1807. Of his boyish years we know nothing, but he appeared before the world as an author at an early age, conducting in his native city a weekly publication called 'The Inspector,' which had but a short existence. His next publication was 'The Stage-Coach,' dated 1827 in his collected works; and in 1828 he published 'The Age Reviewed; or, a Satire;' an octavo volume, the poem being dedicated to the Deity; it became astonishingly popular, and eight editions are said to have been sold in as many months. In the same year appeared another volume, 'A Universal Prayer; Death; a Vision of Heaven; and a Vision of Hell;' a second edition of which appeared in 1829, dedicated to Sharon Turner, 'Satans' quickly followed. All were successful; and encouraged by this success, and the advice and assistance of Mr. B. Turner and the Rev. W. L. Bowles, he entered himself at Lincoln College, Oxford, with the intention of devoting himself to the Church. He graduated B.A. in 1833, passing in the fourth class, and M.A. in 1838. His residence at the university he provided himself with a new subject for his poetic muse, and in 1831 he produced a poem, with historical notes and engraved embellishments, under the title of 'Oxford,' which, though extremely laudatory, created more ridicule than applause among the members of the university. In 1832 he published 'The Messiah, a Poem, to the Tune of ‘Hallelujah chorus;' dedicated to the Duke of Wellington; and in 1833 'Woman, the Angel of Life.' In 1835 Mr. Montgomery was ordained, and for a time his ministerial labours seem to have nearly superseded his poetic efforts, a small volume containing observations and scenery around his first curacy, Whittington in Shropshire, being published early in 1842. He quitted Whittington in May 1836, and became minister of Percy-street chapel, London; whence he removed, about the beginning of 1838, to St. Jude's Episcopal chapel in Glasgow. Here he continued until December 1842, drawing large audiences; but his preaching excited so much controversy and bitterness of spirit that he resigned the incumbency, and returned to London, where he immediately published 'Luther, or the Spirit of the Reformation.' In October 1843 he delivered his ministrations at Percy-street Chapel, which he continued till his death. He began the publication of a number of prose theological works, the issue of which was continued to 1854. Neither was poetry altogether neglected. Besides some smaller things, he wrote in 1847 a series of 'Meditations upon engraved plates.' The subjects, published by Fisher; 'Sacred Meditations and Moral Themes;' Svo, 1847; 'The Christian Life, A Manual of Sacred Verse,' 12mo, 1849; 'Lyra Christiana—Poems on Christianity and the Church,' 2vo, 1849; 'Loves on Delightful and Distinctive Syllogisms,' 12mo, 1851; 'The Sanctuary, A Companion in Verse for the English Prayer Book,' 1855. On December 3 of this year he died at Brighton, in his forty-ninth year, all his exertions in the cause of religion having been unrecompensed by any preferment in the Church.

That Montgomery's poetical works should have been so successful as they undoubtedly have been, has excited much surprise. As early as 1830 Mr. Macaulay, in noticing a third edition of 'The Omniscience of the Deity,' in the 'Edinburgh Review,' ascribed the poet's success to unblushing paffery. That his works have been most inordinately puffed is certainly true; but no amount of puffery would have carried a poem through twenty six editions (which the 'Omniscience' has) and reached a hundred thousand copies, if it did not contain something, if it did not contain something truly new and original. He may be found in the gravely important nature of the subjects he has generally chosen, and the class, a numerous one, which he peculiarly addressed. This class, rejecting poetry as a merely intellectual amusement, having no interest or affection for poetry, they welcomed him on account of his themes; he was earnest and sincere; and, prejudiced in his favour, to them his turgidity appeared eloquence, his obscurity assimilated to the mysterious, his vagueusness kept him clear from the narrow ministration of doctrine. His themes, though often selected without taste and scattered without fitness, kept attention alive; and as so voluminous a writer it would be scarcely possible not to find some passages containing good thoughts. However, it is only right that we should acknowledge as excellent the object of criticism. As a preacher he drew large audiences, and his services were often a-keel and given in favour of charitable purposes. His style of preaching in some measure resembled that of his poetry; he ranted, was affected, and vague; but his chief appeal was accepted as earnestness, his affectation as refinement, and his vagueusness as a happy generalising. His manners were engaging, and he always acquired the esteem and regard of his congregations, who on more than one occasion gave him substantial marks of their appreciation.

MONTICELLIUS. [MINERALOGY, S. 1-1]

MOORE, THOMAS, was born in Augier-street, Dublin, on the 28th of May, 1779. His father was a small tradesman, but his mother's family were of the higher rank, and he was early placed at school under a Mr. Whyte, who paid much attention to elocution, who was fond of dramatic representations, and in whose school R. B. Sheridan had once been. Moore, a quick and lively boy, became a favourite pupil, and as early as 1770 exhibited his talents in reciting an epilogue at a private theatrical entertainment: other dramatic exhibitions were got up by his parents, for which he wrote epilogues or prologues. When he first began to rhyme, he says, he cannot remember; but in 1790 he contributed two poems to 'The Boy's Own Paper,' and a translation of the 'Legends of Hope,' which were inserted, to his intense gratification. In this year the restrictions which prevented Roman Catholics from studying at the Dublin University were removed, though all honours and offices were still denied them. His mother, who wished him to be a lawyer, induced his father to enter him at Trinity College in the summer of 1794. At college he pursued the usual studies with tolerable success, gaining several marks of distinction, though, feeling an inability to sustain himself without the assistance of the college, he occasionally took some English verses, which were approved of by the judges, and for which he received a reward. He continued also to write verses for the 'Anthology' while it was in progress, and to perform occasionally at the Drury Lane theatre, and to play the piano from his sister's teacher, Italian from the priest of the family, and French from an emigrant acquaintance. In the second year of his college attendance he soared yet higher, and wrote a masque with songs, which was performed in his father's drawing-room.
MOO

Born a Roman Catholic, accustomed from infancy to hear the
wrongs of his fellow-religionists descanted on, influenced by
the teachings of his father, and perhaps by the more generous
son to the pretensions to a scholarship in the university
being unavailable on account of his faith, it is little to be
wondered at that he took a lively interest—though for
himself undemonstrated—when the events occurred in the
plots preparatory to the rebellion of 1798. He
was examined before Fitzgibbon, the vice-chancellor; but as
he could honestly avow himself ignorant of any plot, he
was discharged.

He at length took his degree of B.A., and left the
university, it being necessary in those days to have seen
the so-called odes of Anacreon, a specimen of which he
bought from the provost of the college, Dr. Kearney, with
a hope to obtain a classical premium. Dr. Kearney thought
the translation good, but that the subject was not likely
to be very popular. Kearney and his brothers were
living at the Middle Temple in London, whither he went, scantly
supplied with money, to study law. In London he was in-
truded to Lord Moira, Lady Donegal, and others; he moved
in a fashionable circle; he published in 1801 his Odes
Anacreon; and of course paid little attention to his legal
studies. His next publication, in 1802, was 'The Poetical
Works of the late Thomas L'Ette,' for which he received
60l. They were severely blamed and much read, and their
scoffers were disposed to place them on a level with
his friends, on account of their poetical ability. In
1803, by Lord Moira's influence, he was appointed to a
government situation in Bermuda. In January 1804 he
arrived there, having purchased a property of about 1,000 acres
in Virginia.

He at once found that the situation did not suit him,
and in March he left Bermuda, appointing a deputy to
fulfil his functions. He then journeyed over a part
of America, going from New York to Virginia, and back by
Philadelphia and Boston. The negroes were a special
society in America he was much dissatisfied, and recorded
his sentiments in some satirical poems. In November 1804
he was in England. Here he expected much from
Lord Moira's patronage; but only succeeded in obtaining the
appointment of deputy of the Custom House in Dublin for his
father.

In 1806 he published 'Odes and Epistles,' which being in
a similar style to the Little Poems brought upon him the casti-
gation of Jeffrey. This occasioned a bloodless duel, the
cause of much murmuring at the time, and led to a firm
friendship between the combatants. He was now
leading a life of fashionable excitement among the aristocracy
of England, a visitor to Lord Moira at Donington Park, and a
constant guest at Lansdowne House and Holland House.
Appointed one of the King's Harlots, his attention was
attracted to Bunting's collection of Irish melodies, and at intervals
he had written words for several of them, which he was accus-
tomed to sing himself with much effect. In 1807 he entered
into 'The Fudge Family in Paris,' a series of poetical stories,
and political satires, which was published at Paris in
1808.

In that year he published 'Lalla Rookh,' a composition
of a bloodless duel, the cause of much murmuring at the time, and led to a firm friendship between the combatants. He was now leading a life of fashionable excitement among the aristocracy of England, a visitor to Lord Moira at Donington Park, and a constant guest at Lansdowne House and Holland House. Appointed one of the King's Harlots, his attention was attracted to Bunting's collection of Irish melodies, and at intervals he had written words for several of them, which he was accustomed to sing himself with much effect. In 1807 he entered into 'The Fudge Family in Paris,' a series of poetical stories, and political satires, which was published at Paris in 1808.

In that year he published 'Lalla Rookh,' a composition in the same style. In 1808 he entered into 'The Fudge Family in Paris,' a series of poetical stories, and political satires, which was published at Paris in 1808.

In 1809 he published 'The Sceptic.' They were not very successful. Moore's muse was too sportive, his fancy too playful, his heart too genial, for him to excel in severe satire which he here attempted.

In 1811 he married Miss Bessy Dyke, a truly estimable woman, to whom he ever continued fondly attached, and who was the source of all his parent happiness for the remainder of his life. In the autumn of the same year his opera of 'M.P. or the Whigs' was produced at Drury Lane. It was but moderately successful, ran a few nights, and has never been repeated, though some of the songs, published separately in his collected works (from which the opera is now reprinted), were much admired. Some time after he returned to Paris, where he now made up his mind to live by his pen; he quitted London, and went to reside with his family at Mayfield Cottage, near Ashbourne in Derbyshire, where in 1818 he produced the 'Twopenny Post-Bag, by Thomas Brown the Younger.' The

It was written in this style, the viewpoint of the poet, he was directed against the Prince Regent and his ministers, and made them immediately popular, and fourteen editions went through the press in a twelvemonth.

As early as 1812 Moore had contemplated the writing of an
Oriental romance, and his friend Mr. Perry of the 'Morning Chronicle' stipulated for him with Messrs. Long,
man, the publishers, that he should receive for a quart volume the sum of three thousand guineas: this was agreed to; but it was not till 1817 that 'Lalla Rookh,' at length appeared. It was eminently successful; it has passed through many editions, and it has been frequently translated. It may however be doubted whether it will contribute to his perma-
nent fame. It is brilliant, melodious, in the 'Fire Worship-
ers' it is one of the few poetical romances in which the
characterisation; it is untrue to nature, it is cloying with its
sweetness, it is oppressive with its imagery; the feelings
described are almost uniformly sensuous, and the art of the
poet sometimes divides his poetic gifts to the advantage of
the prose of 'Lalla Rookh,' he made a trip to Paris in company
with Mr. Rogers, and this enabled him to produce
'The Fudge Family in Paris,' a series of poetical epistles, an
entertaining collection of satirical remarks on character
and politics, which was published at Paris on the 12th of
August 1804. In 1817 he lost one of his children. Early in 1818 he learned that his
deputy in Bermuda 'after keeping back from me the paper
receipts of my office,' he wrote in his letters "that now, it seems, made free with the proceeds of a ship and
cargo deposited in his hands, and I am called upon by a
motion from Doctors' Commons, to be accountable for it." The
claim was for about 600l., of which little was hoped to be
recovered from the deputy. On this occasion his friends
flocked round him with offers of assistance, but he declined
receiving any, as he preferred paying the money, whatever
it might be, by the earnings of his pen. In 1819 he
accompanied Mr. Rogers on his journey to Italy, visiting
Chantrey the sculptor, and Jackson the painter. This expedition was
recorded in 'Rhymes on the Road,' published together with
'Fables of the Holy Alliance.' 'The Sceptic' had been sent to be 'extracted from the Journal of a Travelling Member of the Poococurate Society,' and are serious, political, artis-
tical, and satirical by turns. As the law proceedings
respecting the defalcations were still pending, he did not return
to England but, setting for his family, took up his abode
at Paris, where he continued until 1822. He purposed
to work hard; but the gaiety of the place, the interruption of
visitors, and probably anxiety as to his ultimate loss,
prevented his carrying his intentions into full effect. He
entered into an engagement to write a life of Sheridan; but
in Paris he found himself, or thought himself, so unfur-
nished with materials, that he gave it up and 'The Loves of
the Angels,' a poem, issued in 1823, and the prose-poetical
'The Pirate.' In 1824 he left France, and was in the
possession of only additional works produced during his residence abroad.

The claim with regard to the Bermuda defalcation had by
this time been settled by Mr. Moore's friends in London,
heaving been reduced to 400l., which was paid by a cheque
from Lord Lansdowne, and repaid by Moore, chiefly from
the proceeds of his 'Loves of the Angels' and his 'Fables of
the Holy Alliance.' He now settled at Sloperton Cot-
tage, near Bowood, the residence of the Marquis of Lans-
downe; and there he composed and published 'The Pirate.' He
at once began in earnest his 'Life of Sheridan,' which was
published in 1825. In 1827 'The Epicurean' was
published, with some fragments of a poem called 'Alciphron,'
on the same materials.

Before he left Paris Moore had presented Moore with his
manuscript autobiography, for his special benefit, but not
to be published till after his death. In this year, in order

3 K 2
To raise money, Moore had sold it to Mr. Murray, with an express condition that he edit it, for 2000 guineas; and the manuscript was assigned to, and deposited with him, in April 1834. In this month Byron died; and on the news reaching England, Moore was anxious to redeem the manuscript, which he considered he had a right to do; Lady Byron and the family were disinclined to publish it just at that moment, and in any case they considered its publication would be alike hurtful to their feelings and injurious to the character of his Lordship, and offered to repay Mr. Murray the sum he advanced. Moore refused to accede to this; he was willing to defer to their feelings, to suppress or alter what was unfit to be made public, or even to burn it if competent persons should decide that its publication would be improper; but insisted that in any case he alone should be the loser. After a long and unpleasant conference, he was repaid the money he had advanced to Mr. Murray, the manuscript was burned, and he engaged for the like sum to write a 'Life of Lord Byron' for the Messrs. Longman. This he did, but ultimately the copyright was transferred to Mr. Murray, by whom it was published in 2 vols. 4to in 1839. In 1831 he wrote 'The Life of Lord Edward Fitzgerald; and 'The Summer Fête,' celebrating an entertainment given at Boyle Farm in 1837. To this followed 'The History of Ireland,' which appeared in 'Larrikin's Almanack' in successive volumes. This was his last work of importance. In 1835, during the administration of Lord Melbourne, a pension of 300l. a year was bestowed on him by the Queen as a reward for his literary merit. It was bestowed in good time: he had become unwell and was not only poor and retired, but bereaved. He was distressed by this, and on hearing the news, his two sons, one died in Algeria in the service of the French, the other died of consumption in 1842. In 1841 he commenced an edition of his collected poetical works, including the scattered pieces with which he had enriched almost every newspaper and magazine of the metropolis, and which they were issued in ten monthly volumes. For the last three years of his life he was afflicted with a softening of the brain, which reduced him to an imbecility, though without pain, during which the sedulous attention of his wife was most exemplary. He died on the 22nd of February 1852, and was buried in the churchyard of Bromham, near Devizes.

Of Moore's critical genius we have already spoken. To his prose there is less to be given. His biographies, with many sparkling passages, are all faulty, diffuse, and uncharacteristic. His 'History of Ireland' is his best work, as it is an interesting and careful production, though not an impartial one.

Moore's character in many respects was truly estimable. His affection for his parents was unflagging and indestructible: he carried him in early life safely through the second condition of fatherhood, as he would commit no extravagance that might require him to run into heavy expenses; it induced him to postpone his own hopes of official advancement to the provision of a small place for his father, and of the 300l. received for 'Lalla Rookh,' 2000l. was applied to the establishment of a pension for his mother and his parents. To his wife and family he showed the fondest attachment, and it was duly reciprocated. He had been urged against him that he too often left his wife in solitude while he was thronging in fashionable circles; but it should be remembered that he believed numerous of his fame, and consequently his fortune, depended on his keeping himself well before that world which alone could become purchasers of the expensive quarters in which shape his works first appeared; nor was there any doubt that even in the humblest of his circles he was always avowed himself proud of his wife, introduced her to all his aristocratical friends, and frequently urged her to mix more with them, which her native good sense made her desire as much as possible, while she ever willingly submitted to those abstinence she considered useful to their mutual interests. As a friend he was faithful, kind, and generous; and he secured the esteem of many of the most eminent men of his day. As a politician he was consistent in his principles, though he was not always right or always unchangeable in his opinions. He was vain yet few men have had so much pains taken to make them so, petted as he was from his boyhood till old age withdrew him from the world, and his vanity was harmless and never obtrusive. The strongest proofs of his humility were given in his last known publication after his death in the 'Memoirs, Journal, and Correspondence of Thomas Moore,' by Lord John Russell, in 1863-35, in 8 vols.

MORACEAE, a natural order of Exogenous Plants which were formerly placed as a sub-order of Urticaeae. The species are trees or shrubs, with a milky juice, sometimes climbing. The leaves are commonly lobed and rough. The flowers are small, monocious, and collected in heads, spikes, or catkins. The ovules are solitary and suspended. The fruits are capsules, burs, or nutlets. In the middle of fleshy albumen, hooked, with the radicle long, superior, folded down towards the cotyledons.

Although the Mulberry and Fig grow in Europe, all the Moraceae are extratropical. They are natives of the temperate and tropical latitudes of both hemispheres, often forming vast forests. The genus Ficus is the most distinguishing feature of this order. [Ficus.] Most of the plants of this order furnish caoutchouc. [Cauuoucnc.] The fruit of the 'Breadfruit,' or 'Sugar-apple,' is a good article of food; the leaves of the Silk-Worm. [Moou.] Several species of Derronia are used in medicine. [Derronfia.] Other genera of this order yielding useful products are Broussonetia and Maclura. [Broussonetia; Maclura, S. 2.]

This order embraces 8 genera and 184 species.

MORCHELLA, a genus of Fungi, one of the species of which is eatable. [M. esculenta, the Morel, springs up in orchards, woods, and cinder-walks, early in the spring and eats the young green fruit. Common Morchella is a species of the same genus that has been found in forests where fir trees have been made. The country people in Germany are so persuaded of this, that they formerly set fire to woods in order to obtain a crop of morêls, of which they are very fond. At last the practice was put down by law. This fungus has a thick, yellowish subperitical cap, from the size of a pigeon's egg to that of a swan's, hollow, pale-brown, or even grey, and deeply pitted all over its surface, the depressions being separated by raised ascomatining lines. The plant is a small, slightly and an agreeable taste, and is employed for various purposes of both fresh and dried. In the former state it is most commonly stewed or stuffed with force-meat; in the latter it is employed as an ingredient in sauces. In this country it is of rare occurrence.

MOREL. [Morchella, S. 2.]

MORETON BAY. [Australia, S. 2; Wales, New South.]

Moringaceae, small natural order of Exogenous Plants, embracing the species of the genus Moringa. They are characterised by the possession of a many-leaved caïy, perigynous petals and stamens, 1-celled anthers, stigmate and consolidated siliquose fruit, and seeds without albumen. This order is referred by most botanists to a position near Leguminosae, but Lindley places them in his Phloxidae. They are natives of the East Indies and Arabia. The root of Moringa pterygosperma has a pungent odour with a warm biting and somewhat aromatic taste. The seeds contain rich substances, and are used by the Chugees and Chicot. They are the Ben-Nuts of old writers, from which the Oil of Ben was extracted. It is chiefly used by perfumers as the basis of various scents. It does not readily dissolve in water. The uses to which this oil is applied on this account is used by watchmakers. The flowers, leaves, and other parts of this plant are added to curries in India.

Mormons. [Smith, Joseph, S. 2; Utah, State of, S. 2.]

Morphology is that branch of science which treats of the laws which regulate the forms assumed by Plants and Animals. When this term was originally introduced into natural history science, its application was confined to the explanation of the changes which occur in the conversion of the less into the parts of the flower in plants. It is now however generally recognised as the science of form in the organic kingdoms. Schleiden, in his Principles of Scientific Botany, treats of what is usually called the structure of plants, under two heads, that of General and Special Morphology. The following are his definition and remarks upon this subject.—

'Morphology is the study of the forms of plants, and of their several parts. It is divisible into a general branch, which deals with the parts as the union of the parts and the organs in general, and a special branch, which treats of plants according to their principal groups, as well as their individual organs; and this latter branch again is separable into one that treats of the delimitation of external form, and the delimitation of internal structure of the peculiar composition of plants and their parts from various tissues.
widely distant members have perhaps no element identical, if we would attain to scientific knowledge, if we would understand nature, and not merely acquire a disjointed, uncomprehended, and incomprehensible acquaintance with it. In these considerations it follows, setting the paramount importance of the morphological method of observation, that we gain nothing by the comprehension of the forms compared, but that the method of morphological development, and direct our scientific inquiries, not to an individual complete at any one period, but to the comprehension of the collective constant series of normally changing forms. The conception of genera and species in the unchanging form is the result of a comparison but also of a connection of the various individual characteristics with each other. In this manner we should lay a firm foundation for the inductions to lead us to a theory of organic physiology, if we could but succeed in completing the theory of the formation of inorganic forms.

As yet we are far from this point, and simply because it is only in the most recent times, and yet very imperfectly, that the importance of the study of the history of development has been acknowledged. Although without this, botany would be wholly divested of all scientific principles. This deficiency renders it impossible as yet to treat morphology with scientific logical development, or in accordance with a perfectly fitting mode of arrangement, as will but too obviously appear in many manœuvres, although the blame of this is only partially to be imputed to me. It seems however practicable perfectly to state the problem, and to this end I subjoin the following remarks:

1. We have just seen that the individual is the foundation, and to delineate the forms themselves. The first remains for the present a mere problem, the solution of which must be reserved for succeeding times. The second may be accomplished, although imperfectly. I say imperfectly, because, instead of those series of forms which we ought alone to treat, we only know a few individual conditions; and therefore the greatest portion of the task still lies unperformed before us. Here we must again return to Seguin’s doctrine of organic development, especially when we must enter upon all possible construction in a very different way from what has hitherto been done. For this purpose we must consider somewhat more exactly the characteristics of organic form, especially the vegetable, as opposed to the inorganic. The inorganic form, the crystal, is permanent when once formed; it is unchangeable; the individual (the individual existence) is the form itself, and by its solution and change of form a new individual arises. It is in consideration of this that we must accept the permanence and the change of the form, as permanent, but an ever-changing one. The analogies between the two hold good only in the simplest cases. The nucleus of a crystal originates in a definite form, and then passes through a series of forms, until it reaches the deduced or hypothetical form, and then continues to change, until the individual is destroyed with the form. Thus certainly it has a very simple history of development, but this continues merely so long as something is still being added to that which is already present, until the whole is completed. The cell is formed in a manner somewhat analogous to this, originating in a definite form, and passing through a series of changes, which, as it appears, only contribute new matter until the form is complete; this then remains stationary until its solution and the consequent destruction of its individuality. It is however wholly different in combined forms, and these it is which, with few exceptions, compose what we term plants. Here a number of cells combine together within definite external limits; but these cells themselves do not enter into the form as dead particles of the mass; they continue to develop new cells, whilst the old ones are partially destroyed: the newly originated cells change, by their arrangement, the form of the whole, and, since formation of new taken as an end; it is at last; but in the conception of which we must comprehend the whole series of changing forms, wherein the
of North America in 1798. His parents were members of the Society of Friends, and he had the misfortune to lose his father early in life. His mother however married a second time when young Morton was thirteen years old, and from his step-father he seems to have derived a liking for the study of natural history. Mr. Morton was in the habit of going in a counting-house, but his taste for natural science led him to abandon business and enter the medical profession. He was accordingly placed with Dr. Joseph Parrish of Philadelphia, who, although unconnected with any public medical office, gave him a good hand in the management of his laboratory, and education of young men studying the medical profession. He attended the lectures and passed through the course of instruction prescribed for the students of medicine in his native city. He was graduated M.D. in March, 1820. He was at the same time admitted a member of the Academy of Sciences (Philadelphia). Soon after this he sailed for Europe, and, after visiting an uncle—Mr. James Morton of Clonmel, in Ireland,—he repaired to the University of Edinburgh. Here he studied two years, and graduated in medicine in 1823. His inaugural thesis was entitled, "Tentamen inaugural de Corporis Dolore." During his period of preparation for graduating in Edinburgh he visited France and Italy, and made a stay in Paris. He returned to America in 1824, and in 1825 in time to witness the departure of some of the most eminent literary and scientific men in Philadelphia to join in the illustrious social experiment of Dr. Robert Owen at New Harmony. Morton became an active member of the Academy of Sciences, and commenced his contributions to its transactions by a geological paper. It was entitled, "Analysis of Tabular Spar from Bucks County." He subsequently contributed many papers on Geology and Palæontology. One of the most important of these papers was published in a separate volume entitled, Synopsis of the Organic Remains of the Cretaceous Group of the United States. This was a very valuable contribution to Geology, and was received with the warmest commendations by European geologists. He cultivated generally the natural history sciences, and wrote several papers on zoological subjects.

While pursuing natural history with success, he did not neglect to keep up the transactions of the Academy. In 1834 he published a work entitled "Illustrations of Pulmonary Consumption; its Anatomical Character, Causes, Symptoms, and Treatment." He also edited an edition of Dr. Macintosh's "Practice of Physic," with notes and additions. From 1839 to 1843 he filled the chair of anatomy in the medical department of Pennsylvania College. In 1840 he published "An Illustrated System of Human Anatomy, Special, General, and Microscopic." His previous labours, however, were but preparations for the great works on which his reputation as one of the first ethnologists of his day is founded. The line of his research on the races of men lay more particularly in their anatomical constitution, and especially in the structure of the skull. During his researches, he amassed collections of skulls and extant, and is now in the possession of the Philadelphia Academy of Practical Sciences. The origin of this collection may be given in his own words:—"Having had occasion," he says, "in the summer of 1830 to deliver an introductory lecture to a course of anatomy, I chose for my subject 'The different Forms of the Skull as exhibited in the Five Races of Men.' Strange to say, I could not procure for me a cranium of each of these races, and all I had at command was a Malay, an Australian, and one from the Malay or the Malayan. Forcibly impressed with this great deficiency in a most important branch of science, I at once resolved to make a collection myself." The result of this determination was not only his great collection, but the two magnificent works, entitled ''Crania Americana, and' ''Crania Egyptica.' These works embraced not only an account and illustrations of the skulls, but general ethnological observations on the races of men. The collection on which these works were founded is 631 of the largest and best prepared from all parts of the world, 278 crania of mammals, 321 of birds, and 68 of reptiles and fishes.

Although in his earlier writings he maintained the specific unity of the human race, in the latter part of his life he was led to doubt this view, and to express the opinion of the existence of a diversity of species among men. This view has been strongly insisted on, in a work published since his death, under the title of "Types of Mankind." This work, edited by Messrs. Nutt and Gliddon, contains a large mass of matter by the editors and others, with many "Excerpts" from Morton's inedited papers. In these he undoubtingly avows his belief in an "aboriginal plurality of races," and expresses his conviction, that "man will yet be found in the fossil stage as he is in the Eocene deposits, and that he walked the earth with the megalycon and palaeotherium." It is only right to add that these views have not been generally received; and that our most distinguished ethnologists, palæontologists, and geologists have not endorsed his more recently enunciated views. Mr. Morton died at Philadelphia, after a short illness of five days, on the 17th of May, 1851.

MOSANDERITE. [MINERALOGY, S.1.] MOSQUITO. Following is an account of the structure of the Mosquito of the Americas, by an American observer:

"The male mosquito differs considerably, as is well known, from the female; his body being smaller and of a darker colour, and his head furnished with antennæ and palpi in a state of greater development. Notwithstanding the fitness of his organs for predatory purposes he is timid, seldom entering dwellings or annoying man, but restricts himself to damp and foule places, especially sinks and privies. The female, on the other hand, gives greater extension to her paws, her antennæ, and her mouth parts, in order to cause the incon siderable disturbance and vexation during the summer and autumn months.

"The head of the male mosquito, about 0.67 mm. (milli metres) in length. The eyes, which are disposed in front superiorly are found two pyriform capsules nearly touching each other, and having implanted into them the very remarkable antennæ.

"The capsule, measuring about 0.91 mm., is composed of a horn-like substance, and is attached posteriorly by a pedicle, while anteriorly it rests upon a horn ring, united with its fellow by a transverse frenulated band, to which it is joined by a thin elastic membrane. Externally it has a rounded form, and is internally cumbers a certain sort of lamp-shade with a constricted near its middle; and between this inner cup and outer globe there exists a space, except at the bottom or proximal end, where both are united.

"The antennæ of are of nearly equal length in the male and the female.

"In the male the antennæ is about 1.75 mm. in length, and consists of 14 joints, 12 short and nearly equal, and 2 long and equal, terminal ones, the latter measuring together 0.70 mm. Each of the shorter joints has a fenestrated skeleton with an external investment, and terminates simply posteriorly, but is encircled anteriorly with about 40 papules upon which are implanted long and stiff hairs, the proximal sets being about 0.70 mm. and the distal ones 0.70 mm. in length; and it is beset with minute bristles in front of each whorl.

"The two last joints have each a whorl of about 20 short hairs near the base.

"In the female the joints are nearly equal, number but 13, and form a sort of a whorl of about a dozen small hairs around the base. Here, as well as in the male, the parts of the antennæ enjoy a limited motion upon each other, except the basal joint, which, being fixed, moves with the capsule upon which it is implanted.

"The space between the inner and outer walls of the capsule, which we term conveniently the auditory capsule, is filled with a fluid of moderate consistency, opalescent, and containing minute spherical corpuscles, and which probably supply the auditory organ with a fluid nourishment. The capsule is about 0.23 mm. in length, containing five teeth belonging to the incisors. These teeth are divided into two portions. The central teeth continue forwards into the antennæ and are lost there; the peripheral ones, on the contrary, radiate backwards in every direction, three being in the cranial space, and are lodged for more than half their length in sulci wrought in the inner wall or capsule.

"In the female the disposition of objects is observed to be nearly the same, excepting that the capsule is smaller, and the teeth of the cranial joint are reduced to one. The female proboscis does not differ materially in the two sexes; but the palp, although consisting in both instances of the same number of pieces are very unlike. In the female they
are extremely short, but in the male attain the length of 2-73 mm., while the proboscis measures but 2-16 mm. They are curved upwards at the extremity.

"If an organ of hearing, similar to that described by Tre-
virius as belonging to the Blattia orientalis, exist in the head of the M. diabolus, the tympanum must be of extremely
minute proportions, because the head, which has a diameter
of only 0·67 mm., is almost entirely occupied by the corneal
plaque, the capsules, and the attachments of the neck and
of the buccal apparatus. The membranes tympanic must
then be reflected inwardly, for the organ to be really held
in vibration by any sounds other than those infinitely more
acute than are produced by the insect itself, and the use of
such an organ for the purposes of intercommunication must
be considered highly improbable. Such an organ is to be
found in the head, nor very certainly, also, in the body;
and we are obliged to look for some organ which may
answer the requirements of an effective auditory apparatus.

The position of the capsules strikes us as extremely
favourable for the performance of the function which we
assign to them: besides which there present themselves
in the same light the anatomical arrangement of the capsules,
the disposition and lodgment of the nerves, the fitness of the
expanded whorls for receiving, and of the jointed antennae
for directing them. The whole appears as the result of
modulations created by sonorous modulations. The intra-capsular
fluid is impressed by the shock, the expanded nerve appreci-
ates the effect of the sound, and the animal may judge of
the duration and quantity of the impression; of the pitch, or quality, by
the consonance of particular whorls of the stiff hairs, according
to their lengths; and of the direction in which the modula-
tions travel, by the manner in which they strike upon the antennae,
in consequence of an opposite movement of that part.

"That the male should be endowed with superior acuteness
of the sense of hearing appears from the fact, that he must
soon see the female, for the tympanum either in the dim light
or in the dark night, when nothing save her deep sharp
humming noise can serve him as a guide. The necessity for
an equal perfection of hearing does not exist in the female;
and accordingly we find that the organs of the one attain to
a development which the others never reach. In these views
we believe ourselves to be born out by direct experiment,
in connection with which we may allude to the greater dif-
culty of catching the male Mosquito.

In the course of our observations we have arrived at the
conclusion that the tympanum is of considerable extent,
as organs of touch in the female; for the palpi are extremely
short, while the antennae are very movable, and nearly
equal the proboscis in length. In the male however the length
of the antennae are far greater, and we cannot look for the seat of the tactile sense elsewhere; and in fact
we find the two apical antennal joints to be long, movable,
and comparatively free from hairs; and the relative mo-
tion of the remaining joints very much more limited." (Dr.
Christopher Johnston, Quarterly Journal of Microscopical
Science.)

MOTACILLA, MOTACILLINÆ, [BLUE BIRD; BLUE
BEAK; SYLVIA; WAGTAIL.]

MOTELLA, a genus of Fishes belonging to the family
Gadidae. It has the following characters: Body elongated,
cyindrical, compressed posteriorly, the first dorsal fin very
slightly elevated, delicate in structure, scarcely perceptible;
second dorsal and anal fins long, continued nearly to the
base of the tail.

M. vulgaris, Mustela marina (Rays), Gadus trique- tratus
(Bloch), the Three-Bearded Rocking, Sea-Loche, Whistle-
Fish, Three-Bearded Cod, Three-Bearded Gade, has the
following characters: The length of the head compared to
the length of the body alone, without the caudal rays, is as one
to four; the depth of the body equal to the length of the
head; the first dorsal fin delicate in structure; the first ray
elongated, the rest hair-like; the second dorsal fin commences
along the back to the tail, being partly visible when the fish is
along the back to the tail, but ending a little shot of the
base of the caudal rays; ventral fins with the first two rays
elongated, the second most so, the two distinct; the other
five rays nearly equal, united, and short; pectoral fins rather
large, horizontally prolonged, reaching nearly to the anal
fin. Black, with a brown edge on the head, the back of the
chin and the end of the fleshly portion of the tail; the anal
fin commences immediately behind it, is one-fourth less
in length than the second dorsal, and ends on the same plane
with it; the tail moderate in size, and rounded at the end.
The fins rays in number are—2nd D. 55; P. 20; V. 7; A. 49;
C. 18. The head is depressed; the mouth wide; the jaws
nearly equal, but when separated the lower jaw is the longer,
with one barbule at the chin; a mixture of large and small
eyes in each; the inner eye has a white ring, the outer
side the middle, between the lip and the nostril; inner part
of the upper lip crenate; the ridges golden yellow; the
anterior portion of the body of the fish cylindrical, or slightly
depressed; the tail compressed; the general colour of the
body and head is yellow, with silvery brown, spotted on the top of
the head, along the back, the pectoral, dorsal, and caudal
fins, with rich chestnut-brown; the lower part of the sides,
the ventral and anal fins pale yellow-brown approaching to
white, and the anal while.

Young fish of this species are of a uniform brown colour,
until they have acquired 6 or 7 inches in length; in this
condition they are the Mustela alia of Ray. (Yarrell.)

This fish is common on the coasts of Cornwall, and also
on the coasts of Ireland.

M. cinerea (Gadus cinereus, Linnaeus), the Four-Bearded
Rocking. This fish has been taken in Scotland, and is
common in the Baltic and the southern coast of Sweden.

M. quadrivittatus, Brunni (Gadus quadrivittatus, Linnaeus),
the Five-Bearded Rocking. This fish is common in the
British coast. Its habits resemble those of the Three-Bearded
Rocking, and by some naturalists it is regarded as a variety
of that species.

M. planiceps (Ciliata glauca, Couch), the Mackeral Mides.
This fish has been taken on the coasts of Cornwall by Mr.
Coush. It dies instantly on being taken out of the water.
It is like the young of some of the other species, but it
has not been observed to grow.

M. argenteolus, (Montagu), the Silvery Gade. This
fish is a miniature representative of the Three-
Bearded Rocking, as the last is of the five-bearded species.
It was first described by Montagu, and is admitted as a
distinct species by Yarrell.

MOULMEIN, a town and port in the Tenasserim Pro-
vinces, which form a part of the British possessions on
the eastern side of the Bay of Bengal. Moule in is situated
north of the mouth of the river Salay, at the confluence of the
rivers Salay, Aitven, and Yang, in 10° 20' N. lat., 97° 44' E.
long.; the three rivers when united are called the Moule in
River. It is 10 miles S. by E. from Martaban, and 30 miles
N. by E. from Amherst. (Amherst.) Moulen has a good
harbour, which admits vessels of 600 or 800 tons. Being
secured from temporary disturbance of the French, who
import and export, it has drawn away much of the commerce
which belonged to Martaban, and has in a great measure
superseded Amherst. The population is estimated at upwards
of 10,000, consisting of Chinese, English, Dutch, tintorers, rice, tobacco, ivory, stick-lace, cocoa-nuts, and live-stock. The imports are cotton
goods and other manufactures.

MONTMELlick. [Queen's County.]
MOUNTRATH. [Queen's County.]
MUCIC ACID. [Chemistry, S. 1.]
MUCORACEÆ, an order in Lindley's alliance Fungales.
The species have a fleshy thallus and the spores surrounded
by a vesicular veil or sporangiurn. They are amongst the
smallest forms of Fungi, and attack decaying vegetable and
animal matters. They are frequently known by the name
of Moulds. (Mouldness; Fungi; Entophila, S. 2; Moulds.)

MUDARIN. [Chemistry, S. 1.]

MUDGE, WILLIAM, LL.D., F.R.S., a major-general in
the army, the third in succession of the directors of the
series of geodetical operations, which resulted in the
Triangometrical Survey of Great Britain and Ireland, the
production of the 'Ordnance Maps' by its means, and the
measurement of the English Arco of the Meridian. The
history of family and hereditary talent, and the occupation
of certain offices by a succession of gifted men, have
frequently been illustrated in this work. They are again
briefly touched upon by Mr. J. G. Cooper, in his Rev. ZACHARY MUDPUS, sometime master of the Grammar
School at Bideford, in Devonshire, and vicar of Abbotsham,
afterwards a prebendary of Exeter and vicar of St. Andrew's,
Plymouth, was the author of an "Essay for a New Version
of the Psalms," and the same year was nominated Member of
the Royal College of Physicians, being elected by the
volume of sermons published in 1727. He died April 3rd, 1769, and
was eulogised by Dr. Johnson, whose intimate friend he had
been. THOMAS MUDUS, his second son, born at Exeter in

Digitized by Google
1716, was apprenticed to the celebrated watchmaker, George Graham, and became himself one of the most eminent mechanists of his time: a select committee of the House of Commons, assisted by a committee of men of science, philosophical instrument makers, and watchmakers, including Atwood, Ramden, Troughton, and De Lucy, declared in 1757, that he was one of the first watchmakers which this country has produced. In consequence of a report made by the select committee, a reward of 3000l. was granted by parliament for his invention and perfection of asteam engine. In 1760, a mile, were first produced under Mudge's superintendence, and were issued from time to time (after an interval during the war, in which they were withheld from publication), at the highest value in reference to the topography of the country.

Whilst General Mudge was superintendent, but by the personal exertion of Captain Colby, the principal triangulation of the survey was extended, as just indicated, to the north-western tract of the British dominions, as it had been carried on under his orders in former years, his successor had to correct errors and supply many omissions. These, as we are informed by competent authority, had resulted from the hurried manner in which the work was performed, from the very imperfect maps placed at General Mudge's disposal, and from the want (since supplied) of a legislative enactment for the preservation of the various trigonometical observing stations throughout the country, which want sometimes led to a transfer of the points to the care of levelling officers, to the prejudice of the survey; so that, all things taken into consideration, it is rather to be wondered at that the work should, generally speaking, be so good as it is known to be.

(Mem. Roy. As., vol. XIII., p. 31.)

General Mudge was afterwards appointed lieutenant-governor of the Royal Military Academy at Woolwich; into the administration of which he is stated to have introduced many excellent regulations, which were afterwards extended, and adopted by the cadets of the East India Company at Addiscombe. In addition to the public employments and distinctions which have been mentioned, he was a member of the Board of Longitude, a Fellow of the Society of Antiquities, a member of the Geographical Society, and Honorary LL.D. of the University of Edinburgh. The Royal Academy of Sciences of Paris elected him a correspondent, and the Academy of Sciences of Copenhagen, a Fellow. He died at his house in Holles-

street, Lidcombe, on the 7th of April, 1821, in his fifty-eighth year, leaving a widow, with three sons and a daughter.

Of one of the sons, Richard Zachary Mudge, who entered the army in 1807, and served in the Peninsula, became eventually a lieutenant-colonel in the royal engineers and P.R.S. He also was attached to the Trigonometrical Survey, in which, after Captain Colby had been appointed superintendent, he was entrusted for some years with the local business of the Trigonometrical Survey of Belgium, where the results of the Survey were laid down, and the maps actually constructed—during the absence of his chief on other duties. He afterwards retired from the service, and entered into business as a banker in Devonshire. He died at Steighnagh on the 24th of September, 1854, aged sixty-five.

MUDWORT, the common name of the species of the genus Limosella. This genus belongs to the natural order Scrophulariaceae. It has a 5-cleft calyx; a 5-fid bell-shaped corolla; a globose, papillate capsule, with a central placenta, free, or connected with a short dissepiment below, 1-celled. L. aquatica is only British species. It has lanceolate leaves, which are toothed, and pedicel axillary, concealed; shorter than the pedicels. It has small white or rose-coloured flowers. It is found growing in muddy places, where water has stagnated.

MULET. [Moolids; Mulds, S. 9.]

MULUS, a genus of fishes belonging to the group Aetho-tergei and the family Percidae. The species have the body thick oblong; profile of the head approaching to a vertical line; scales large, deciduous; two dorsal fins widely separated; the pectoral fins well above the pelvic fins; the gill-covers raised and flexible; teeth on the lower jaw and palate only; two cirri at the symphysis of the lower jaw; branchiostegius 14-14. There are two species of this genus found in Europe, and both are inhabitants of the seas of Great Britain. M. Aethopis, the Striped Mullet (M. leuca, Steind) has the following fin-ray formula:—D: 7–1+6; P: 17; V. 5–1+6; A: 2-5+6; C: 13. The forehead, nape, cheeks, and operculum are corred.
Mr. Yarrell states that the Spotted Gannel of America is identical with the British fish.

**MUREX**

**MUREXIDE** [Chamartín, S. 1.]

**MUSCALES**

**MUSCALES** [Chamartín, S. 1.]

**Acrogeous Plants in Lindley's arrangement of the Vegetable Kingdom. It includes two divisions:—1. *Hepatica*; 2. *Musci.* The *Hepatica* include the orders Rícicaceae, Marchantiaceae, Jungermanniaceae, and Lacióideae. The *Musci* include the orders Androcides and Bryaceae.

**MUSCARDINE**, the name given to a disease to which silk-worms are subject, and which often causes great injury to those who cultivate these animals for the sake of their silks. This disease is caused by a fungus belonging to the genus *Botrytis,* and has been named by Balsamo and Montague B. *Basiana.* This plant, which is characteristic of the disease, can be propagated by the inoculation of a healthy caterpillar. The result of the changes produced upon the blood and tissues of the animal is its death. This disease is much more common some years than others. It frequently spreads to other insects; and the caterpillars of other *Lepidóptera* can be inoculated by the spores of the fungus. When once the disease has appeared there seems to be no means of checking it. The best mode of prevention is to take care that the caterpillars are not overcrowded, and that they have a sufficient supply of fresh food. The predisposition to this disease is among some species of butterflies, and causes as those which act upon the human system, and render it favourable to the attacks of epidemic diseases.

(Robin, *Histoire des Végeaux Parasites*)

**MUSCA* orbicularis,* a common black ant of the coast of Arabia, is found in the province of Oman, is situated on a peninsula which is joined to the island of Muscat by a reef of rocks, in 23° 48' N., 58° 40' E. long., and has about 60,000 inhabitants. High lands to the south and west, and the island towards the east shelter the harbour, the entrance to which is from the northward, and protected by forts on each side; within there is room enough for a large fleet to moor in 4 or 5 fathoms water. A fort close to the town, and two other forts on the headland dominate the whole of the port. The town is surrounded by walls and turrets built with stone houses, and is accordingly fortified. The houses are only one story high, with the exception of some handsome stone buildings erected by the Portuguese. There are also some houses built in the Persian style, and an aqueduct.

Muscat is a great commercial entrepot, and has a very active trade. A large number of ships belong to it, and trade to British India, Sumatra, the Malay Peninsula, the Red Sea, and eastern coast of Africa, the Comoro Isles, and Madagascar. In the trade between Arabia, India, and Africa and China, they may be set down as belonging to Muscat. The port is resorted to by ships from every port of Persia and Arabia. British and French merchants trading to the Peninsula of Muscat are very numerous. Besides its maritime commerce, Muscat carries on an extensive trade with the Arab tribes of the interior. The principal articles of the commerce of Muscat are—saffron, almonds, raisins, pistachio nuts, souchote aloes, gum ammoniac, sulphur, gum copal, and saltpetre. Other articles are frankincense, pears, gall-nuts, coffee, cocoa-nut-oil, galbanum, hides, cotton-wool, mother-of-pearl, gum, bees-wax, raw silk, indigo, tortoise-shell, rhinoceros-horns, pepper, cochineal, cinnamon, sugar, rice, sandal-wood, dates, saffron, wheat, horses, salt, dried fish, &c. Most of these articles are imported in Arab vessels from Persia, Zanzibar, Africa, and Western Arabia, and are exported to India, the Mauritius, Bourbon, Calcutta, Bombay, America, France, Zanzibar, &c. The tissus imported at Muscat are British and American long-cloths, British calico-prints, India shawls, Chinese silks, &c. The country near the town is barren; but pro visions, fruits, vegetables, and fresh fish are abundant in the markets. Bullocks, sheep, and annals are to be had at a reasonable price. The usual imports into Muscat are probably under-estimated at a million sterling. Imports pay a duty of 5 per cent. if coming from Arabia, America, or Great Britain; 4 per cent. if coming from Bourbon. No duties are payable on fish. There is a large town called *Muttra,* 3 miles to the westward, nearly as large as Muscat. There is a good road between the two places. At Muttra vessels can be hailed ashore. In the interior there is another large town called *Rostam.*

Muscat was a place of considerable trade before the arrival of the Portuguese in the Indian Ocean, and it was then
subject to Oman. Alberquerque took it in 1507, but had immediately to put down a bloody insurrection of the Arabs. On the same year the Portugeuses, with the primary centre of trade in this part of the East, and yielded enormous profits to the Portuguese, who held the town till 1648. During this interval they built the fortifications and greatly improved the town. The town of Mascate is the principal seat of the Arabs. It is situated near the top of the Muscat peninsula, and is approached by a narrow isthmus, about one mile in width, which is crossed by a wooden bridge. The town is built on the hilltop, and has a picturesque appearance.

Left to themselves, the Arabs of Muscat—expert seamen, skilled in the use of fire-arms—soon raised a maritime force which became the terror of all the neighboring coasts, but also the European powers, all of which desired to hold them in check. The Portugeuses themselves mastered several places in the Persian Gulf, and were threatening Gomhoura; and the British government, acting upon the report of their resident at that place, proposed to send out an armament to clear the Indian seas, and "to root out that nest of pirates the Muscate Arabs." In 1707 the Portugeuses obtained permission to build ships at the ports of Pegu from the king of that country; and their fleets, consisting of ships of 20 to 50 guns, annoyed trade in the Persian Gulf. The British, however, had now a footing on the lower coast of the Red Sea, and were more important in holding the line along the Malabar coast. With the Persians they were almost continually at war; although Persian traders were always permitted to trade at Muscat or any of its dependencies on the east coast of Arabia. In the Middle of the 19th century the British had no connexions with the Muscat government; and the British and European powers were thus in a better position to control the sea trade of the Persian Gulf than they had been at any previous time.

The Imam of Muscat claims as his possessions in Asia all the south-east coast of Arabia from the frontier of the British settlement of Aden to Ras-el-Had; all the territory of Oman along the east coast of Arabia, the sea-coast and islands in the Persian Gulf, including the Bahrein Islands and the pearl-fishery contiguous to them; and the coast of the Makran. In Africa he claims sovereignty over all the coast from Cape Delgado to Cape Gardafui, including the ports of Montgomo, Lindi, Quila, Melinda, Lamoo, Brava, Magdoua, &c.; and the valuable islands of Malac, Comor, Remba, Socota, &c. Only a small part of this immense territory is garrisoned by his troops; but all, or nearly all, of it is tributary to him. He rules with patriarchal and despotic sway, and in his vast and illimitable dominion he is absolute and uncontrolled. A foreigner may walk the streets of Muscat at any hour of the night unmolested. Goods are piled up in the streets exposed night and day, and no one ever attempts to molest them.

The Imam derives his revenue, which is more than adequate to his expenditure, chiefly from commerce, in which he employs a great number of merchant vessels; from import duties on foreign merchandise; and from tribute money or the equivalent present received by him by princes under his sway. His naval force, more efficient than that of all the native emperors and princes from the Cape of Good Hope to Japan, numbered in 1837 15 vessels, carrying from 6 to 74 guns; 60 baghehas (one-masted vessels of 200 to 300 tons), carrying 10 to 15 guns; 10 balloons (100 to 200 tops), carrying 4 to 6 guns. The number of vessels belonging to the port of Muscat at the same time, was estimated at 2000 of all sizes, a very large proportion of these being small craft. He has intelligent officers and abundance of sailors; but he keeps only a small number of regular troops, as he can have any number of Bedouins whenever he wants them, merely for the clothing and maintenance. His naval force however is sufficient to enable him to maintain his power, and to resist all pretensions over all the territories he claims as his own.
ridicule which has been thrown upon this opinion in a recent
entomological work, it appears, from still more recent inves-
tigations, that the theory is far from being hitherto advanced.
Thus, in general, the foot of the fly is described as being
composed of two hooks and two flaps, or hollow cups, which
act as suckers. Bymer Jones, in his "General Outlines of
the Animal Kingdom," 1864, says: — "The House-Fly is fur-
nurished with a minute series of suckers or tubules, visible un-
der the microscope, are seen to be covered with innumerable hairs
of the utmost delicacy; these flaps, or suckers, as they might
be termed, adhere, &c."

The description of the foot of the fly has recently been ex-
anamated by Mr. Hepworth, who says: — "The fly varies in
form in different species, from an irregular circle to that of
an irregular triangle; and viewing it from one side, it is
somewhat thicker at the base (near its attachment), the
underside of the segments forming an arched convexity, but perfectly flat
as a whole, when applied to the surface of that form.
It appeared to be composed of an upper and under layer of
areolar tissue, or something similar to it, between which a
bundle of tubes, along with the fasciculi of a large muscle
pair; these are placed at its base, and (sometimes protected by a
'coat of mail,' formed by long scales overlapping each other
as a Venetian blind, or in alternate ones, as the scales of
a fish, &c., but more frequently wanting) expand in a radi-
ating manner from the base so that the ends pass along with its fellow
on each side, gives off a number of tubules alternately with
them; these dip downwards from the under surface, and
become expanded into trumpet-shaped extremities, the flap,
becoming thinner and thinner as it approaches its margin,
while sometimes terminates in an irregular serrated apex,
and at others by finely pointed hairs. The fly has the
power of attaching itself to smooth surfaces by these trumpet-
shaped extremities, and also of secreting a fluid from them,
when vigorous, and it has occasion to make extra exertions
but in a partially dormant state (the best for making observa-
tions), it does not appear to be able to give out this secretion,
even though it cannot attach itself; indeed this fluid is not
essential for that purpose: when it is secreted, it is deposited on
the flap with the concavity of the segments, and generally,
and from the necessity of secreting the maximum fluid to
preserve these markings by applying colouring matter
whilst they were moist, but have not yet succeeded.
The tubules are often seen protruding from under the margin of
the flap in a semi-arch-like form, giving it a fringed appear-
ance. The foot of the male Dytiscus is a type, not only
of many of the beetle tribe (not aquatic), but of the whole of
that of flies possessed of flaps. The first joints of the tarsi of
the anterior legs of this insect are extremely dilated so
that a band of membranous flap forms on each side of the
inferior surface of this expanded portion, it is seen to be
covered with a great number of sucking cups, two or three
being larger than the rest, but they form collectively a very
powerful instrument of adhesion." (Quarterly Journal of
Mus. Mus., S. 1.)

MUSCLES. [MUSCULAR TISSUE. [Tissues, Organic, S. 1.]

MUSK-BOAT. [Ceratodidae.]

MUSK-ORCHIS. [Hérmium, S. 2.]

MUSK-ÖX. (Ox.)

MUSK-ROOT. (the root of a plant brought to this country
from Russia and Persia, and known also by the name of
Sumbul. This root exhaled a powerful smell of musk, and
has been used in medicine as a substitute for that substance.
The plant yielding it is not known, but the root has the
appearance of belonging to the natural order Umbelliferae.
Its tissues are full of starch.

MYCETCHARUS. [Corticiidae.]

MYGINDA. [Ampullaceae.]

MYPHONUS. [Coniidae.]

MYOPTERIS. [Chloropteris.]

MYOSURUS (from μύος, a mouse, and σύρε, to pull, the
seed being sown on a long receptacle which looks exactly
like a tail, a genus of Plants belonging to the natural order Ranunulacae. It
carry a calyx of 5 sepals, prolonged into a spine at the base; the petals 5, with a fil-
atum tubular claw; the capsules closely imbricated upon a long axis, regisses for 2 to 3 years, if the embryo
inverted with the radicle superior. The only
species of this genus is M. minus, which has a simple
leafless single-flowered stem 2 to 6 inches high. It
has a very long receptacle, numerous carpels, and many large
It grows in damp places and in fields. It is a native of
Europe and America. The American plant has been de-
scribed as M. Shorti, but there is every reason to believe it
is the same as the British and other European plants.

MYRIAPODA, a class of Invertebrates Animals belong-
ing to the class Articulata. This order is represented by such species as the
Centipede and Gallow-Worm. They may be regarded as an intermediate form between the lower
and higher forms of animals. They are provided with
the Annulose forms in the longitudinal extension of their
trunk, in the similarity of the segments from one end of
the body to the other, and in their cylindrical form. On the
other hand, they possess the most peculiar eyes than any of the
Vermiform tribes, and their respiratory organs. The parts
of their organisation are more nearly allied to Insects.
Their covering is firm, and of a horny character.
The division into segments is very distinct, a flexible
membrane being interposed between each pair of
plates. The legs and other appendages are inclosed
in the same kind of integument, and their joints are formed in
the same manner as those of the body. We find in this class
however two distinct types of conformation, of which one
approximates most nearly to the Vermiform tribes, and the other
to that of the higher Articulata; in the former of which the
Tulis (Gally-Worm) may be taken as an example.
The body is generally cylindrical, or nearly so; the number
of the segments is variable; they have a pair of thread-like legs, so
that the number of these members sometimes amounts to
160 pairs. The legs are very imperfectly developed, being scarcely large or strong enough
to sustain the weight of the body, and their articulations being
so distinct, that they are unable to support it. The animal,
with their assistance, like a serpent or a worm, than to use them
as their proper instruments of locomotion. This kind
of movement is facilitated in some species by the incomplete
inclusion of the body in the consolidated integument, for
this merely forms plates above and below, the number
of segments is not very great, never exceeding 22, and being
sometimes as low as 12; and each segment bears a pair of
well-developed legs, on which these animals can run with
considerable speed. Still the animal, instead of relying
on such legs for propulsion, possesses a considerable
flexibility; and they are thus enabled to wind their
way with facility through very narrow and tortuous
tubes, without injury. The animal, after having--

The alimentary canal is mostly divided into gullet, stomach,
and intestine. The stomach usually presents distinct
muscular walls. The circulatory organs consist of a dorsal
vessel, which propels a current of blood from behind for-
wards, which is distributed to the body and respiratory
organs. In the higher forms respiration is effected by mea-
s of tracheae, which convey air into the interior of the body
as in Insects. The nervous system is arranged in a double
series of ganglia, as in most of the Articulated Tribes. They
possess cephalic ganglia, which meet above the esophagus,
and form a two-lobed mass, from which nerves proceed to
the eyes and antennae. In many parts of the double series
of cords the ganglia of each side unite. The muscular
apparatus is very complicated, consisting of a series of distinct
muscles for different purposes. They have a pair of
ovaries and testicles, and the sexes are separate. The embryo
at the period of hatching consists of but few segments, but these increase in number
till it is fully grown by the subdivision of the penultimate
segment. In the formation of the larva the head remains
and they go on increasing in number till there are sixty or
seventy. The larva has no legs, these organs making their
3 L 2
appearance after the first moult. During their growth these animals have a considerable power of regenerating lost portions of their body as the legs and antennae, but this power is lost when they cease to develop.

Mr. Newport divides the Myriapoda into two orders—\textit{Chilopoda} and \textit{Chilognatha}. \cite{Curtis, Curtius.} The following synopsis of the genera of these two orders is drawn up from the list of the specimens of \textit{Myriapoda} in the collection of the British Museum (1844):—

\textbf{Order I. Chilopoda.}

\textbf{Order II. Chilognatha.}

protruding their bodies. Some have black points on their heads, which have been regarded as eyes. To this family belong a large number of little-studied forms of very minute fresh-water worms. The smaller ones are sometimes called Vinegar-worms, and their commonest food is the ammoniacal exudate of the amateur microscopist is an example. It also appears to embrace the Syllogra of Lamark, the Proto of Oken, and the Clypeus of Swann.

The compounds of Carbon and Hydrogen, frequently found in the neighbourhood of coal-deposits, and in other parts of the earth. It contains 82.2 of carbon and 14.8 of Hydrogen. It is a limpid or yellowish fluid, lighter than water, and hence called Mineral Oil. Its specific gravity is from 0.83 to 0.86. It is sometimes called a substance called Petroleum on exposure to air. It may be obtained from Petroleum by heat, which causes it to pass off in vapour.

Vapours issues in large quantities from the earth in Persia and the Birman Empire. At Ranang, on one of the branches of the river Irawaddi, there are upwards of 500,000 naphtha and petroleum wells, which afford annually 419,000 hogsheads. In the peninsula of Belcheri, on the western shore of the Caspian, naphtha rises through a marshy soil in vapour, and is collected by sinking pits several yards in depth, into which the naphtha flows. There is a abundant spring near Amiana, in the Duchy of Pras. Mr. Dana says that in the United States it was formerly collected for sale by the Seminoles, and that the late General Marion used it commonly called Genesee or Seneca Oil, under which name it is sold in the market.

Petroleum is used as lamp-oil in Birma, and when mixed with water, is called a “Kerosene” lamp. It is used for fuel and light by the inhabitants of Bagou, on the Caspian. The vapour is made to pass through earthen tubes, and is inflamed as it passes out, and used in cooking. The spring at Amiana is used for illuminating the city of Genoa.

Naphtha has been recommended as a medicine, and is found to be a good stimulant in some chronic diseases. It has been externally applied as a lotion in cutaneous affections. It is sometimes substituted for drying oil in making paint. It is also employed for preserving the metals of the alkalies potassiam and sodium, which cannot be kept in contact with any substance containing oxygen.

The Ranang petroleum contains the compound Paraffine. This substance has also been obtained pure in a liquid form from the coal-pits of Derbyshire. It is used for the purpose of diminishing the friction of machinery as a substitute for sperm-oil. It is now obtained artificially from coal, and in a solid form, from which candles are made.

(From: Manual of Mineralogy; Gregory, Handbook of Organic Chemistry.)

**NAPHTHALINE. [CHEMISTRY, S.2.]**

NAPIER, SIR CHARLES JAMES, G.C.B., was the eldest son of Colonel the Hon. G. Napier, comptroller of ascension and other charters, and nephew of Charles, second duke of Richmond. He was born at Whitehall, on the 10th of August, 1782. Having received his early education under his father in Ireland, he obtained his first commission as ensign in the 22nd foot before he had completed his twelfth year, and first saw active service during the Irish rebellion of 1798, and again in the insurrection of 1803. In 1806, having obtained his company, he joined the British forces in Spain, and commanded the 50th regiment of foot during the extraordinary campaign under Sir John Moore, on which occasion he received five wounds, and was taken prisoner. Being allowed to go to England on parole, he found his friends actually in mourning for him as dead, and administering his effects; and he employed his period of compulsory inactivity by writing on colonies, colonisation, and military law, and an essay on the state of Ireland. In 1809 he again joined the British army in the Peninsula as a volunteer. He had two horses shot under him in the desperate conflicts on the banks of the river Coa, and was carried into the hard-fought battle of Fuentes de Oñoro, and in the second siege of Badajoz, as well as in a considerable number of lesser skirmishes. In 1813 we find him serving in the Netherlands, and having no longer need of his services, and occupying his time by the capture of American vessels, and frequent descents upon the coast. He returned to Europe a few days too late to be present at the battle of Waterloo, though he took part in the storming of Cambrai, and accompanied the British army to Paris.

Not long after this, while stationed in the Ionian Islands, he was appointed governor of Cephalonia. Here his administrative powers were first developed; and the success of his governorship is proved by the fact that to the day of his death he retained the title of Lord Viscount of Cephalonia. In 1831 he returned to England, and received an annual tribute of the produce of their vines. While holding this post he joined with Lord Byron in a scheme for the deliverance of Greece. He was shortly afterwards superseded on the latter ground, but continued to pursue his agricultural in a most successful manner. In 1838 and 1839, Sir Charles Napier, now a major-general, was ordered in 1841 to take command of the 3rd division of the army. This was the beginning of his military career. At Bombay he attracted attention by his energetic plans of military reform, to which he continued to devote himself until the appointment of Lord Ellenborough to the governor-generalship of India. At his suggestion Sir Charles Napier drew out the plan of an Afghan Campaign. Since at this time was in a very disordered condition, and the British influence and prestige had been much impaired by the disasters in Cabul. The Ameers of Sind were perfidious, and as they would be bound by no treaty, he resolved to subdue them by open attack. From the first, his plans were eminently successful. He blew up the fortress of Emam Ghur, which was always deemed impregnable. Having accomplished this exploit, which was characterized by a large amount of bravery, he proceeded on with the capture of the whole province and extraordinary of all military feats, he pressed on, and with a very inferior force in point of numbers routed the Ameers at Meenanee, February 17, 1843. In a few days the army took Buner, and after passing the province of Hyderabad, and outflanking Shere Mohammed (surnamed the Lion) on the other side, drove him from the field with prodigious slaughter. Having now become master of the fair territory of Sind, Sir Charles Napier set vigorously to work to improve its condition. He organised the provincial government, and the collection of taxes, amended the native law, put down the ‘sutter’s system’, and set the tenures of land on a more just and judicious footing. Whilst in the midst of carrying out these reforms Lord Ellenborough was recalled by the East India Company, and Sir Charles Napier felt that he had lost his best friend and supporter. His Indian services are thus summed up, in the words of his brother Sir William Napier, in his ‘Narrative of the Administration of Scinde’—"Two years only elapsed since he quitted Lucknow to make war on the Ameers, and in that time he had made the march to Emaum Ghur in the great desert, gained two great battles, reduced four large and many smaller fortresses, captured six sovereign princes, and subdued a great kingdom. He created and put into the administration of Scinde, and under its branches, conciliated the affection of the different races which inhabited Scinde, had seized all the points of an intricate foreign policy, commenced a number of military establishments in the public service, and had prepared and for greater ones, not only suited to the exigencies of the moment, but having also a prospective utility of aim." And all these works he performed in spite of a press of correspondence, long journeys on camels and horseback beneath a tropical sun, and under frequent and severe attacks of illness, at the age of sixty-three, and in spite of every mortification that malice and intrigue could devise against him. Unwilling to leave Scinde without some permanent proof of his ascendancy over the popu Indian, and of the consciousness of having contributed to the temporary prosperity, he persuaded the people to change the feudal system of land-tenure for that of landlord and tenant, considering that such was the best plan of forming loyal subjects by raising a class of farmers and small landholders attached to the government, by ties of a personal and pecuniary interest.

In 1847 Sir Charles Napier returned home, and met with an enthusiastic reception; but ever ready at the call of duty, he reembarked for India in March 1846, at the suggestion of Government. On the 25th of December he went to theMahamadnagar, where he received the reverse of which we had sustained in the Sikh campaign. Happily however on his arrival at Bombay he found that the tide had turned, and that his military services were no longer so urgent as they had been, and that he had more leisure to enjoy the pleasures of his field, and no principality to administer; so he set his active mind to work forthwith to carry out a system of military reform, his immediate object being to school the luxury and extravagance of the British officers into a simple and severe mode of living. In this work he was partially successful.
He returned to England in 1850, but his health and spirits were fast failing, and the last time that he appeared in public was on the occasion of the funeral of his friend and patron, the Duke of Wellington, in November 1852. He died of a gradual decline at Oaklands, his seat, near Portsmouth, on the 29th of August, 1853, like a gallant soldier, under the old colours of the 22nd regiment and other trophies of his European and Indian campaigns, and was buried in the grounds attached to the mansion chapel at Landport, near Portsmouth. Sir Charles Napier was twice married—first in 1827, to Elizabeth, daughter of John Oakley, Esq., of Deal, Kent, by whom he had two daughters; and secondly, in 1835, to Frances, daughter of William Phillips, Esq., and widow of Captain R. Alcock, R. N. A bronze statue of the conqueror of Sinde has been erected by subscription in Trafalgar-square.

NAPLES.—The territorial divisions of the kingdom of the Two Sicilies are divided into 15 provinces, the areas, subdivisions, and population of which are given in the subjoined table. The provinces beyond the Faro are given under Sicily, &c. 2.

Population of Sicily at the Census of 1861: 2,091,880
Total population of the kingdom of the Two Sicilies: 6,704,472

NARBERTH. [Pembroke.] NARCISUS, a genus of Plants belonging to the class Ephedres and the natural order Amaranthaceae, among which it is known by its flowers growing upon a scape, and having a cup at their mouth; the stamens, which are opposite the sepals being longer than the others. It consists of bulbous plants principally inhabiting the warmer parts of Europe. The following is the arrangement of the European species of this genus given in Mr. Wood's 'Tourist's Floras':

- A. Leaves flat, linear, obtuse; tube of corolla short, obversely conical; crown campanulate dentate.
- N. Pseudonarcissus, the Daffodil. Scape 2-edged striate; flowers nearly sessile in sheath; crown erect, nearly as long as segments of corolla; stamens equal. It is found in woods and meadows throughout Europe.
- N. Minor, a native of Europe.
- N. Incomparabilis has the scape 2-edged. It is found in France and Italy and the coasts of the Mediterranean, and is naturalised in Great Britain.

B. Leaves nearly flat; flowers hypocrateriform.

I. Scape nearly terete.

II. Scape 2-edged.
- N. poeticus. Scape 1-flowered; petals white. It is found on open heathy fields in Norfolk and Kent, in Great Britain; it is also found in Austria and various parts of Italy.
- N. radiatus. Scape 1-flowered; striate. It is found in Austria, Styria, and the Valtellina.
- N. Silenus, with linear-obtuse keeled leaves; scape compressed, 2-edged, striated, 3-flowered, crowned, very short, concave, crenate at the pale margin; the petals of a pale sulphur colour. It is found in sandy fields in the south of England, and in Ireland, also in France and Italy.
- N. palaetus, N. procax, and N. Tazetta, are other European species belonging to this section.

b. Crown and petals white.
- N. polyanthus. Scape slightly 2-edged, 8-20-flowered. It is found near Toulon and Nice, in stony places.
- N. nivens. Scape 6-10-flowered. It is a native of France.
- N. unicolor. Scape 10-15-flowered. It is found at the base of Vesuvius.
- C. Leaves convolute-setaceous.
- N. tenuissima. Scape 1-flowered. It is found near Palermo, on open hills.
- N. cynapiifolium has the scape 3-flowered, and is found on the coasts of Corsica, Sardinia, Calabria, and Sicily.

D. Leaves semi-cylindrical and crenellated.
- N. Lautis has the scape 1-2-flowered. Found near Grasse, in France.
- N. ochroleucus. Scape 4-8-flowered. Found in fields near Toulon.
- N. odoratus. Scape 1-5-flowered. It is found in the fields and olive grounds of Lucca.
- N. jonquilla, the Jonquil. Scape 2-6-flowered. It is found in Italy. N. intermedia is probably a variety of this species.

The species, from their hardiness or gay colours, or sweet smell, have long been favourite objects of cultivation, especially the Daffodils, Jonquils, and Tazettas. A very full account of them is found in the 'Amaranthaceae of the Honourable and Reverend William Herbert, p. 329 (Svo., London, 1837), who however divides the genus into six sorts, after the example of Salisburry and Haworth; but as these genera are not likely to be adopted by botanists, with the exception perhaps of the genus Cortusella, no account need be given of them. With regard to Corbridaria, to which the name of Hoop-Petticoat Narcissus is given, and of which five supposed species are enumerated, the peculiar form of the flower and the delicate stamens of that plant may perhaps entitle it to be regarded as a peculiar genus; the species are pretty, all yellow-flowered, with the single exception of C. cantabrica, a little plant with white flowers found on the mountains of Bisaye and the Pyrenees, but now lost in the French list.

NATALS, a British colony on the south-east coast of Africa, is bounded S.W. by the river Utuaco (about 30 miles W. from the Umsimudula, the previous boundary), N.E. by the river Tugia, N. by the Drenchenberg or Quatlabma Mountains and the S.E. by the Indian Ocean. The colony lies between 20° 20' and 30° 50' S. lat., 30° 40' and 31° 25' E. long. The area is about 29,000 square miles. The white population in 1853 was 7039, the native population 112,936.

The Drenchenberg or Quatlabma Mountains form a broad range which runs nearly parallel with the coast, at a distance varying from 60 to 90 miles from the shore. The average height of the range may be estimated at 8000 or 8000 feet above the sea, and the summits are covered with snow at least four months in the year. On the north-west, or interior side, a table-land slopes gradually down almost from the summits of the mountains, exhibiting extensive plains, diversified by a few isolated mountain-groups and low ranges of hills. There is no pass in the whole range between 25° 50' and 31° S. lat. practicable for horses or coachages, and there are very few for pedestrians. Coal occurs not far from the sources of the Tugia, and ironstone is frequently found. Copper has been discovered within 20 miles of Pietermaritzburg. In Natal the country gradually rises from the sea to the foot of the mountains. A few mountainous groups occur which are offsets from the Drenchenberg range. The country is diversified with hill and dale.

The rivers are very numerous, and all flow eastward to the sea. Two of the largest are the Tugia and the Umzimudula; they both rise in the Drenchenberg Mountains. The Tugia receives several tributaries, of which the principal is the Drakenstein, which forms a portion of the boundary to the north, and the Bushman River; and it reaches the sea in 29° 16' S. lat., 31° 22' E. long. It has a bar at the
mouth, and is not navigable. The Umrincula flows through a rugged and almost inaccessible country, and falls into the sea in 30° 50' S. lat., 29° 20' E. long.

Along the coast, in summer, the average temperature is about 74° Fahr.; in winter about 63°. Nearer the mountains the climate becomes colder. The rains generally commence in March, and end in September. Thunder-storms are of frequent occurrence, and are very violent. The climate, on the whole, is healthy. The soil is generally very fertile throughout the Cape Colony, and does not appear to suffer so much from droughts.

The elephant, which was formerly common in the colony, is now nearly driven away. The lion and leopard are still met with along the mountain ranges. Hyenas, jackals, wild dogs, ant-eaters, and porcupines are numerous. The hippopotamus abounds in several of the rivers, and in the Tugela there are numbers of small crocodiles. The larger antelopes are becoming scarce; but there are still many of the smaller ones. The giraffe, a beautiful and graceful animal, is abundant.

Several valuable timber-trees grow on the declivities of the mountains and in the mountain valleys.

The colony of Natal is divided into the districts of Pietermaritzburg, Durban, Bophutatswana, and to a tract in the south-west part of the territory. The principal town in the colony is Pietermaritzburg, founded by the Dutch boers in 1840, and containing about 3000 inhabitants. It is situated on an offshoot of the Drakensberg Mountains, in 29° 30' S. lat., 3° 0' E. long., about 50 miles W.N.W. from Port Natal. It contains a barracks, ordnance stores, and Dutch, Episcopal, and Methodist places of worship. It is well supplied with water. D'Urban, the only port of the colony, is situated on the east side of the inlet called Port Natal, which is a bay completely landlocked, and affording good anchorage. The entrance is narrow, and is impeded by a bar, on which there is sometimes not more than two fathoms of water. The Cape at the entrance of Port Natal is in 29° 53' S. lat., 31° 3' E. long. Verulam, Windsor, and Western are the largest of the villages.

The white population of the colony is mostly composed of the original Dutch settlers who remained after the dispersion of the boers in 1842, and of the immigrants who have since arrived. The total number of the inhabitants in 1845 amounted to 25,464 15s.; the export duties of the colony amounted to 54,285 15s.; the value of the exports in 1845 amounted to £124,723 2s. 9d.; the value of the produce exported being £9,905,838 15s., of which the wool exported was valued at £1,474,116. A bishopric of Natal was created in 1853. There are episcopal ministers at Pietermaritzburg and D'Urban.

The colony of Natal owes its origin to the Dutch boers (farmers), who in the year 1836 emigrated northward beyond the Orange River, and crossed the Vaal, the Tugela, and the Drakenburg Mountains, settling in small communities in different parts of the unoccupied territory. These emigrants in 1838 employed their commandant, Pieter Retief, to enter into a treaty with Dingaan, the chief of the Zooloos, Retief continued the autocratic policy of his predecessors, and arrived at the treaty by massacre. The Zooloos were reduced to 70 or 80 farmers, and their families and attendants, who visited Dingaan at his place of residence, preparatory to forming their intended establishment in the vicinity of Port Natal. They were received by the Zooloo chief and his warriors with every demonstration of kindness, but were treacherously surrounded and slain in the midst of perfectly friendly festivities. The farmers scattered over the territory of the Zooloos, next attacked successively, and upward of 600 men, women, and children were killed, besides those who had been previously massacred at Dingaan's residence. The great body of emigrants, who still remained behind the Drakensberg Mountains, sent off expedition after expedition against Dingaan, in February 1838, succeeded in putting him to flight. The Queen of the Dutch farmers then removed to Port Natal, where, in December 1839, they hoisted the tricolor flag, and proclaimed an independent republic, with Andreas Wilhelm Pretorius for president. The British government refused to acknowledge their independence, and Sir George Napier, then governor of the Cape Colony, sent some troops to take possession of Port Natal. They entrenched themselves, and maintained their position till the arrival of reinforcements by sea, in June 1842, when the Dutch were compelled to submit. A proclamation dated August 21, 1845, the colony of Natal was established by the British government.

NATURALIZATION. A simple and inexpensive method of obtaining naturalization has been provided by the statute 7 & 8 Vict. c. 68, which enables the Home Secretary to sign a certificate entitled an alien, on his taking an oath of allegiance and fidelity, to all the capacities and rights of a British subject, except those of sitting in Parliament, or being a member of any Company of Weds; and the rights, when granted, are considered to confer the alien a temporary character only as a subject; that is, the alien cannot, on returning to his own country, claim the protection of British law as a natural-born subject. The same statute declares the right of every person who is an citizen to hold every species of personal property, except chattels real; and every resident alien any to hold lands or houses for residence, trade, business, or manufacture, for a term not exceeding twenty years; but this exception not, however, conferring any right to vote for a representative in Parliament.

The statute enables all persons born abroad of a mother who is a natural-born subject, to take any real or personal estate by descent, purchase, or succession; and it naturalizes de facto any alien woman who marries a British subject; in consequence of which, the notorious Mrs. Manning when indicted with her husband for murder, was held not entitled to a jury de modicate lingue.

NAUVOO. [Utah.]

NAVARRETE, MARTIN FERNANDEZ DE, a Spanish scientific naval officer and historical investigator, who had the good fortune to bring to light materials of inestimable value at the decline of the old and in the age of the modern era. His life is a history of travels and of discoveries, of expeditions and of misfortunes. He joined the Spanish fleet under Cordova, which, during that part of the American war, cruised unassailed in the English Channel; and he was at the disastrous attack on the Spanish floating batteries on Gibraltar, in September 1782. After some cruises against the Moors and Algerines, Navarrete was, in 1789, obliged to quit active service for some time on account of the state of his health, and his character of a soldier became that of a peaceful scholar. He was appointed a member of the commission from the new king, Charles IV., to examine the national archives to form a collection of documents relative to the naval history of the kingdom, and in particular that of the voyages of discovery which have conferred such immortal fame on the nation. Navarrete's great work, the first volume of which did not appear till thirty-six years after. In 1793 the Spanish declaration of war against the French republic recalled him to sea, and in 1794 the declaration of war with England kept
him there; but his health was still weak, and when in 1797 his friend Langara became minister of marine he provided Navarrete (now risen to the rank of captain in the navy) with a post in his office at Madrid. His life after this appears to have been as undisturbed by violent changes as a life in the navy could possibly be. At the close of the war of independence he refused to accept office under the French, and he removed to Seville, but he took no active share in the war. He was re-instated in office as soon as Ferdinand returned, and for many years continued to be the Admiral of the Black Sea, but left behind him a vast store of Hydrographic works, although the title he bore was that of chief of the Hydrographic department, to which he was appointed in 1823. In the midst of his official duties his seal for literature, he wrote a volume of poems, though he never showed them to any but his most intimate friends. As a member of the Spanish Academy, he proposed, about 1815, the new system of orthography which was adopted for its Dictionary, and has been followed by many of the Spanish writers. As secretary of the Academy of San Fernando, which is that of the Fine Arts, he was always at his post, and to their 'Transactions,' and those of the Academy of History, he was a contributor of valuable papers. He was also the author of numerous works, some of which are of great importance from the information they contain. He held his offices and also a distinguished place in the literary society of Madrid through several revolutions; and in 1834, when the Estatuto Real was published, on the morning of November 29, he was one of the first peers created. He died at Madrid, on the 8th of October 1844, at the age of seventy-eight.

The great work of Navarrete is the 'Coleccion de los Viajes, descubrimientos y exploraciones de los españoles desde fines del siglo XV.' ('Collection of the voyages, explorations, and maritime discoveries made by the Spaniards since the close of the 15th century.') The work was to consist of seven quarto volumes: the first and second were published in 1833, the third in 1839, the fourth and fifth in 1842, the sixth and seventh, chiefly consisting of documents relating to Columbus, have not yet appeared in print, but the materials for them were left by Navarrete at his death, arranged for publication and only awaiting the introductions and notes he intended to add to them. The book is described by Humboldt as "one of the most important historical monuments of modern times." Washington Irving, who went to Madrid expressly for the purpose of translating it, afterwards changed his intention, and wrote the new matter which it supplied into the 'Life of Columbus,' in which in fact little belongs to Irving, except the style. This mode of dealing with the materials was perhaps the best that could have been adopted under the circumstances. A French translation of Navarrete's 'Memoria' was published in 1831.

Navarrete was a man who let no day go by without searching into something, who habitually read with a pen in his hand, who made notes from his memory for future use, dates, and other small facts of all kinds, and a talent for combining their results; but he lacked the power of condensation; he was not the man to write a European classic; his prejudice as a Spaniard of the old school influenced not only his writings, but in its absolute theory interfered with his dignity as an historian. Perhaps he did himself an injury by the learning with which he loaded his volumes. In his 'Coleccion the number of new documents brought forward in each volume is often said to be almost as much as one hundred, and while the work is one which is absolutely indelible in the annals of Spain, it is not encumbered with large libraries, nor intended to be consulted by every inquirer into the subject of which it treats, it is little read and is mainly known as a mine for others to dig in. One of the most interesting volumes of the Hakluyt Society, Mr. Major's letters of Columbus, is for the most part taken from it; and there are few other documents in the collection of such surpassing interest as these.

Under a work which Navarrete was connected with was the 'Coleccion de Documentos Inéditos para la Historia de España,' or 'Collection of Unpublished Documents for the History of Spain,' commenced by him in 1842 in conjunction with Don Miguel Salvá and Don Pedro Sainz de Baranda. He was the editor, and in 1846, in a letter to the editors on bringing a number to Navarrete once remarked "Well, volume three is done at last;" "Three," the old man replied with vivacity, "I wish there were three hundred, and that I saw them on my shelves. Without such publications we shall never have a history of Spain." He died when it had reached the fifth volume, and the last numbers we have seen belong to the twenty-fifth, and were issued in 1855, by Don Miguel de Salvá and the Marquis de Pidal, the latter a member of the Spanish Cabinet, and also eminent for his services in the collection. A number of new facts which he had unearthed by patient research. A work entitled 'The Life and Writings of Cervantes, by Thomas Roscoe,' which was published by Tegg in 1839 as a portion of Murray's 'Family Library,' appears to be entirely taken from Navarrete, without acknowledgment; at least in several passages that we have compared we have been unable to discover any difference. A history of the part that the Spaniards took in the Crusades, which was contributed by Navarrete to the 'Memorias' of the Spanish Academy of History, and a translation of which was inserted by Michael in his 'Histoire des Croisades,' was a portion of a general history of maritime affairs in Spain which he left behind him complete, and which is likely to be published by the Spanish Academy. A work on the discovery of Mexico and California was issued in 1846 as a Dissertation on the History of the Nautical and Mathematical Sciences in Spain, which Navarrete had, it is said, been at work upon occasionally for fifty years.

Navarrete's last work was a selection of letters which is a view of the discoveries of the Spaniards on the western coasts of North America, prefixed to a narrative of the 'Voyage of the Sulit and Mexican on the Coast of California,' published in 1802. The book was frequently referred to in the disputes between the English and American governments respecting the Oregon territory.

A collection of the smaller works of Navarrete, 'Coleccion de Obras Menores,' was commenced in 1848 by his sons, but has not been carried further, we believe, than two volumes, though it was intended to consist of five or six, containing a selection from his correspondence, and an extended account of his life and times. The two volumes mainly consist of short biographies of Spanish literary men and seamen, which had mostly been scattered in periodicals and transactions of academies.

NAVENBY. [LINGWORTH]

NAVICULA. [DIATOMACEAE. S. 2]

NAVY BAY, a natural harbour lying between the Atlantic coast of American Columbia on the west and the island of Manoula on the east. The island, which is a mile and a quarter long, a mile broad, and covered with luxuriant trees and shrubs, is separated from the mainland at its southern extremity by a channel of about 100 yards wide, but is only 10 feet deep. The projecting reef stretching out from the mainland, the southern extremity of the bay forms a natural breakwater. The harbour thus formed is accessible at all seasons; it is secure in every wind, with a depth of 6 to 7 fathoms in the middle, and 3 to 4 fathoms within 60 feet of the shore, and capable of containing 300 sail. Navy Bay is the Atlantic terminus of the Panama railway, which from hence to Gatun (7 miles) is carried over a swamp supported on piles. A lighthouse has been erected at the western point of the island.

NAMEHILL. [CUMBERLAND]

NEANDER, JOHANN AUGUST WILHELM, Professor of Theology in the University of Berlin, and a member of the Consistory of the province of Brandenburg, was born in the house of his father, J. G. Neander, at Quedlinburg, October 25, 1780. His early youth was spent in Hamburgh, where he was educated at the Gymnasium, and at the Johanneum, a college founded on the site of the old cathedral, in which is placed the large public library. While pursuing his studies here he became, according to his most sincere and zealous friend, assuming the name of Neander ('a new man,' from the Greek) on his baptism. He then, in 1806, repaired to the University of Halle to study theology, and thence removed
to that of Göttingen. After a short stay in Hamburg, in 1811, he transferred himself to the University of Heidelberg, where he made remarkable philosophical attainments under him, in 1812 he was rising the chair of the History of Christianity and of Christian Life, between 1816 and 1839. These however were only the preparatory labours for his valuable work, "Universal History of the Christian Religion and Church," in 5 vols., issued successively between 1832 and 1845. The history, he says, is at once "a speaking proof of the Divine power of Christianity; a school of Christian experience; a voice sounding through centuries for the edification, the instruction, and the warning of all who are willing to hear." The development of the Christian Church has been to the Christian Church a similar history, the notes of his next work, "Geschichte der Pfänzler и Leitung der Kirche durch die Apostel," in 2 vols., published in 1858-33. In these works he has with great ability combated the errors of St. Paul and of the earliest church, which he was ever as active an opponent as Schleiermacher, Hengstenberg, or Tholuck. In 1838 he issued "Das Leben Jesu in seinem geschichtlichen Zusammenhange" ("The Life of Jesus in its Historical Relations"), a work which was written in direct reflection of that of Strauss bearing a similar title, and which has his "General History of the Church," and the "History of the Apostolic Church," have had great influence in England, and been highly valued. His reputation as a lecturer was also great, and his lectures were numerous attended. To the north-western direction, its course being westerly and its length from north to south is 55 miles; its breadth is about 30 miles; its area is 1278 square miles; and its population in 1862 was 601,034. The province is traversed by several rivers of moderately high forestclad valleys, in the west or western direction from the Rhine, below which it turns to the north-west, crosses the territory of Baden till it reaches that of Hesse-Darmstadt; of this it forms the boundary to its entrance into the Rhine at Mainzheim, a course of about 170 miles. The Neckar receives in this province the Neck, the Kocher, the Jaxt, and a great number of small streams. It is navigable for small craft from Cannstadt. There are several lakes and mineral springs in the Neckar district. The lower course of the Neckar has many islands. The land above the river is exceedingly rich and fertile. The chief products are wheat, hemp, wine, silk, and wood. Horned cattle, sheep, and horses of good breed are numerous. Railroads run from Stuttgart to Heilbronn, and from Stuttgart to Ulm and Feucht. The Rhine is navigable from Ulm a line runs east to Augsburg. From the former line a branch is constructed to join the great trunk line along the right bank of the Rhine at the Bruchsal station, between Carlsruhe and Heidelberg. Towns.—Stuttgart, Cannstadt, Eßlingen, Heilbronn, 38 miles N. by railway from Stuttgart, is situated on the right bank of the Neckar, which is here crossed by a wooden bridge. It is surrounded with high walls and a deep ditch, and contains some good buildings, the most interesting of which are the church of St. Kilian, the town-hall, and the house of the Tentschitc Knights, now used as a barracks. Heilbronn has a gymnasium, a public library, and about 10,000 inhabitants, who are actively engaged in, and in the manufacture of silver ware, carpets, tobacco, white lead, chemical products, gunstock, paper, &c. The navigation of the Neckar below this town is much facilitated by the Wilhelm's Canal. Ludwigshafen, N. of Cannstadt, a mile from the left bank of the Neckar, is a well-built town, with 6908 inhabitants, exclusive of the garrison. The town, which, for its size, is one of the prettiest in Germany, is situated on the right bank of the old German and Flemish schools. The other remarkable objects are the military college, the lyceum, and the arsenal. Woolen cloth, linen, calico, jewellry, leather, nails, and canvas are amongst the industrial products. NECROPHORUS, a genus of Coleopterous Insects belonging...
ing to the family Silphidae. The antennæ are terminated by a nearly globular 4-jointed mass; the body is parallelopediped; and the maxillæ have no horn terminal. There are several species of this genus. They have obtained the name of Burying Beetles, from the peculiar instinct which they exhibit of burying the dead bodies of small animals, such as moles, mice, frogs, &c., as a receptacle for their eggs and larvae. Their power of perception are very strong, and it is surprising how soon they discover a dead body fitted for their purpose, round which they may be observed flying, with the elytra elevated, their dorsal surfaces being applied together. They soon creep beneath the body, and commence securing it, with the antennæ from the sides and under the neck, which by degrees descends into the pit which is thus gradually deepened. When it has reached a sufficient depth, the earth is thrown over it, and the insect deposits its eggs upon it, so that the body when hatched, feeds itself in the midst of a feast, disgusting enough, but suited to its taste. The larva is long, of a dirty-white colour, with the upper surface of the anterior segments armed with a scaly plate of a brown colour, and with small elevated points upon the hinder segments. They have also six scaly legs, and the jaws are robust. When they have attained their full size they bury themselves still deeper in the earth, where they construct an oval cell, the inner surface of which they coat with a gummy secretion. These insects, like many other insects, feed upon carrion, a strong given liking. The habits of these insects have been especially studied by M. Gleditsch, and more recently by various persons in France, who have written upon the subject of destroying these pests, and by whom various points in their economy have been elucidated.

There are a considerable number of species of this genus, some of the largest of which (N. grandis, Fabricius) have been observed in North America. There are seven British species, five of which are distinguished by the golden-coloured bands of the elytra. These species vary amongst themselves in the form of the thorax, the structure of the hind legs, the markings on the elytra, and the colour on the sides of the antennæ. One of the most common species in the Silphia Vespillo (Linnaeus), in which the posterior tibie are curved, and the trochanters furnished with a strong spine. The species vary also in length from half an inch to an inch and a third, which is the length of N. germanicus, the largest and rarest of the British species. (Westwood.)

NEUKOMM, THE CHEVALIER SIGISMUND, a celebrated German composer, was born at Salzburg in 1775. Being related to the family of Haydn, he received his early musical education from him. He was the elder brother of the author of 'The Creation.' From him Neukomm acquired that predilection for sacred music which distinguished him throughout his career. At the age of twenty he went to Vienna, where he met Haydn, and the friendship thus begun, lasted without interruption during the whole of the great master's life. Neukomm's close and unbroken intercourse with Haydn, and admiration of his genius, had a sensible effect on the formation of his own style, which is marked, not only with Haydn's grandeur, symmetry, and clearness, but with many of Haydn's characteristic traits of musical phraseology.

After having gained a high reputation in Germany, Russia, and England, Neukomm came to America in 1889; and his reception by the public was such as to induce him to pass much time in this country. His residence in England was an active period of his life. He here that his greatest works, the oratorios of 'Mount Stau' and 'The Hope of the Dead,' which were composed to German words, was afterwards adapted by himself to an English version of the text, and performed for the first time at the Derby Musical Festival of 1831. 'David,' the oratorio, which he composed for London, was performed expressly for the Birmingham Musical Festival, and performed in 1834. During the same period he gave the English public many vocal pieces, both sacred and secular, which obtained general popularity. Among these, his sacred cantatas, 'Miran,' and 'The Prophecy of Babylon,' and 'Abelam,' are, remarkable for their grandeur, expression, and perfect adaptation of the music to the English poetry, for Neukomm was a perfect master of our language.

The Sea was for a long time the most popular song of his, and it is still frequently heard, and always with pleasure. Neukomm's latest work was 'Twenty Psalms selected from the authorised English Version,' for the use of singing-schools, choruses, and choirs in England. It was written for the Association for the Revival of Sacred Music in Scotland, and published by that body at Edinburgh in 1853. It possesses great value. The most beautiful of the Psalms are selected, and the music, in a plain and simple style, has the grand and beauty which characterises Neukomm's sacred works. A collection of Voluntaries for the Organ—an instrument on which Neukomm was one of the greatest performers in Europe—is among the most important productions he has left in England. There is scarcely a branch of his art which he left untouched. His instrumental compositions, symphonies, quartets, sonatas, &c., are very numerous and of much merit; but it is on his great sacred works that his permanent fame will rest.

In the course of his long life Neukomm received many of the honours due to the highest distinction in his art. He was invested with several orders of knighthood, in France, Portugal, and Prussia. He was a member of the Royal Academy of Arts in Prussia, and the principal musical institutions in the more important societies in Europe and the United States. He was a Doctor of Music in the University of Dublin, and he was one of the jury of our great London Exhibition in 1851. For several years he was afflicted with an ailment, at one time almost amounting to deprivation of sight; but he partially recovered from it, and, rested at Bonn, enjoying till he was fourscore, a great old age and an honoured retirement. He died in April, 1856.

NEVIN. [Carnarvonshire.]

NEW GRANADA. [Granada, New.]

NEW GUINEA. [Papua.]

NEW JERSEY. [Jersey, New.]

NEW MEXICO, a Territory of the United States of North America, lying between 31° and 38° N. lat., 107° and 117° W. long. It is bounded S.E. and by the State of Texas from which it is divided on the S. by the parallel of 31° lat., and on the E. by the meridian of 105° W. long.; by the Territory of Utah; W. by the State of California; and S. by the Republic of Mexico. The area of New Mexico is estimated at 210,774 square miles. The white population was 61,826 in 1850. The Indian population was estimated by the Commission of Indian Affairs in 1853 at 45,000. The Territory of New Mexico was formed in 1850 out of the country ceded by Mexico to the United States, with the addition of a portion of that claimed by Texas.

Surface, Hydrography, &c.—The Territory of New Mexico, bounded on the Pecos river, and the east by the same, is divided into the two distinct sections, which will probably at some future day be separated into two distinct territories or states: the one comprising the country occupied by the great river, and the other containing the Rocky Mountains. The former, or west of those Mountains. The former, or west of those Mountains.
20 miles wide, formed by the Rio Grande del Norte, traversing it from north to south. The western range of the Rocky Mountains bears various names, as the Sierras de Anahuc, de los Miembros de los Guatils, Mogollon, Madre, &c.; but the name now most commonly given to the greater part of it is the Sierra Madre. Many of the most northern summits of this range are covered with perpetual snow, and may be from 9000 to 18,000 feet above the sea. The southern part isn't much elevated, and the eastern range, which runs nearly parallel to the other, is known in the northern part as the Sierra Obscura, and in the southern as the Sierra Sacramento, though the latter name is commonly applied to it throughout. These mountains rise very precipitously to their eastern plains, are black, and knobs variously disposed, with fertile valleys between them. Some of the northern summits of this ridge are also covered with perpetual snow, and the altitude appears to be on the whole somewhat greater than that of the eastern range. Pines generally grow on the higher mountains, oaks and occasionally oaks on the lower ones. The narrow tract bordering the Sierra Sacramento on the east is very elevated, and forms the western boundary of the extensive plain north-west of Texas. The narrow valleys by which the mountain streams reach the plain are often heavily timbered, and the soil appears to be fertile; but the intervening spaces have an arid soil, which is only covered with vegetation in the early part of the year.

The great valley which lies between those mountain chains forms the district known as New Mexico while the country belonged to the Mexican republic. It is a very elevated tract, the northern part being more than 5000 feet, and the mountainous portion especially, with 8000 feet above the sea. Through it as mentioned above flows the Rio Grande del Norte. The surface, especially in the upper part, is greatly broken, and the soil throughout is sandy, and dry; but where irrigated it is generally very fertile. H.)-low Santa Fe about, is the most fertile part, and there and there crops are often obtained annually. This is the most populous and the only civilised part of the country, a large portion of it being occupied by the farms of the old settlers.

The country west of the Sierra Madre, forming nearly two fifths of the territory, is very much varied in surface. It is drained throughout by the Rio Colorado and its tributaries. The northern part is mountainous, and a large part of the eastern boundary is formed by rugged mountains. The interior is considerably diversified, well watered, and appears to be in many parts a fine agricultural country. The middle part is occupied by a great plain drained by the Rio Gila and its affluents, much of which is sandy and barren; but the latter has the advantage of being one of the most fertile parts of the country. The whole is occupied by Indian tribes: the Apaches inhabiting the east, the Shortly, the Navajos the north-east, the Pah-Utahs the north-west, and the Pimos the west and south-west.

The Rio Grande del Norte, or, as it is more commonly called, the Rio Grande or Rio del Norte, rises in the Rocky Mountains, near 40° N. lat., not far from the sources of the Arkansas and Colorado. Its course before it reaches the boundary of New Mexico is generally south-east, but throughout this territory it is nearly south. Its direct length from its source to its mouth in the Gulf of Mexico is about 1400 miles, but its course following its windings is full 3000 miles. Throughout New Mexico it is a rapid shallow stream, and has several important tributaries, but is navigable only by canoe, and though it is well fitted to supply mill-power, it is at present scarcely used except for irrigation. Its lower course is noticed under Mexico. The Rio Puerco is its only tributary of any consequence in this territory, though it runs for a considerable distance through a longitudinal valley west of the Rio Sagramento, has, owing to the arid nature of the soil, but little water. The Rio Colorado, which drains the western part of the territory, has its source in the Rocky Mountains of the Rio Grande till it enters New Mexico, when it bears more to the west, and so continues till it quits the territory and opens into the Gulf of California. The Colorado is believed to be navigable for a great distance, but the country through which it passes is such as to make travel by the river difficult. Several of its tributaries are also believed to be navigable for considerable distances. The most important tributary in New Mexico is the Rio Gila, which drains the great plain noticed above. It rises in the most southern extremity of the western range of the Rocky Mountains, and after descending into the plain, where it is joined by the San Francisco, an affluent which rises much farther north, it flows through the plain nearly west-south-west, with some conformity of configuration with the Colorado, about 35° 45' N. lat. It receives both tributaries on both its banks, but none appear to be of much consequence. The other more important tributaries of the Colorado in this state are the Nalapoa and the Yaquiella.

The mountains are composed of eruptive and metamorphic formations; the rocks enumerated consisting chiefly of granite, sienite, basalt, porphyry, &c., but Silurian and Carboniferous strata also seem to have been recognised. New Mexico appears to be rich in minerals, though its resources have not been fully developed. Gold has been found in many places. In the Santa Fé district the peasauny have long been accustomed to employ a good deal of their time in washing the river-sands for gold, and some gold-mines are worked. The Spaniards wrought several silver-mines, but none are now in operation. Copper is said to abound throughout the mountain districts, though only one or two mines are now worked. Iron is also abundant. Coal is said to have been found near the village of James south-west of Santa Fe, and in other places. Gypsum occurs in various parts. On the high lands between the Rio Grande and Rio Pecos and in other places are extensive salt-lakes, or salinas, whence all the salt used in New Mexico is obtained.

The climate differs considerably, but is on the whole temperate; its great characteristic is its dryness. There is a rainy season, from July to October; but the rains are seldom heavy, and never of long continuance. The winters are long, and not of much severity, and the Colorado is seldom frozen firm enough to admit the passage of cattle. In the lower part of the valley of the Colorado the summer temperature occasionally rises to 100° Fahr., but the nights are generally cool. Epidemics are scarcely known. The grain products are chiefly confined to maize and wheat; mesquite is raised in the central valley; peas and beans, onions, red pepper, some fruit, and tobacco are also grown. Agriculture is everywhere in a most primitive state. The only industry in which the country is on the raising of stock. Large numbers of horses, mules, cattle and sheep are reared, there being everywhere extensive pastures; but comparatively little attention has been yet paid to the improvement of the breeds, which are generally small and inferior.

Almost the only manufactures are those for which the natives have long been celebrated—namely, those of coarse and fancy blankets, in great request for the favourite national garment called the 'samps,' and the chequered woollen shawls for bedding and warming purposes. Most of the imported articles are received by the Missouri overland route by caravans, by way of Independence Santa Fé.

Of the 61,685 white inhabitants, above 58,000 are the descendants of the Spanish settlers, and all of them are Roman Catholics. The settlers from the older states and territories of the United States were only 761 in 1860. The natives appear to be an indolent but contented race, taking more of the character of their Indian than their Spanish ancestors. The more laborious work is assigned to the females; not only the household work, and a good deal of the field labour, fails to their lot, but the spinning of the blankets and woolen wares is chiefly done by them. Of the whites the Mexican is the most interesting. He is of various nationalities, and his family is numerous. They are chiefly what are called Aztec races, similar to those described under AMERICAN ANTIQUITIES, S. L. Several are found along the banks of the Colorado and the Grande rivers and their tributaries. The most celebrated are those known as Las Casas Grandes, on the Gila, noticed under AMERICAN ANTIQUITIES, S. 1, p. 98. Some of equal extent, called La Gran Quivira, occur near the Salinas, between the Rio Grande and the Pecos, about 100 miles S.E. of Santa Fé. The San Juan and San Pedro also contain several ruins, are said to be portions of an aqueduct 10 miles long.

*Divisiones, Towns, &c.*—New Mexico is divided into seven counties. Santa Fe is the political capital, and though there are several other towns, as they form no population as to be of little other than local consequence. Albuquerque, on the left bank of the Rio Grande, 76 miles S. from Santa Fé, is the only one which requires to be mentioned. It is said to have formerly contained 6000 inhabitants, but it has now little trade or population.
Santo Fé, the capital, is situated about 90 miles E. from the Rio Grande, in 35° 41' N. lat., 106° 1' W. long, on a wide plain surrounded by mountains, and at an elevation of 7047 feet above the level of the sea: population, 4846 in 1850. It is an old town, having been founded by the Spanish settlers in 1681, and consists of narrow irregular streets, with houses of adobe, some of them of a very old form and not having a central area. It contains two Roman Catholic churches, but no other public buildings of any note. The inhabitants are still nearly all of Spanish and Indian descent, but there are a few Americans who established two newspapers, one published three times a week and the other weekly. Santo Fé is a place of great trade, being the centre and depot of the overland route by way of Missouri. The climate is severe and little variable, and the town is said to be unhealthy.

The government of New Mexico is based upon the Act of Congress of September 9th, 1850, which established the Territory, and provided that every free white male inhabitant then residing in New Mexico, and all free white citizens of the United States who should subsequently qualify by residence, should be entitled to vote in all elections. The legislative assembly consists of a Council of 13 members, elected for two years, and a House of Representatives of 26 members, elected for one year, as the case may be, and is appointed by the president of the United States. A delegate to Congress is elected by the citizens.

NEWHAM. [Gloucestershire.]

NEWPORT, GEORGES, distinguished as a comparative anatomist and entomologist, was born in the village of Pen Y No, town of Keddington, in 1803. His parents were in humble circumstances, and with but little education he commenced following his father's business. He was indebted to a mechanics' institute at Newport, for first exciting in him a taste for the study of natural history. He became so well known for these pursuits that, when a natural history museum was opened at Canterbury, he was at once appointed curator. Without any guide or direct him, he pursued the study of animals in his own way; and was particularly fond of dissecting any fresh specimen that came under his notice. His love of anatomy and natural history paved the way for his entering the medical profession; and after having served his apprenticeship, according to the requirements of the Apothecaries' Society, with Mr. Wills, of York, and started in the practice of medicine at Lincoln, he entered the medical school at University, now University College. Here he attended the lectures of Professor Grant, and soon found that the work he had been pursuing in his spare time had prepared him to meet successfully the results of his labours to the world. His first paper was sent to the Royal Society, and was published in the 'Philosophical Transactions.' It was entitled, 'On the Nervous System of the Sphinx Liguistri, Linn.; and on the Changes which it undergoes during a Part of the Metamorphosis of the Insect.' This was speedily followed by other papers, which were read before the Royal Society, and published in the 'Philosophical Transactions.' The principal of these were entitled, 'On the Reproduction of Invertebrated Animals; ' On the Temperaturre of Insects, and its Connection with the Functions of Respiration and Circulation in this Class of Invertebrated Animals; ' On the Organs of Reproduction and Development of the Myriapoda; ' On the Structure, Relations, and Development of the Nervous and Circulating Systems, and on the Existence of a complete Circulation of the Blood in vessels, in Myriapoda and Macrouro Anarcha; ' On the Reproduction of lost Parts in Myriapoda and Insects.' He also published papers on myriad subjects in the 'Transactions' of the Linnean Society.

The labours of Newport, as a comparative anatomist, were chiefly confined to the insect tribe. Of all classes of animals, they present the greatest variety of forms, and the largest number of points of resemblance in the animals in which they are placed. They hence afford a wide field for research to the comparative anatomist. It is however few who are endowed with the patience and delicate manipulative skill which the dissection of their delicate organisms demands. From his youth Newport had taken a delight in investigating the structure of insects, and his paper on the nervous system of the Sphinx was received with astonishment, on account of the skill and labour it displayed. In this paper he not only gave a minute account of the nervous system of this insect, but pointed out the relation which existed between the parts of the nervous system in insects and other animals. In the same philosophical spirit he pursued his researches in other departments of insect life. His paper on the existence of a complete circulation of the blood in insects, showed the relation between these two functions long before the chemical changes by which they are accompanied were understood. In his papers also on the reproduction of limbs in articulata animals, and his researches into the development of the ovum in the same class of animals, will be found a series of researches bearing on all the modern progress of physiology. A résumé of his own researches upon insect anatomy and physiology, with those of other comparative anatomists, will be found in his article 'Insects,' in the ' Cyclopaedia of Anatomy and Physiology.'

While it is as an anatomist and physiologist that Newport takes a first position, his minor works and papers claim for him an equal portion of attention. As a naturalist, he was diligent in his observations on the habits of insects, as is proved by his prize essay on the 'Habits and Economy of Aethalia centifolia, the Sawfly of the Tarn.' Besides this paper he published many others on the habits of insects. In one of his works he describes of a new genus of Parasites, and worked out their history in the most accurate and beautiful manner. This paper was published in the 'Transactions' of the Linnean Society, and was entitled, 'The Anatomy and Development of certain Species of Ichneumonidae and Ichneumonidae, compared with their special Economy and Instincts; with Descriptions of a new Genus and Species of Bee-Parasites.' As a systematic entomologist, he devoted his attention to the description and classification of the insects, and his 'System of Entomology,' the most complete work on the subject, was published in the British Museum were arranged, and the catalogue descriptive of them published by the authorities of that institution was drawn up by him.

Newport early joined the Entomological Society, and contributed many papers to its 'Transactions.' In 1844 he was elected president of this society, and in 1845 he was re-elected. During the last few years of his life he had devoted great attention to the development of the ova in various kinds of animals. He published two series of papers on the development of the embry of the ovum of the Amphibia, and at the time of his death was engaged in drawing up a third. It was in consequence of pursuing this subject that he met with his death. In the spring of 1854, being desirous of obtaining some new facts on this point he journeyed to where he was exposed himself to the malaria of the ponds which these creatures inhabit, and on the 6th of April sank under a fever thus contracted.

All in all Newport became a member of the College of Surgeons in 1835, and was made an honorary fellow in 1843, he was too devoted to his scientific pursuits to follow his profession. But England has no position to offer his men of science, and during the latter years of his life he maintained himself on a pension of 100l. a year granted him by the government. Even the luxury of belonging to a scientific society has to be paid for, and out of his small pension Newport maintained his connection with the Royal Literary and Scientific Institute. He was also an honorary fellow, and to whose 'Transactions' he contributed largely. He was twice rewarded with the royal medal of the Royal Society, and was a member of the councils of both the Linnean and Royal Societies. His works were highly appreciated by Continental journaleers, and he was a member of several foreign societies. He was an amiable, retiring man, little known beyond the limited sphere of men who cultivate the sciences of comparative anatomy and physiology; but there will still remain the widely known that these sciences are more studied, and the true value of his researches be more widely appreciated.

NEWSPAPERS. In the 'Penny Cyclopaedia,' vol. xvi., an account was given of newspapers down to 1838. Of the United States, the newspapers are classed under the different countries may have varied somewhat, but their character remains unchanged, except that in France they have been brought still more under government control. In
that country they are liable to an official warning for any infraction of prescribed rules, and after a third warning the publication is suspended.

In treating of the origin of the newspaper, we stated in our previous article that the claim of 'The English Messenger', of which the first number was distributed in 1766, purporting to be published at the time of the Armada, were suspected not to be genuine. The suspicion was well founded. In 1839 Mr. Thomas Watts, one of the librarians of the British Museum, published a letter to Antonio Faci, Esq., in which he showed that the so-called 'Gazette de Paris', in 1631, are also unfounded, and that the earliest specimen of this branch of literature belongs "to Italy or to Germany." The claim of Germany is strengthened by the fact that Vien, dated sheets containing news were published as early as 1554.

Since the publication of the previous article, the abolition of the advertisement duty in 1853 (18 & 19 Vict. cap. 63); the total removal of the stamp duty in 1855, or at least reduced to a nominal amount on paper of a size and purpose, giving a mark of extent to the extension of newspapers in the United Kingdom. In London there are now (April 1858) published 11 morning papers instead of six. The 'Times,' which usually consists of 16 pages, or two sheets, each consisting of a full impression of one penny's postage, which gives the privilege of circulating by post for fifteen days (18 & 19 Vict. cap. 23); and the introduction of machinery, by which from 10,000 to 15,000 copies can be procured at a penny a sheet, giving a market impulse to the extension of newspapers in the United Kingdom. In London there are now (April 1858) published 11 morning papers instead of six. The 'Times,' which usually consists of 16 pages, or two sheets, each consisting of a full impression of one penny's postage, which gives the privilege of circulating by post for fifteen days (18 & 19 Vict. cap. 23); and the introduction of machinery, by which from 10,000 to 15,000 copies can be procured at a penny a sheet, giving a market impulse to the extension of newspapers in the United Kingdom.

Of the others, the 'Globe,' the 'Sun,' and the 'Shipping and Mercantile Gazette,' are of 4 pages, price 4d. The 'Express' and the 'Evening Herald' are branches of the 'Daily News' and the 'Morning Herald,' price 5d. and the 'Evening Star,' price 1d., is an evening edition of the 'Morning Star.' The 'London Gazette' and the 'Patriot,' the organ of the Independent and Baptist dissenters, are published twice a week. There are also various Tracts for the times, and pamphlets on the 'St. James's Chronicle,' the 'Monetary Times,' and the 'Record,' are published three times a week. Of weekly London papers there are altogether 111, but this includes literary papers, such as the ' Athenaeum,' the 'Literary Gazette,' and the 'Literary and Philosophical Repository,' and various city, commercial, and miscellaneous publications, such as the 'Solicitor's Journal,' the 'Builder,' and the 'Pawnbroker's Gazette,' but they are all essentially newspapers, though not all political. One remarkable feature is the existence of a considerable number of local papers in London, the 'City Press,' the 'Clerkenwell News,' the 'Islington Gazette,' the 'Islington Times,' the 'Holborn Journal,' the 'Marylebone Mercury,' and several others.

These are chiefly papers devoted to local affairs and advertisements, some of them covering a great number of subscribers, and some being published at a halfpenny. Some of the other weekly papers are conducted with a large amount of literary and political talent, and are of a higher price, such as the 'Examiner,' the 'Speculator,' the 'Saturday Review,' the 'Press,' the 'Weekly Spectator,' the 'Oxford Review,' and the 'Scottish Review,' and a variety of intelligence, and some of them reach a circulation of upwards of 200,000. Among those which reach a high number are some of the illustrated papers, such as the 'Illustrated London News,' 'The Illustrated Times,' &c. There are many other periodical publications, such as 'Household Words,' 'Chambers's Journal,' &c., which, as they do not contain news, are not included among newspapers. Of local newspapers published in England there are 411, and in Wales 39. Many of these are penny papers, which are mostly published in the smaller towns; but Birmingham has two daily papers and Liverpool one at that price. There are 131 newspapers published in Scotland, and the prices vary from a penny, of which price there are none in Edinburgh, instead of the penny stamp, but in Ireland there are 123 published, but only Belfast and Dublin have any papers so low in price as a penny. In the Isle of Man and the Channel Islands, there are published 13 daily newspapers, and the three four-bore newspaper stamp, and the other four an affixed postage stamp.

By the Act 18 & 19 Vict. cap. 27, any periodical publication, published at intervals, not exceeding thirty-one days, of which the price does not exceed the prescribed superfcies, may claim to be stamped as a newspaper; but in the case the title must be printed on the top of every page, with the date of publication; and, when printed, must be folded so as to show the stamp denoting the duty. Newspapers to be sent abroad by post may be registered at the General Post-office, for which a annual fee of 5d. is charged, the year always terminating on the 30th of June. It is not absolutely necessary that the newspaper should be registered, but the English Post-office then charges 2d. in addition to the foreign or colonial postage. Before a newspaper can be published a notice must be given at the inland Revenue Office, Somerset House, or at the place where the newspaper is printed, for the tax (5d. per number) will be given, in which is to be stated—the title of the intended paper quoted literally; the place where it is to be printed, giving the number of the house, the name of the street and of the parish in which it is situated, and the name and description of the occupier of the house in which it is printed, like particulars respecting the place of publication if it differs from the place of printing; the Christian and surnames of the printers and publishers; the number of shares into which the property is divided whenever the number, exclusive of the printer and publisher, exceeds two; and the Christian and surnames, residences, and occupations of every proprietor, with the number of shares belonging to each when exceeding two, exclusive of the printer and publisher. This declaration is made by the printer or the proprietor or by two of the largest shareholders where the number exceeds two, who must also furnish two respectable householders as sureties against the publication of seditions, blasphemous, or personal libels, to the amount of 400l. in London and 300l. elsewhere. Newspapers in print and these securities are given subjects the proprietors to a penalty of 20l. The paper when published must have across the bottom of the last page or the last column, the name and surnames of the owner, publisher, and proprietor, the name of the printer and publisher, the place and year of publication, the date, and the price, under a similar penalty for neglect. A supplement must be not issued without the paper itself; and a copy of the paper, which is paid for, must be transmitted to the Stamp-office on the day of publication or within three days after, if issued by other means, or within three days, under the like penalty of 20l. for each offence; but the penalties can only be sued for by the Attorney-General or the Stamp-office.
The size and amount of stamp-duty for newspapers are defined as follows by the 16 and 17 Vict., cap. 65: Newspaper stamps are to be 1d. only, for a superfluity of print, on one side of the paper, not exceeding 2596 inches, whether published as a supplement or not; any other supplement to a duly stamped newspaper not containing a superfluity on one side of more than 1148 inches of print is to be subject to a stamp of one-halfpenny; and any transaction involving more than 3596 inches, to a duty of one halfpenny each, provided each be published on one sheet of paper only. Newspapers not stamped go by post at the book-post rate of a penny for 4 ounces, two- pence for 8 ounces, and then ascending by twopence for every 8 ounces contained in any quarter, and any number may be sent in one envelope open at the ends.

NEWT (Liatrispin punctatus). [SALAMANDRIE, p. 336.]

NEWTON. [Lancashire.]

NEWTON-ABBOT. [Devonshire.]

NEWTON-LIMAVADY. [Londonderry.]

NEWTOWNARDS, County Down, Ireland, a market-town, and the seat of a Poor-Law Union, is situated near the head of Lough Strangford, in 54° 36' N. lat., 6° 64' W. long., 12 miles E. from Belfast by the Belfast and County Down railway. The population in 1851 was 9567, besides 658 inmates of the workhouse. Newtownards Poor-Law Union comprises 16 electoral divisions, with an area of 302 square miles, and in 1851 of 56,561. The town, pleasantly situated in the midst of rich, fertile, and well-watered countries, and was well built. In the Market-square and principal streets are many good houses. The parish church is a handsome building, erected in 1817. There are chapels for Roman Catholics, Primitive Methodists, and other denominations. The old parish church, erected in 1632, a large building with a handsome spire, is now used as a court-house. There are a market-house, a bridge, and a Union workhouse. The weaving and embroidery of muslin afford a considerable amount of employment, and petty sessions are held. Fairs are held on the second Saturday of every month, and on January 28th, May 14th, and September 23rd. Near the centre of the town is an octagonal structure, with canopied seat and pedestal of Portland stone, erected in 1636. Newtownards was incorporated by James II., and returned two members to the Irish Parliament.

NOAMI, LAKE. [AFRICA, 2.]

NIAGARA. [Canada, 2.]

NICEA (Nikèa), an ancient ruined city in Bithynia, in the north-west of Asia Minor, the site of which is marked by the Turkish village of Isî-kik. It stood on the eastern shore of the Lake Ascania, and was built or restored by Antigonus, son of Alexander the Great, and it was called Antigonea. The name was subsequently changed by Perdiccas, in honor of his wife, Nicaea, daughter of Polomenus, king of Egypt. The city became early the seat of a Christian bishop. It was destroyed by an earthquake in the latter end of 4 a.d. 255, but it was soon repaired, and the emperor Theodosius II., by the Greek Nicephorus Melissenus, the Turks, under Sokman I., took the city (1080), which was made their headquarters till 1097, when Godefroi de Bouillon, at the head of the Crusaders, took it after a siege of 36 days, and it was again united to the Greek empire. Two years after the establishment of the Latin empire in Constantinople (1204) Theodore Lascaris made Nicaea the Greek capital, which it continued to be till 1261, when in the reign of Michael VIII., the Turks conquered the city (1261), and before, Constantinople was recovered by the Greeks. In 1333, after an obstinate and bloody siege, the Turks, under Orkan, again took Nicaea, which they made their capital. After the battle of Angora (June 30, 1409) it was taken and pillaged by the followers of Tamerlane. In 1443 it joined in a conspiracy to put Mustapha on the throne of his brother, Amurath II., whereupon the latter reduced the city to obscurity, and had his brother and the chief conspirators strangled in his house.

Sir Charles Fellowes, who visited the site of Nicaea, says that the walls form a circuit of four miles. These walls are strengthened with towers. One part is built or repaired with masonry of great height, from an ancient temple; another part is built with Roman brick. The brick, of late age, marked with the sign of a cross and ill-cut inscriptions, showing the repairs made in Christian times; the remaining parts are built of immense stones cut to fit into each other in the cyclopean style. Four large majestic gateways with arched entrances still exist in an almost perfect state, but the inscriptions that once covered them have been nearly altogether effaced. Among the existing remains are many inscribed stones, copies of which are given in Sir Charles Fellowes' 'Asia Minor.' Among the ancient has been the temple of Apollo, the temples of the Dioscuri, and the statues; and ruins of an early Greek theatre, 'of extremely good workmanship, and colossal, the stones being some nine and others fourteen feet in length.' Ruins of mosques, baths, and houses are seen among the gardens and corn-fields of this great plain. The ancient has disappeared, and the village of Isî-kik, which stands in the centre of the ruins, is a small church, used by the Greeks for their worship, with Mosaic floor and ceiling of the Byzantine age. Every fence, trough, or paving-stone in the village and its neighbourhood is a fragment of good sculpture are built into the houses. A Roman aqueduct still conveys water to the town from the neighbouring mountains. In the lake, the waters of which are of transparent clearness, are the remains of an ancient landing-place.

In the history of the church Nicaea is memorable as the place in which the first and seventh ecumenical or general councils were held. The first, held in 325 (June 19 to August 25), in presence of the emperor Constantine and presided over by Osiris, representative of Pope Sylvester, condemned the doctrines of Arius, maintained the divinity of Christ, and declared the consubstantiality of the Son of God with his Father to be an article of faith. The second council, held by Osiris, is that the Nicene Nicenum, that is, Nicene or Nicene Creed, still in use. This council also passed decrees for celebrating the festival of Easter on the same day throughout Christendom. The seventh council was held in 778 (September 24 to October 23) and signed by 377 bishops, condemned the Iconoclasts, and explained the worship of images.

(Fellowes, Asia Minor; Art de Versar les Dates.)

NICARAGUA, Republic of, of Central America, occupies the high mountains on both sides of the oceanic basin of the Bay of Conchagua on the Pacific, and back to the Mosquito territory. It may be taken generally as lying between 10° 45' and 14° 10' N. lat., 84° and 87° 40' W. long., and as bounded E. by the Mosquito Territory; N. by the republic of Honduras; W. by the Pacific Ocean; and S. by the republic of Costa Rica, but the eastern boundary is really undefined, Nicaragua refusing to acknowledge the right of the King of Mosquito to the tract lying along the Caribbean Sea. The area, consequently, of the republic does not probably exceed 35,000 square miles, but that claimed is of course much greater. The population may be about 300,000, the chief part of whom are ladinos, or mixed Indians and Spaniards.

The coast along the Pacific from Salinas Bay to the Gulf of Conchagua bears nearly north-west. It is throughout rocky, and has some harbours of much value. That which may now just be regarded as the most important, from its being the Pacific port for the Nicaragua route connecting the Atlantic and Pacific Ocean, is San Juan del Sur, north of Salinas Bay, which is formed by two promontories between 400 and 600 feet high, having an entrance above 14° 30' N. lat., 86° 20' W. long., and is sheltered, and affords anchorage in from 2 to 10 fathoms water. About a mile from it is the nearly similar harbour of Nacacolo. Port Realejo, towards the northern end of the state, is also a very good and much larger harbour, and is that which, prior to the opening of the Nicaragua transit route, received most of the foreign vessels trading with the republic. There is a very narrow tract of tolerably level land along a good part of the coast.

Along the northern coast of the republic, at a few miles from the coast, extends a ridge of low volcanic mountains, highest at the southern end, and generally decreasing in altitude as we proceed northward: though one or two of the isolated peaks in the northern part are among the most elevated. The climate of the republic is unhealthy, and not much there is scarce any connection with the main ridge, though continuing in its general line of direction. The highest summits appear to be Omotepac, which forms an island in Lake Nicaragua (5100 feet above the sea); Memomoteb, at the northern
extremity of Lake Managua, about the same height; Mombo, between Lake Nicaragua and the Pacific (4500 feet); Nindiri, between Managua and Masaya; Feliz; El Viejo, and one or two others. Several of these are active volcanoes.

Another mountain tract, the Sierra Leon, in northwest Honduras, extends along the northern part of the country. This part of Nicaragua is traversed by several ridges, some of whose summits attain a considerable altitude. Between the ridges extend many good-sized valleys, the principal being the basins of the rivers San Juan,遮和Granada.

The remainder of the state belongs to the plain of Nicaragua, of which, however, the larger portion forms the Mosquito territory. This plain is but little elevated above the level of the sea; the tract of which communication occupies a large part of the Nicaragua section of it, being only 122 feet above the Caribbean Sea. Along the rivers it is wooded; the rest of the plain forms extensive savannahs, covered with a rich verdure, and presenting occasionally a clump of high trees. The climate being excessively hot and moist, the white races have not formed any settlements on this plain, and it is only inhabited by independent aboriginal tribes.

The few rivers which in Nicaragua fall into the Pacific, are of short extent and little consequence. Those falling into the Atlantic are longer and more important. Two considerable streams rise, as already mentioned, in the northern part of the republic, the Segovia and the Escondite; the sources of another, the Segovia, rise on the Gulf of Fonseca, the outlets of which are far apart—that of the Escondido being near the southern, and that of the Segovia towards the northern end of the Mosquito coast. The Segovia flows past the town of the same name, but both rivers belong more to Mosquito than to Nicaragua.

The rivers Rio San Juan, which forms the boundary between Nicaragua and Costa Rica, and falls into the Caribbean Sea, near 11° N. lat. It is by means of this river and the Lake of Nicaragua, that one of the two great lines of communication is proposed to be opened between the Atlantic and Pacific oceans.

The river San Juan is the only channel by which the Lake of Nicaragua discharges its waters into the Atlantic. The Lake or Laguna of Nicaragua is an inland sea, of a long and narrow form, being about 100 miles long and 40 miles broad where widest, without narrowing much at either end. It is the reservoir of a great extent of mountainous country, and is deep enough to be navigated by vessels of considerable size, having about 100 yards from the beach generally a depth of about 2 fathoms; and at a greater distance from 5 to 10 fathoms of water along the southern and western banks.

It is only very shallow along the north-east shore for a mile and upwards into the lake. It contains several islands, notably Monaguel. One of the three main western bank between Granada and Nicaragua, is remarkable for a high volcano, and for its fertility and population being inhabited by a numerous and industrious tribe of Indians, who have a small town, Moyapalpa, possess cattle, and are exempt in every respect from the Royal and other taxes; the eastern extremity of the lake; its breadth varies from 100 to 400 yards. About the middle of its course the San Juan receives from the south the Rio San Carlos, and lower down the Serapiqui. About 25 miles from its mouth the river divides into two arms, of which the southern and wider is called Rio Colorado; the other (the San Juan) enters the sea near the harbour of San Juan del Norte. The depth of water in the upper part of the course of the San Juan is considerable; the banks, even at low water, being nearly shelving; but as the river is shallow that rapids are produced, and it contains numerous islands. The lower portion of the river, below its bifurcation, is generally shallow. The mouth of the San Juan has a bar with seldom four feet of water over it. The winding course of the river is somewhat under 100 miles. On the Pacific side there are, however, greater obstacles to the communication between the two oceans than that presented by the channel of the San Juan. At the narrowest part the distance between the coast is only 15 miles, and the gulph is less than 10 miles, but the hills upon it rise to between 400 and 500 feet, presenting a formidable barrier to the construction of a canal, while the difference of level between the lake and the sea is 162 feet. The waters of the lake would be well suited to convey the passengers and goods from Nicaragua to San Juan del Sur on the Pacific. During 1854 a very large number of passengers and goods came from California adopted this route, and it was asserted in some of the advertisements of the line published in New York, that not only was "the Nicaragua Transit route the shortest, safest, and by far the most comfortable and healthful," but that passengers by it had "to travel but 13 miles of land carriage over a good macadamised road." Before the establishment of this route communication had been maintained between the Atlantic and the towns of Granada and Nicaragua, by the river San Juan and Lake Nicaragua, by means of flat-bottomed vessels called piraguas, of from 5 to 10 tons burden. The passage from Granada to San Juan del Sur by means of piraguas costs 10 dollars. The piragua in about 8 days, whilst the return passage being against the stream, occupies from 12 to 15 days. It has been proposed by some as more advantageous to unite the Lake of Nicaragua with the Pacific, by means of a small canal from Granada to San Juan del Sur. But this canal would be more than twice as long as the other; in addition to which, the Tepitapa, which unites the Lake of Nicaragua with that of Managua, must be rendered navigable. The lake of Managua is 30 miles long, and fifteen miles broad in its widest part. It is deep enough for vessels of considerable size; but the Rio Tepitapa, which brings down the water from the Lake of Nicaragua, and is about 25 miles long, has falls which, in the dry season, are from 6 to 8 feet high, and also several sand bars. These obstacles could only be avoided by a canal cut through the level ground on the northern side of the Rio Tepitapa.

The climate of the Plain of Nicaragua as stated above, is hot and moist, and so unhealthy as to have caused it to be left to the care of disease. The thickly wooded banks of the San Juan River are no exception to this observation. The shores of the Pacific, where the population is densest, are also very hot and somewhat humid, but do not appear to be particularly unhealthy, and in the drier northern and southern districts there is no such difference. In the hilly districts between the coast and the western banks of the lakes are much milder and more salubrious, as is also the mountainous country of the north. There are regular dry and rainy seasons, as in other parts of Central America, the only difference being that the rains last somewhat longer, and fall in larger quantities.

The hilly districts of the country and the western banks of the lakes are much milder and more salubrious, as is also the mountainous country of the north. There are regular dry and rainy seasons, as in other parts of Central America, the only difference being that the rains last somewhat longer, and fall in larger quantities.
woods and hides are at present the chief articles exported. Cattle are among the principal sources of wealth, very large numbers of them being kept on the plains along the eastern sides of the lakes. Fish are plentiful in the lakes, in which alga and aquatic plants are common. Along the coast pearls used to be found. The mineral resources of Nicaragua have not been very diligently explored. Gold and silver have been found and worked, but not extensively; copper has also been found.

The manufactures are nearly confined to the coarser goods required for home consumption. The chief articles made are coarse cotton and woollen cloths; the cotton being dyed of a purplish colour, obtained from a shell-fish caught in the rivers. The Indians, in great request among the Indians, who prefer it to any European dyed goods on account of the greater durability of the colour.

Nicaragua is divided into five departments, which are named after their respective capitals:—Segovia comprises the north-eastern part of the territory; Leon, the north and north-western; Managua, the district south of Leon; Granada, that south of Managua; and Nicaragua, the most southern part bordering on Costa Rica. Leon is the political capital. The following are the principal towns; the populations are merely a loose approximation:—

Leon, the capital of Nicaragua, contained not many years ago, a population of 32,000 inhabitants, but the civil contests within the town have reduced it to half that number, and its present position, we are informed, is situated on a road which leads from the best-cultivated districts of the state to the harbour of Realajo, in 12° 26' N. lat., 86° 22' W. long. The city occupies a considerable area, and contains a cathedral, several churches, a university, Tribunal, alcaiceria, etc., in a very healthy situation.

Granada, on the north-western bank of the Lake of Nicaragua, population about 15,000, carries on some trade with Jamaica by means of the river and harbour of San Juan, contains several churches and convents; but has no features requiring further notice.

Managua, on the south bank of Lake Managua, is a considerable place containing 10,000 inhabitants. Managua, some little distance S. of Managua, has a population nearly equal to it, but almost all Indian, who is engaged in commerce with the adjacent populous country, and in the manufacture of the various articles of domestic requirement in which they display much skill.

Nicaragua, about two miles from the west bank of Lake Nicaragua, contains, with the suburb of San George, some 15,000 inhabitants, and is surrounded by a district noted for its fertility, especially in caoca and grapes.

San Juan del Sur, on the Pacific, S.W. of the town of Nicaragua, has a few inhabitants, and is considered as a port or a selection as the Pacific port for the Nicaragua line of communication between the two oceans. The harbour, as already mentioned, is small but convenient, and possesses good anchorage.

Segovia, on the Rio de Segovia, is a small place, whose only claim to notice is that of being the capital of the department of Segovia, the least populous section of the republic. The country around is fertile and healthy, and its mineral wealth is believed to be considerable.

Nicaragua is nominally a Republic with a senate and a chamber of deputies, but the government is really vested in a dictator with the title of Supreme Director. After the declaration of independence and the formation, in 1828 of the republic of Central America [Granados, 1. 107. S. 3.], Nicaragua formed one of the federal states until the dissolution of the union, when, like the other states, it became an independent republic; and, like them, all hopes of its progress have been since arrested by constant internal discord.

NICOLAS I., PAVLOVICH, Emperor of Russia (styled also Czar and Autocrat of all the Russians), was born in the city of Petersbourg, July 7, 1796 (June 25, Old Style). He was the third son of the late Emperor Paul I., having been the first son, and the Grand Duke Constantine the second son. His mother, Sophie Dorothea, a daughter of Friedrich Eugen, duke of Würtemberg, when she became the second Empress of Russia, became also a member of the Greek Church, and, as is the usage, changed her name to that of Maria Fedorowna.

The Emperor Paul having been assassinated March 23, 1801, Nicolas was left entirely to the care of his mother, who appointed General Jemader his governor, and selected the Countess Liven and the German philologist Adelung as his principal teachers in languages and literature, and Counselor Storch as his instructor in general politics and other sciences and arts suitable to his rank and station. He acquired a knowledge of the French and German languages with as much facility as the Russian, and early manifested that preference for military display, military tactics, and the art of fortification, which distinguished him through life.

After the termination of the great European war in 1814, Nicolas was sent to travel, and visited some of the principal battle-fields. In 1816 he came to England, where he met with a cordial reception. He afterwards made a tour in the Netherlands, Belgium, France, Germany, and Italy. In 1817, he married Frederica-Louisa-Charlotte-Wilhelmina, eldest daughter of Frederic William III., king of Prussia, and sister of Frederic William IV., the present king. She was born July 13, 1796, and her distinguishing name was Charlotte, but on her marriage and entering the Church she assumed the names of Alexandra Feodorowna.

The Emperor Alexander I. having no issue, his next brother Constantine was the legitimate heir to the throne; but, by a document signed August 25, 1826, Constantine renounced his rights, giving to himself the dignity of Viceroy of Poland; so that, when Alexander died at Taganrog, December 1, 1825, Nicolas immediately succeeded him. He did not however become emperor without a struggle attended with much anxiety and bloodshed. The prince had not yet organised a considerable force before the death of Alexander among the officers of the Russian army and those of the nobility who were friendly to a constitutional government; and the soldiers and people were taught to believe that with the destruction of the revolutionary principles of France could be achieved by forcible means. When the troops were assembled in the great square fronting the Imperial Winter Palace of St. Petersburg, in order to make a manifestation of their allegiance to the new emperor, the ceremony was about to commence, stepping forward out of the ranks, denounced Nicolas as a usurper, and proclaimed Constantine as their rightful czar. The soldiers followed their officers, with cries of "Constantine and the Constitution!" Milardo, with the governor of St. Petersburg, a veteran follower of Nicolas, the army, and the archbishop, in his ecclesiastical robes, endeavoured to suppress the hostile demonstration, but in vain, and the people showed signs of sympathising with the troops. At this critical moment Nicolas called out, boldly confronting the officers and soldiers, called out with a loud voice, "Return to your ranks—obey—kneel!" The czar's majestic form and undaunted bearing, his pale but calm and stern countenance, and the reverence with which the Russians gazed upon him, produced a powerful effect upon the soldiers to kneel and ground their arms. The first outbreak was thus checked, but the conspiracy was not suppressed till artillery and musketry had poured freely their missiles of destruction among the gathering masses of the insurgents; and though the officers and other leaders of the conspiracy were executed. Others were sent to the mines of Siberia, where Nicolas continued their punishments with unanswerable severity. He was crowned at Moscow with great pomp and ceremony, September 3, 1826; and at Warsaw, May 24, 1829.

Soon after his coronation, in 1826, the Emperor Nicholas commenced a war with the Shah of Persia, which lasted till the victory over the Persians by Field-Marshal Paskevich, in which the Emperor was victorious, and which the Shah, besides undertaking to pay about three millions sterling, ceded to Russia the provinces of Erivan and the countries situated on the lower Kour and the Aras. This war between Russia and Turkey ensued in 1828, during which the power of speaking the Turks, which the Shah, besides undertaking to pay about three millions sterling, ceded to Russia the provinces of Erivan and the countries situated on the lower Kour and the Aras. In the campaign of 1828, General Diebich took the fortress of Silistria, defeated the main army of the Turks at Shumls, crossed the Balkan, and forced the surrender of the other Turkish forces. The war between Russia and Turkey ensued in 1828, during which the power of speaking the Turks, which the Shah, besides undertaking to pay about three millions sterling, ceded to Russia the provinces of Erivan and the countries situated on the lower Kour and the Aras.

On the 29th of November 1830 an insurrection broke out in Poland. The Polish troops having joined the insurrec-
tionists, the Grand-Duke Constantine, as commander-in-chief, was allowed to retire from Poland with 8000 Russians. In January 1831 the Polish Diet declared the throne vacant, organised a national government under Prince Adam Car
tory, but the Russian administration was more efficient.

They assembled about 60,000 troops; but the Russian armies which advanced against them numbered about 130,000, and had about 400 pieces of artillery. The Poles fought bravely, and were successful in several actions, but sustained an enormous loss at the battle of Ostrolenka, May 26, 1831. The Prussian government prevented the Poles getting supplies of arms and ammunition across their frontier, while the Russians were allowed to have magazines within the Prussian territory. Drouot, the potent minister of foreign affairs, died in June, and was succeeded by Paskevich. Warsaw was besieged on the 6th of September, and surrendered on the 8th. The failure of this insurrection was disastrous to the Poles. The Emperor Nicolas treated them with rigorous severity: several were sent to the mines of Siberia, and many to serve as soldiers in the Caucasus; the Polish constitua
tion was formally abrogated; the chief universities were suppressed, and the libraries removed to St. Petersburg; and on the 17th of March, 1832, by a decree of the emperor, the kingdom of Poland was incorporated with the Russian empire.

In 1837 the Emperor Nicholas made a tour in his Trans
casussian provinces. He travelled with great rapidity, but reviewed the troops, gave dinners and a grand ball, and held a levee, which was attended by all persons of distinction in the provinces. He paid a visit of inspection to the fortress of Gummi, since named Alexandropol, near the frontier of Turkestan and Persia, and the same evening he reviewed the troops. It was then in process of construction, and is now a fortified position of great strength either for defence or offence against the Turks in Asia Minor. A desultory conflict was at this period carried on between the Russians and the Circassians, but in 1839 war was formally declared by Russia against the Circassians, and has continued with little intermission ever since. In 1844 the Emperor Nicholas paid a second visit to England, and was entertained by Queen Victoria at Buck
ingham Palace and Windsor Castle from the 6th to the 9th of June. In 1849 he sent a Russian army into Hungary in aid of the Austrians, and the subjugation of that country was accomplished in the month of August of that year.

The last and most important event in the reign of the Emperor Nicolas was the recent war with Turkey and the Western Powers. It was the only unsuccessful and disas
trous war in which he had engaged, and the reverses his army experienced probably occasioned a degree of excite
ment which contributed to its being the commencement of the period of the empress's ascendency, which is believed to have been the minister's menzinkoff in March 1833 demanding a right of protectorate over those subjects of the sultan who belong to the Greek Church. The claim was refused, and a Russian army was sent to Constantinople as a 'martial guarantee' for enforcing it. In October of the same year the Porte declared war against Russia, and applied to France and England for their promised aid. A Turkish army under Omar Pasha occupied Skhuli and the fortresses on the Danube; in November he threw a body of troops across the river opposite Wida, and fortified a position at Oltenita, on the left bank, which was retained till the termination of the war. The destruction of the Turkish fleet at Sinope in the same month was followed by the advance of a Russian army under Bagration into the Black Sea.

The English and French armies were next landed and encamped near Constantiopolit, whence they removed to the vicinity of Varna. In March 1854 the Russian army crossed the Danube, and besieged the fortress of Silistria, but after great efforts and an enormous loss of men was compelled to raise the siege on the 18th of June, and to retreat across the Danube. The Anglo-French army landed in the Crimea September 14, 1854; won the battle of the Alma; by a flanking movement won the battle of theerek in the Black Sea; and commenced the siege, which, after a severe struggle, the facts of which are well known, was terminated on the 8th and 9th of September 1855, by the capture of the town and the forts on the southern side of the harbour of Sebastopol.

Meantime, before this great feat had been accomplished, the Emperor Nicholas died at St. Petersburg on the 2nd of March, 1855, and was succeeded by the present emperor Alexander II. The Empress Alexandra survives him, and he has left issue four sons and two daughters: Alexander, born April 29, 1816; Maria, born August 18, 1819; Olga, born September 11, 1822; Constantine, born September 21, 1827; Nicolas, born August 8, 1851; and Michael, born October 29, 1835.

The Emperor Nicolas was upwards of six feet in height, muscular and well-proportioned, with handsome features. In his personal habits he was simple, abstemious, and inde
temperately industrious. He had a taste for the fine arts, and was a connoisseur of music, and a patron of the arts, but his favourite pursuits were connected with the military sciences and military operations. In his political principles he was proselytically despotick. He has been heard to say, 'Despotism is the glory of my government, and it suits the genius of my land.' The great objects of his public life were the increase of the power of Russia and the extension of her territories to the east, west, and south, by unscrupulous diplomacy, and, when that failed, by war. His grand purpose is now known to have been the possession of Constantiopolit. By means of that unrivalled military and political position, he trusted to have superseded the Sultan in his empire, and to have become the dominant power in Europe and Asia.

Nicolás, Sir Nicholas, was born on March 10, 1799, the fourth son of John Harris of Cornwall. He entered the navy early, and attained the rank of lieutenant on September 15, 1815, after having distin

cuished himself in the Trafalgar action, where he served in the Vanguard. As a child he was employed after the close of the war he turned his attention to antiquarian literature, and his first production was "The Life of William Davison, Secretary of State and Privy Councillor to Queen Elizabeth," published in 1825. He published a second book, "Memoirs of a Servant in the House of Lords," in 1829. He was also the author of "Tours in France and Germany," "Tours in the Levant," and "Tours in Spain," and was the editor of "The Life of Francis Davison," reprinted from the edition of 1608: 'The Lite

rary Remains of Lady Jane Grey'; 'Journal of the Embassy of Thomas Beckington to France in 1442'; 'The Siege of Carlowayck'; 'The History of the Battle of Agincourt'; 'Memoirs of the Civil and Military History of Portugal,' published in 1823; 'A Chronicle of London from 1088 to 1483,' from manuscripts in the British Museum; 'Memoir of Lady Fanshaw, written by herself'; and 'Memoirs of the Reign of Henry VIII.' The works which are thus mentioned, with annotations and other matters, as to be assumed the character of original works, are all highly valuable to the historical student. In 1896 he became joint

curator with Henry Southern of the new series of the "Retro

spective Review," of which only six numbers were published.

Among his most generally useful historical works are: 'Nottis Historica, containing Tables, Calendars, and Mis

cellaneous Information for the use of Historians, Antiquaries, and the Literary public', published in 1812; and for 'Lardner's Cabinet Cyclopedia,' under the title of 'The Chronology of History; containing Tables, Calculations, and Statements indispensable for ascertaining the Dates of His
torical Events, and of Public and Private Documents, from the earliest period to the present time,' 1855, a most valu
able work, which has been more than once reprinted. In his "Controversy between Sir Robert Grosvenor and Sir Richard Scrope in the Courts of Chivalry, a.d. 1366-1368," a magnifi
cent work of 1819, in four volumes, 8vo, he gives a clear and un
concealed history of the controversy, and his work was used as the basis of a large number of other works. He also published "The Lives of the Earl of Surrey, Sir Thomas Wyatt, Collins, Cowper, Thomson, Burns, and Henry Kirke White." In 1844 he published "The Despatches and Letters of Admiral Lord Viscount Nelson," in 7 vols. 8vo. He had also com
menced "The History of the British Navy," of which only 3 N
lived to complete two volumes. Among his numerous other works were several on the statutes of various orders of knighthood, for which in 1831 he was made a knight of the Hanoverian Guelphic Order, and in 1832 chancellor of the Ionian Order of St. Michael and St. George. After a life of industrious research in his profession, and in every one of which has great historical or professional merit, he died at Cape Coré, near Boulogne, on August 3, 1848.

NICOPOLI, NICOPOL, in Turkish 'Fethiyan-Kale', the ancient Nicopolis ad Istrum, a city in Bulgaria, in Europe, on the right bank of the Danube, 80 miles S.W. from Bukharest, 250 miles N.W. from Constantinople, and has about 10,000 inhabitants. The Osa on the Bulgarian side, and the Aluta or Cuma on the Greek side, is the chief town on this shore of the city. The city, which occupies one of the finest sites in the world, consists of two parts. The fortress and Musulman town, crowned by many shining minarets, stand on the summit of a lofty limestone cliff above the Danube, several hundred feet high, and surrounded by a ravine. It is a place however of little real importance as a fortress, for it is commanded by heights around it. On the opposite or eastern slope the houses of Bulgarians, Wallachs, and Jews rise in white clusters one above another like an amphitheatre. The Turch town is defended on every side by batteries and by a stout parapet rampart, for the protection of infantry; it is further defended by a castle or citadel. There are some large well-built houses, several mosques and baths, but in general the town is very poor. The new city of Nicopolis, especially on the eastern side, towards Sistova, is very beautiful; much of the ground around the town is laid out in gardens. Nicopolis gives title to a Greek archbishop and a Catholic bishop. Its situation on the Danube makes it a place of some trade.

Nicopol was founded by Trajan. Several patches of the ancient walls still remain. The sultan, Bajazet I., at the head of the Janissaries, defeated the Hungarians, commanded by their king Sigismund, and sided by the chosen troops in Europe, under the walls of Nicopol, Sept. 28, 1396. Sigismund had besieged the town for six days before the arrival of the Turks. The town has often suffered from the Romanians.

PULULARIISEAE, a sub-order of Plants belonging to the order Gasteromecetes, the alliance Phanaglae, and the class Thalagonia. It includes the genera Nicularia, Cynthus, Cuculba, Spharabolus, Thelebus, and Alatobulus.

NINEVEH. [NINAVUS, S. 1.] Since M. Bottet's first discoveries were made known to Europe still greater additions to our knowledge of Nineveh have been made by Dr. Layard, who spent much time in making excavations in the great inclosure near the Tigris, before mentioned. Here, in the course of his discoveries, he has unearthed the papers of the great Assyrian monarchs; brought to light those colossal human-headed bulls, the kings, warriors, priests, and winged messengers, which form subjects of astonishment to visitors of the site. The great destroyers of Nineveh had beforehand eyes to read from long cuneiform inscriptions the pompous but inoffensive catalogue of Assyrian triumphs in war or in architecture. In a word, the discoveries of Dr. Layard have shed light upon one of the darkest periods of history, and laid bare before us the life, arts, and manners of a people of whom previously little more was known than the name. Colonel Rawlinson, Dr. Edward Hincks, and other distinguished British and Continental scholars have made great progress in deciphering cuneiform inscriptions.

NIQUBAI [ONIQUE, S. 1.]

NISI PRIUS. The nisi prius clause which gave rise to the use of this phrase in reference to the various matters mentioned under Nisi Prius, p. 341 no longer exists, the writ of certiorari which was formerly issued in every case having been abolished by the Common Law Procedure Act 1832. That statute has substituted for the ancient jury process a precept to be directed by the judges to the sheriff previous to the action, commanding him generally to summon a sufficient number of the parties, effecting in this way a considerable saving to the plaintiff.

NISI, or NISCH, a town in European Turkey, the residence of a pasha, is situated in a fine open plain on the Nissia, or Kizil Chu, a tributary of the Eurymedon, 60 miles S.S.W. from Widden, and contains about 10,000 inhabitants (4000 Mohammedans and 6000 Christians). Nissa occupies the site of Naisos, the birthplace of Constantine the Great; but nothing remains of its ancient glory.

The town is modern, and by no means remarkable for its beauty. The principal building is the Konak, or palace of the pasha. The defences works round the Turkish quarter on the right bank of the river, consist of well-built ramparts of great extent, with wattled parapets and a dry ditch. The town is defended by a citadel and a strong fort on the opposite shore of the river. It is surrounded by a trench and palisades. The Christian quarter, which is the largest part of the town, lies beyond theazaar, and is open to the plain. Nissa is now the chief town of the pashalik of Sophia; it is called Nisch by the Turks. It is the residence of a pasha and capital of a large pashalik of Western Asia Minor. As it is the key to military communications between Thrace, Bulgaria, and Servia, the fortifications of the town are mounted with a considerable number of guns of large calibre, and in the town there is also a gunpowder magazine and workshops. The Lowicz and the little Balkan, two ramifications of the Tesvich, and the little Balkan, two ramifications of the Hamsus, is one of the most beautiful, fertile, and well-tilled districts in Bulgaria. The town was taken by the Turks under the Sultan Amurath I. in 1389, on the march to the battle of Kosovo. A couple of miles above Nissa on the road to Sophia, the site of an action between the Turks and Serbs in the same year is marked by a tower of skulls, which is more terrible in name than in reality. It was constructed of stone and lime, but externally heads were imbedded in the mortar. Very few skulls now remain. The Christians having in the course of time removed almost all of them for the purpose of interment, but their places are marked by rows of round holes. The tower is 10 feet square, 16 feet high, and has a small wicket-window in the side wall.

The interior is said to be a favourite retreat of snakes and lizards. The Austrians took Nissa in 1737.

NOCTIULCA, a genus of Animals usually referred to the class Acoelophaga, [Acolephae]. One species only of this genus is known, N. serbica, which is found in prodigious numbers along the coasts of England, and is the most frequent cause in this part of the world of the phosphorescence of the ocean. It was first discovered by M. Surinam in 1810.

According to M. Suriray the Noctiulca is a spherical gelatinous mass, provided with a long filiform tentacle or appendage, presenting a mouth, an oesophagus, one or many stomas and ramified ovaries, and thus possessing a certain complexity of organisation. De Blainville confirmed Suriray's account, and placed Noctiulca, without doubt most erroneously, among the Diphyela. On the other hand, Van Beneden Verhaeghe and Doyers deny the relation of Noctiluca with the Acoelophaga—and conceiving its organisation to be of a much more elementary character—relegated it to the Rhizopoda.

To this doctrine M. de Quatrefages also attaches the weight of his authority in his valuable essay 'Observations sur la Céphalopode noctiluque', a letter published in the 'Journal of the Royal Society of Nat.' for 1850. M. de Quatrefages does not admit the existence of any true mouth or intestinal canal, and considers that the so-called stomachs are nothing but ' vacuoles' similar to those observed in the sea anemone, Cerebella. Kroneb was the first to describe the organ from which proceeds from the mouth of Noctiulca. Mr. Huxley has recently described this animal in the ' Quarterly Journal of Microscopical Science.' (Vol. iii.) He says—

"Noctiluca millitaria may be best described as a gelatinous transparent body, about 160th of an inch in diameter, and having very nearly the form of a peach—that is to say, one surface is a little excavated, and a groove or depression runs from one side of the excavation half way to the other pole of the body. (Fig. 1.) This is var. transversa, net. (Francois.)—From the body is drawn off the slender organ, the "Krohn. Where the stalk of the peach might be, is a filiform tentacle, equal in length to about the diameter of the body, and depending from it, and exhibits slow wavy motions when the creature is in full activity. I have even seen Noctiulca appear to push repeatedly against obstacles with its tentacle."

"The body is composed of a structureless and somewhat dense external membrane, which is continued on to the tentacle. Beneath this is a layer of granules, or rather a gelatinous mass, to which the granules are attached; through this mass the granules are scattered without any very definite arrangement. From hence arises a network of very delicate fibres, whose meshes are not more than 1-8000th of an inch in diameter, and which extend throughout the mass, becoming more and more open—into coarser fibres, which take a convergent direction towards the stomach and nucleus. All these fibres and fibres are covered with minute granules, which are usually larger towards the centre."
in case of a nonsuit, has ceased since the passing of the Common
Law Procedure Act, 1852, which provided a simple and
more rational method of putting an end to the action. (See
Reed’s Acts and Laws, 1852.)

It may be added here that the Crown, being theoretically
present in all our courts of justice, cannot be nonsuited; but
the Attorney-General, or his representative, may always enter
a non-suit by order of the Court in exercising their discretion.

NORTH AUSTRALIA is at present the designation ap-
plied to that part of Australia, comprising consider-
yably more than one-half of the island, which lies north of the parallel of 28° S. lat. This parallel forms the northern boundary-line
of the territory known as New South Wales, and the south
boundary of Western Australia remaining unsettled. Coburg Pen-
ninsula projects west-north-west from the mainland, between
Mount Norris Bay on the north-east and Van Diemen’s Gulf
on the south-east, a distance of about 60 miles. The greatest breadth of the peninsula is 15 miles, and it narrows progressively to the west and south-west, where it joins the mainland by a neck of land about 5 miles in length, and is 34 miles wide. On the north side of Coburg Peninsula is the deep inlet named Port Essington, which lies between 11° 43’ and 13° 50’ S. lat., 132° 8’ and 133° 18’ E. long. The inlet, at its entrance, between Point Smith on the east and Vashon Head on the west, is 7 miles wide, and extends south by east about 18 miles; its average depth is 25 fathoms. Between 5 and 12 fathoms from the entrance, and at the southern end it forms a large safe harbour, each of which extends inwards 3 miles, with a
width of about two miles; the depth of water is 5 fathoms,
with a bottom of stiff mud and sand. These harbours are
usually entered by large vessels, and are the centre of anchorage. The port forms one of the finest natural harbours
in the world; it may be entered with safety both by night
and day. Being within the range of the regular mon-
soon it is accessible to the Malay and Bengal trading prose,
and to the junks from China.

The soil of the peninsula is in general indifferrent, but in
many places it is good, principally on the low flats and hol-
lows, and near tracts which are swampy in wet weather.
The vegetation is only tropical, but during the dry season.
The north-west monsoon, which brings the rainy
season, begins about November. The rain during this mon-
soon falls in torrents, but seldom continues above two or
two hours at a time. The general range of the thermo-
meter at this season is from 75° to 95°, the midday heat being no lesser than the whole year is 63°, or
about that of the equator.

With the expectation that, if there were an establishment
on the north coast of Australia, it would be resorted to by
the traders of the eastern portion of the Indian Archipelago
and of the sable trade, and with a view of the exchange of
Indian commodities, a settlement was made in 1834 in
Apesley Strait, and called Fort Dandars, and another in 1837
on the Coburg Peninsula, and called Fort Wellington, but
both settlements were abandoned in 1838. In 1839 another
attempt was made, and the town of Victoria was founded
on the western shores of Port Essington. In 1846 the popula-
tion was stated to be about 60. The Malays did not settle
there, as was expected: the climate is unsuitable to Eu-
ropians, and the settlement has been abandoned.

The coasts, inlets, and islands of North Australia have
been surveyed and named, but of the interior hardly anything
is yet known. Melville Island, on the northern coast,
between 11° and 12° S. lat., 130° 20’ and 131° 34’ E. long.,
is one of the largest of the islands. The area is 1,400 square
miles. It is separated from Bathurst Island, which lies
west of it, by Apesley Strait, which is from 2 to 4 miles
wide and 46 miles long. From Coburg Peninsula it is sepa-
rated by Dandars Strait, which is 15 miles wide. The natives
lead a wandering life, living in the dry season on kangaroos
and other marsupial animals, and during the wet season on
fish, turtles, crabs, and other shell-fish. Their vegetables are
the cabbage palm and the sago-palm.

NORTH LEAVE HAVEN [SIMPSON R.]

NORTH-WEST PASSAGE. In the article North-West
Passage an account is given of the series of voyages under-
taken for the discovery of a passage westwards from the
Atlantic Ocean into the Pacific Ocean, through the
ship’s company, and around the North Pole, and the
passage is there brought down to the year 1838. We now add an account of

3 E 2

NOC 459 NOR

After describing minutely the structure of this creature, Mr. Huxley concludes—

"I have observed lead me to believe that
Nootillus has a definite alimentary cavity, but I am in-
clined to think that this cavity has an excreterary aperture
distinct from the mouth. The funnel-shaped depression in
the post-oral area in fact always appeared, when I could ob-
tain a view of it, as a circular eminence on the anterior aspect of the stomach. On one occasion I observed the sides of this process to be surrounded by fusiform transversely striated fibres or folds; I could not determine which.

Krohn states that he repeatedly saw the escut was voided "in the form of the colony, but of the body," but he
could not determine at what exact point, and he inclines to
think it must have taken place through the mouth.

I am equally unable to bring forward direct evidence on this
point, and my belief in the existence of the distinct anus is
found simply on the structural appearances.

"In front of and above the gastric cavity is the nucleus,
described by Verhoeffe and Krohn. This is a strongly
refracting oral body of about 1-400th of an inch in length,
which, by the action of acetic acid, assumes the appearance
of a hollow vesicle. The anterior radiating fibers pass from
it; the posterior from the alimentary canal.

Quaratges and Krohn consider that a process of
fission of the mouth is the birth of Nootillus also; both of
these observers having found double individual bodies.

On the contrary, in the division of the body is
preceded by that of the nucleus. I have not had the
good fortune to meet with any of these forms, and the only indica-
tions which I have noticed of the process are a certain
appearance of a number of granular vesicular bodies, of about
1-900th of an inch in diameter, scattered over the surface
of the anterior and inferior part of the body.

Such is what repeated examinations lead me to believe
is the structure of Nootillus; but if the preceding account
be correct, it is obvious that the animal is no Rhizopod, but
must be promoted from the lowest ranks of the Protosor to
the highest.

"The presence of a dental armature, and of a distinct
anterior aperture, are structural peculiarities which greatly in-
crease the affinity to such forms as Colpoda and Para-
macum, indicated by Krohn. Nootillus must be regarded
as a gigantic Infusoriam with the grooved body of Colpoda,
the long process of Trachelas, and the dentinal armature of
Nasutha united in one animal.

"On the other hand, the general absence of cilia over
the body, and the wide differences in detail, would require the
consideration of at least a distinct family for this singular
creature.

In the same volume of the Microscopical Journal is an
account of this creature by Dr. Woodham Webb, of Lowestoft.

NOCTUA, a genus of Insects belonging to the Nocturnal
Lepidoptera. Lycidae, and within this family, in the sub-
family Nolaneace. A natural order of Plants, having erect
or prostrate stems; alternate leaves without stipules. Flowers
usually showy; calyx 5-parted, valvate in maturation: corolla
monopetalous, with a pistil-like ovary thickened in the
styles; stamens 6, equal, inserted into the tube, alternate
with the segments of the corolla; anthers oblong, 2-celled,
bursting longitudinally; pistil composed of several carpels,
either distinct with a single style, or partially combined into
several nectaries, with a single style seated on a succulent disc;
 stigma somewhat capitate. Fruit inclosed in the permanent
caixy, constructed like the pistil; pericarp woody, often
a little succulent: seeds ascending, solitary; embryo curved
with either straight or double cotyledons in the midst of a
small quantity of albumen; radicle next the hilum. This
little order is remarkable for the various modes in which its
carpels are disposed without ever being consolidated. In
one genus there are but 6, and they are distinct; in another
there are 90 combined in fours, in which the combination is
irregular though the number remains 20, and in others they
are all wholly distinct. The species are all South American,
and chiefly from Chili. Their uses are unknown. There are
6 genera and 11 species.

NONSUIT. The statute establishing the County Courts,
9 & 10 Vict., c. 93, has established one exception to the
general rule that a plaintiff cannot be nonsuited against his
will, by expressly authorising the judge to enter a judgment
of nonsuit in a case of a non-suit. The practice of giving
judgment in the Supreme Courts, as
the subsequent voyages of exploration, and also of the expeditions sent out in search of Sir John Franklin and his associates.

In the year 1845 the British government sent out another expedition to the Arctic Seas for the purpose of discovering the North-West Passage, under the command of Sir John Franklin. They sailed from the Thames on the 23rd of May, and on the 25th of July were spoken by the Prince of Wales whaler at the entrance of Lancaster Sound. In consequence of the ships not having been afterwards seen or heard of, a series of searching expeditions were successively fitted out and sent to the Arctic Seas, all of which failed in the main object of finding the missing ships or their unfortunate crews, but one of which discovered the long-sought secret of a North-West Passage.

In 1848 the Enterprise and Investigator, under the command of Sir James Ross, were sent out, and reached Lancaster Sound on the 28th of August. They were not able to get farther west than Leopold Harbour, near the entrance of Prince Regent's Inlet, 73° 6' N. lat., 90° 12' W. long., where they wintered. After the ships were liberated from the ice, they were swept eastward by a mass of drift ice into Lancaster Sound, and Sir James Ross brought his ships back to England early in November 1849. In 1848 Sir John Richardson and Mr. Rae made a voyage in boats from the mouth of the Mackenzie River eastward, but without success.

Another searching expedition was fitted out by the British government in 1850. Captain McClure was appointed to the command of the Enterprise, and Captain Clavering to that of the Investigator. The two ships left the Thames January 10, 1850, and sailed in company round Cape Horn, where they encountered first Barrow, and then north-eastern extremity of Behring's Strait, August 5, 1850, and then bore to the east, just keeping clear of the American coast. Captain Clavering having failed to force his way through the pack-ice of Behring's Strait, sailed for Hong Kong, where he wintered. Captain McClure reached Cape Parry on the 6th of September. From this point high land was observed to the east-north-east, and named Baring Island, and two days afterwards, still farther to the east-north-east, more land was observed, and named Prince Albert Land. This land is continuous with Victoria Land and Victoria Island, and extends northward to 72° 21' N. lat. The Investigator was then navigated northward through a channel which separates Baring Island from Prince Albert Land, and which Captain McClure named Prince of Wales' Strait. In sailing up this strait the Investigator several times narrowly escaped destruction, but on the 8th of October was firmly frozen in near the northern extremity of the strait, and remained there through the winter. Parties were sent out by the strait, and discovered a portion of Prince of Wales' Strait opens into Barrow Strait, and thus was made the first discovery of a North-West Passage.

On the 14th of July 1851 the Investigator was freed from the encircling ice and steamed southward. The Prince of Wales' Strait into Barrow Strait, but on the 10th of August, being then in 73° 14' N. lat., 115° 32' W. long., strong winds from the N.E. drove the masses of ice against the ship, and Captain McClure, thus baffled, resolved to sail southward back again down Prince of Wales' Strait. Having accomplished this, he sailed along the southern coast of Baring Island, and then northward along the western coast. At length, after incurring many risks and encountering difficulties, they ultimately have been enabled by a rare combination of indomitable courage, admirable seamanship, and scientific resource, the Investigator, having rounded the whole island except a portion of the north shore, was got to the station which Captain McClure named Mercy Bay, September 4, 1851. This station is on the northern side of Baring Island, in 74° 6' N. lat., 117° 54' W. long., on the south side of Barrow Strait. Here then was the discovery of a second North-West Passage; and had there been open water, the whole voyage into Baffin's Bay might have been easily accomplished, but as it was the great- gator was frozen up in Mercy Bay on the very day it was entered. The north side of Baring Island was ascertained to be the Banks' Land which Captain Parry saw from Melville Island.

Melville Island is distant about 60 miles N. from Mercy Bay, and in April 1853 Captain McClure sent a travelling party across the ice to it, who deposited a document there, giving an account of the proceedings of the expedition, and of the position of the Investigator. In April 1853, only a few days before Captain McClure had made arrangements for deserting his frozen-up ship, the document was discovered by Captain Kellett's officers, and Lieut. Pim, with a party of boats carrying provisions, were sent out to Melville Island, to Mercy Bay, and equipped with all necessary things. Captain McClure and his crew, the excitement of the meeting may be easily imagined. Captain McClure remained with his ship till the spring of 1854, when he and his crew were brought back to England by the ships belonging to Sir Edward Belcher and his company. The Investigator, as far as is known, still remains frozen-up in Mercy Bay.

Captain Collinson, after wintering at Hong Kong, passed through Behring's Strait in 1851, and followed very nearly the course of Captain McClure's voyage of 1850, and discovered a strait between Herschel and Prince of Wales' coast, whence he also was obliged to return. He wintered in 1851-2 in 71° 35' N. lat., 117° 35' W. long. The winter of 1852-3 was passed in Cambridge Bay, Wollaston Land, 69° N. lat., 103° 30' W. long. Still struggling on, the winter of 1853-4 found the Enterprise in 70° 8' N. lat., 145° 30' W. long. On the 15th of July, 1854, the Enterprise was released from the ice, when Collinson commenced his return voyage. He reached Point Barrow on the 9th of August, and Point Clarence on the 1st.

These expeditions may be more briefly noticed. In 1850 Captain Kellett with the Herald and Plover reached 72° 51' N. lat., 163° 48' W. long. In the same year the Advance and Rescue, two small brigs, were sent out under the command of Lieutenant William Dampier, and discovered a channel between Herschel Island and Victoria Island, and named the channel Dampier Strait, and placed under the command of Lieutenant de Haven. In August, 1850, Captain Ommanney and Captain Penny conducted travelling parties by order of Captain Austin, who commanded an expedition sent out by the British government, in the British seas. Captain Frank discovered that Sir John Franklin's expedition had passed the winter of 1854-5 at the mouth of the Wellington Channel, in a bay between Cape Riley and Beechy Island. Captain Penny also explored the Wellington Channel to a distance of 60 miles from the mouth, and discovered a strait between Herschel Island and Victoria Island, named after Captain Penny. In May, 1851, the Prince Albert, a small vessel, was equipped at the expense of Lord Stanley, and under the command of Mr. William Kennedy. The Prince Albert passed through Lancaster Sound, and wintered in Batty Bay in Regent's Inlet, on the east side of North Somerset. In March, 1852, Mr. Kennedy, with Mr. Ballot, an enterprising young French sailor, and a party of Kamichelle Indians, explored the Wellington Channel to a distance of 60 miles from the mouth, and discovered a strait between Herschel Island and Victoria Island, named after Captain Penny. They thus discovered a third North-West Passage, and proved that North Somerset is a large island, separated from Boothia Felix by the Brentford channel, which they named Ballot Strait, and found to be 15 miles long and 2 miles wide. They next travelled over the ice of Victoria Strait, then over Prince of Wales' Land due west as far as 100° W. long., then northward to the south-east angle of Ommannaney Bay, then eastward to Brown's Bay in Peel Sound, whence following the coast-line northward they arrived at Cape Walker, where the Prince Albert had wintered in 1850. May 30th, after an absence of 96 days, and having travelled on foot and with sledges 1100 miles.

Captain Inglefield, in the small screw-steam-ship Isabella, sailed from the Thames July 31, 1852. He proceeded along the east side of Baffin's Bay, and entering Whaleb Sound found that it contained two large openings to the north-eastward. He entered Smith's Sound at the head of Baffin's Bay, and on the 27th of August attained 78° 30' N. lat., 101° 30' W. long. The north coast there suddenly tending to the south, and the sound being of such a nature as to point its direction westward as far as the eye could reach. The Isabella returned to England in November, 1852.

A searching expedition under Sir Edward Belcher was sent out in 1852. He proceeded up the Wellington Channel, and
wintered in 76° 52' N. lat., 97° W. long. While here exploration with boats and sledges led to the discovery of various countries and lands. The west side of Western Greenland was named North Devon; the western side is Cornwallis Land, which is separated by a strait from Bathurst Land still farther west. A group of islands in 78° 10' N. lat., named for a French fishing boat, was seen by Sir E. Belcher in 1850, and the Pilot of the Belcher, from which the name is derived, was blown from the bow of a whaler on a desolate island. 

In October, 1854, Dr. Rae returned suddenly to England from the vicinity of Boothia Felix, for the purpose of announcing to the British government that he had obtained some relics which had belonged to Sir John Franklin's companions. He stated that he had met with some Esquimaux in Pelly Bay, who were in possession of watchs, silver spoons, telescopes, and other things which belonged to the officers and seamen of the Erebus and Terror. These he purchased for 100 dollars. But it is stated by some that the Esquimaux had informed him, that in the spring of 1850 about forty of the ships' crews were seen (not by Dr. Rae's informants) near the north shore of King William's Land, that the men were well clad, and had procured worn and emaciated, and had purchased a seal of the natives. The two expeditions which it was stated the Admiralty intended to send out in November 1854 were not sent. Lady Franklin, however, chiefly on her own expense, sent out an expedition in the Pery, under the command of Captain M'Clintock, which sailed from Aberdeen on the 1st of July, 1857.

The result of all these searching expeditions—of which we have only noticed the most important—was, that there was very little prospect of any of them being able to reach the Pacific Ocean, which the Antarctic Ocean be Mary be entered by the Atlantic, or the Atlantic Ocean from the Pacific, by which, the west coast of Barings Island, by the east coast of the same island, by Prince of Wales Strait, by Regent's Inlet by Bellot Strait into Victoria Strait, and probably also by Peel Strait into Victoria Strait. These passes, being all more or less encumbered with ice, may be of little or no commercial importance; but the long-sought North-West Passage has been discovered, many expeditions have been sent, but the islands and countries have been found and partly examined.

Besides the geographical discoveries which have been incidentally noticed in the course of this narrative, it has been ascended that there are three large islands in the Arctic latitudes, Dr. Rae, and Captain M'Cure, that Wollaston Land and Victoria Land are continuous, forming the south coast of the largest of all the islands of the Arctic Seas, the western boundary being Prince of Wales Strait, the eastern boundary Victoria Strait with its continuation Peel Strait, and the northern boundary Barrow Strait. The northern coast of this large island is deeply indented near the eastern end by Omnmanney Bay and Osborne Bay, so named from the explorers. North Somerset was also, as has been stated, a large island separated from Boothia Felix by Bellot Strait, previously called Brentford Bay; whilst Boothia Felix has been ascertained to be united to the American continent by an isthmus.

In many parts of these cold regions there is an extraordinary abundance of animal life, consisting of moose-deer, hares, ptarmigan, and other game. In 1891, Captain M'Cure says, "On the 1st of April we had 1000 lbs. of venison hanging at the yard-arms;" and in 1893, he says, "A supply of game has been kept up during the winter, which has enabled us to issue a meal twice weekly." It seems also to have been ascertained, that north of Smith's Sound and the Wellington Channel there is an extensive Polar Sea, compared with the North Atlantic, which was seen by Dr. Kane as well as by Captain Inglefield.

NORTHERN SOVEREIGNTY. This name has been given, but perhaps not definitely, to an extensive tract of country which was annexed in 1848 to the British possessions. It is a small tract of land on the west side of the Drachenberg Mountains, between the two great branches of the Orange River, the Ky Gareep and the Nu

Gareep, comprising a triangular area of about 50,000 square miles.

The Drachenberg Mountains, called also the Quatlaumba Mountains, run parallel with the eastern coast of South Africa, at a distance varying from 60 to 90 miles from the shore. They rise to a height of from 6000 to 8000 feet, which towards peaks, and rocky ridges, intercepted only by ravines and canals, and thus forming a barrier between Kaffiria and Natal on the east, and the Northern Sovereignty on the west. A secondary range, called the natives Malati, or the Peaks, runs parallel to the Drachenberg Mountains, and is intersected by ravines, and rocky ridges, and is thus forming an other barrier to the Malay, and the Northern Sovereignty on the west. A secondary range, called the natives Malati, or the Peaks, runs parallel to the Drachenberg Mountains, and is intersected by ravines, and rocky ridges, and is thus forming an}

The country immediately west of the mountain ranges is from 600 to 900 feet above the level of the sea, and consists of a series of wide plateaus, which, sloping gradually downwards towards the lower course of the Vaal River, terminates in plains of vast extent, sometimes containing numerous isolated and rocky hills, but generally quite flat and without trees. These vast wastes are for the most part without a single human inhabitant, but afford abundant means of subsistence to countless herds of antelopes, quagga, and other wild animals. All the rivers fall ultimately either into the Kafiria, or into the Vaal. The Vaal River rises between 26° 27' S. lat. 29° and 30° E. long., about 500 miles W. from Delagoa Bay, in an interior range of mountains bounding the great plains of the north, and flows south-west, then west, and afterwards north-west, till it joins the Ky Gareep. Its principal affluent from the north is the Caledon; from the south it receives the Stormberg River, the Orolgo, the Zeekoe Rivers, and other less of importance.

This portion of the continent, being remote from the sea-coast, receives its rain in thunder-storms, chiefly during the summer months, December and January, are the hottest; and there being no rain during the middle of the year, the climate and soil are then characterised by great dryness, though copious dews fall at night. The smaller rivers are dried up, and the ponds and lagoons are converted into swamps.

The White-Faced Antelope (Antilope albirostris), the Spring-Bok (A. eurhoch), the Gnu (A. gnu), and the Quagga (Equus Quagga) seem to be in the greatest abundance. They are often seen in countless herds covering an immense extent of the plain. The spring-bok is a large antelope, its horns are less numerous, and with buffaloes. Hyaenas are abundant. Lions are very common. The hippopotamus is very common in the larger rivers. Ostriches appear on the great plains, and in the mountains, and in the isolated hills of the interior. The Giqua, who are a mixed breed, arising from the intercourse of Europeans with the natives, are in considerable numbers. They are mostly settled along the banks of the Na Gareep and of the Kafiria.

The colony has been distributed into four districts—Bloomfontein, Caledon River, Winburg, and Vaal River. The principal town is Bloomfontein; situated in 29° 8' S. lat., 26° E. long., on the high road from the Cape Colony to Natal. It is about 360 miles N. from Graham's Town. It contains about 1000 inhabitants, has an Episcopal church, a Wesleyan Methodist chapel, and barracks. Smithfield, Winburg, and one or two other villages, are inconsiderable places. There are three or four mission-stations belonging to the British, French, and Prussians.

The country appears to be well adapted for sheep pasturage and the production of wool. The climate seems to have a favourable influence on the fineness of the fleece. Small quantities of merino wool have been found in the neighborhood of Smithfield.

When the Dutch inhabitants of the Cape Colony emigrated
from in 1836 and following years, they settled themselves at first in various parts of the territory which is now named the Northern Sovereignty. In 1886 a party of them went to Natief, where they were treacherously murdered by the warriors of the chief Dingan. [Nata, S. 2.] When the Dutch, who had conquered the natives and declared a republic, were obliged in their turn to submit to the English in 1849, the greater part of them fled into the Northern Sovereignty, where they founded the village called Winburg, and proclaimed a new Dutch republic. Little notice was taken of their proceedings till they began to expel from their farms the Dutch farmers who continued to acknowledge the British supremacy, and in 1845, under their leader Pretorius, prepared a large expedition to attack Adam Kok, a Griqua chief in alliance with the British. The chief applied to the colonial government, and two regiments were immediately sent to his assistance, who repulsed the revolutionary Dutch boers. On the 1st of February 1846, Sir Harry Smith, with the assent of the well-affected boers, erected the whole of the territory inclosed by the Ky Garoop and the Nu Garoop into a British colony. This led to another contest, in which Sir Harry Smith defeated Pretorius and his adherents on the 29th of August, 1846. Pretorius fled beyond the Vaal River, and the majority of the boers laid down their arms and submitted to the British government.

NORWOOD. [SARRT.] NOSE, one of the external apertures of the respiratory system and the organ for the sense of smell. The portion of the nose by which odours are perceived, lies deep back in the cavity to which the external apertures of the nostrils lead; the portion which is prominent upon the face serves merely as the apparatus for inhaling the air which is impregnated with the odour. The most essential parts of the organ are the olfactory nerves, which come off from the olfactory bulbs of the brain [Brain], and passing through numerous holes in the ethmoid bone, which is situated between the orbits and above and behind the nostrils, ramify on the external surfaces of that bone and the turbinated bones which form on each side the chambers of the nose. The sensitive terminations of the nerves are placed on the surface of a delicate and very vascular membrane which lines the whole cavity of the nose, and which is constantly kept moist by the secretion of a small quantity of mucus, in which the odoriferous particles are caught and for a time retained.

The sense of smell varies considerably, both in degree and in kind, in different animals. It is evidently possessed by insects and many others of the lower animals, but the organs by which they exercise it are unknown. In the higher animals its degree of acuteness is in general marked by the extent of surface of the ethmoid and turbinated bones, over which the olfactory nerves are distributed. In man this surface is proportionally smaller than in other animals, in most of which, besides occupying the greater part of the interior of the face, it is increased by peculiar branchings and convolutions of the thin layers of the bones. Each species has also a sense of smell in some degree peculiar to itself; thus herbivorous animals, though possessing the most delicate power of discerning the differences of vegetable odours, have no evident faculty of discriminating those of most animal substances; while the carnivora, on the other hand, can scarcely distinguish any others than the last. Each species has a fine sensibility for those substances which are of the greatest importance to its own existence, and thus obtains at once a knowledge of their presence in places concealed from all the other senses. Man possesses the sense of smell for a very large number of substances, but not in a very acute degree for any of them. The difference appears the greater between him and other animals in consequence of the neglect of the exercise of this sense which is common (except for particular purposes) in civilized society; but the American Indians and some of the northern Asiatic tribes, by their constant practice in hunting, are said to have acquired a power of scent scarcely inferior to that of the dog.

The olfactory nerve is appropriated exclusively to the sense of smell, and is incapable of perceiving pain or any other sensation. Of the peculiarities by which in different animals it is capable of perceiving only certain odours, we know no more than of the nature of those odours themselves, of whose existence we have no other evidence than that of the sense which they affect.

The sense of smell serves as an adjunct to that of taste, and is subservient in most instances to the same purpose, of providing proper and avoiding injurious food for the sustenance of the body. By it many animals seek out their food, and all select from that which they obtain; and much of that compound sensation which we regard as taste is really due to the smell, as for instance the sensation of the flavour of aromatic substances, which is completely lost by closing the nostrils while we are eating them.

For the full perception of odours it is necessary that the particles charged with them should be drawn with some force into the nose, and we may stand for some time in a very strongly smelling atmosphere without perceiving it if we breathe only through the mouth. The most acute sensation is obtained by the sudden inhalation of a large quantity, or by a succession of short and quick inspirations.

NOTONECTA, a genus of Insects belonging to the family Hydrocoris, of the order Hemiptera. N. glanca, the Water-Boatman, is one of our commonest insects. It is about half an inch long, and swims upon its back in order the better to seize its prey.

NUNEADES. [WALES.] NUSSEIRITE. [MINERALOGY, S. 1.]

NUTRIMENT, NUTRITION. [Food, S. 2; Trees, Organic, S. 1.]

NYCTAGINACEÆ, a small natural order of Hypogynous Exogenous Plants, belonging to Lindley's Cheenpodal Alliance. They have a tubular often coloured calyx, which separates from its base, the latter becoming a hard spurious pericarp. The species are annuals or perennials often with fleshy roots, or shrubs or trees usually arculate at the umid nodes. Mirabilis dichotoma, the Marvel of Peru of our gardens, may be taken as the type of the order. M. jalapa was at one time supposed to be the plant, yielding true jalap. This however is a mistake. [CONVOLVULACEÆ.] The roots of the plants of this order are generally purgative. They are natives of the warmer parts of the world in either hemisphere. They are tropical or subtropical. The order is related to Polygomesæ, Amarantheæ, and Cannabinaeæ. It contains 14 genera and about 100 species.
OAT. [Avr.]

OATH. The privilege long enjoyed by Quakers, Moravians, and Separatists, of giving their oaths upon solemn declaration, is by the Common Law Procedure Act, 1854, extended to all witnesses, who conscientiously object to be sworn. A willful false declaration in all these cases involves the party, by the provision of the statute, in the same penalties as perjury.

OCCUPATIONS OF THE PEOPLE. The importance of obtaining as specific and complete an account as practicable of the pursuits and employments of the inhabitants of this country has long been recognised; and in each decennial census of the present century it has been attempted, with constantly increasing efforts after greater fullness and precision, to ascertain the number and proportion of the persons engaged in agriculture, commerce, the various trades, manufactures, and professions. In the enumerations of 1811 and 1831, inquiries were instituted as to how many families were employed in, or maintained by, agriculture; how many by trade or manufactures; and how many which could not be brought under either of these designations. The answers to these inquiries were given with tolerable fullness. In 1831, it was resolved to ascertain, so far as could be done, the occupation of every male adult twenty years of age or upwards. On that occasion a form, containing a list of one hundred different trades and handicrafts, being those most commonly carried on, was forwarded to the overseers in each parish or place required to make a separate return, to be filled up with the number of males aged twenty and upwards; and the overseers were authorised to add to the list such additional trades as were not included in the printed form. But many anomalies and imperfections arose out of this plan; and it was therefore resolved, in 1841, that the enumerator, instead of using a prepared list of one hundred, or any other definite number of trades, should insert each man's description of himself opposite his name. This led to some curious results. In the more important manufactures, the subdivisions of labour entered in the schedules were so minute, that there were no less than 1235 distinct heads of employment (some of them, it is true, identical) in the cotton manufactures of Lancashire; and in 1831 the enumerators had entered only 568 for the whole of the country. In like manner, the London occupations, given as 420 in 1831, were 757 in 1841; and the occupations of Great Britain became similarly increased from 258 to 877.

In 1851, to use the words of the Registrar-General, to whom the management of the census of that year was entrusted, "it was considered important to extend the inquiry, so as to show, as nearly as was practicable, the number of men, women, and children in every trade and profession;" and it was further held to be desirable, notwithstanding the great additional labour entailed in abstracting and tabulating the results, "not only to take out the number of persons of each sex in each occupation, but the numbers at each quinquennial period of age: for without this information the relative salubrity of the professions, and a great variety of important questions, cannot be determined." The results of the inquiries instituted are embodied in a bulky but very able report, drawn up by the Registrar-General, which examines the subject as a whole and in detail from various points of view, and in numerous elaborate tables presents the results as digested after a vast amount of labour and consideration.

We are proud of the results obtained, selecting each as will illustrate various industrial phases of British population.

In looking at the tables with regard to the more general results, there are many interesting particulars which become developed. Here and there the total numbers for 1851, Great Britain and the small adjacent islands, is set down at 20,959,477, of whom 10,223,568 are males, and 10,735,919 females. One-half of this total is 10,478,738. Now this is almost exactly identical with the number (10,416,860) of those set down as the domestic appellation as husband, widow, daughter, grand-daughter, sister, niece, son, grandson, brother, nephew, child under tuition at home, child under tuition at school; that is, persons to whom no occupation whatever is attributed, but who are regarded as dependent on the head of the family for support. Regarded in this light, therefore, just one-half of the population have nothing and do nothing to earn a living; they are the home-members of a family; they may assist in domestic labours, but they do not work at money-getting employments. There are then left half the population, who either possess wealth already accumulated, or hold heads and heads in the acquisition of wealth; of this half, one moiety can, with a near approach to correctness, be divided into five equal parts, thus—

About 1,000,000 domestic servants.
1,000,000 employed in preparing the materials for dress.
1,000,000 employed in making dress.
1,000,000 ordinary agricultural labourers (males).
1,000,000 other persons; male and female, living by farm and field operations.

Most of these numbers are slightly over the million. If we suppose the two millions of farmers, gardeners, and in-door and out-door farm servants of every kind, to be all employed in raising food (and this is not such a wide departure from the truth as to vitiate such general results as we have now in view) it brings us to this conclusion: of the total population, about 21,000,000, there are—

Of family dependents, having no definite occupation.
Of persons supplying dress, food, or domestic service.
Of persons employed in all other occupations.

When the Commissioners came to prepare their vast tables of the distribution of occupational classes, by townships, counties, districts, and towns, they had to determine how many different occupations should be given in each table. If the whole 1057 occupations, presently to be advertised to, for males had been tabulated for each and all of the topographical sections, the volumes would have been numerous and bulky beyond all endurance, the labour and expense enormously great, and the practical value very questionable. The list was therefore weeded. Several occupations were omitted which are only very limited in their geographical distribution, and all were omitted in which the total number of persons is very small. Different degrees of minuteness were adopted, according to the nature of the tables. Thus, one table, for the whole of Great Britain, gives all the 1057 occupations; another, for a county, divides the workers who are above and those who are below 20 years of age, but not distinguishing the sexes. Another table gives the same occupations in classified instead of alphabetical order, distinguishing the ages to still greater minuteness, and also distinguishing the sexes. Another table, going as low down in classification as sub-classes, shows in respect to these the ratio or percentage of males under 20, males over 20, females under 20, and females over 20: this is done with a view of exhibiting, in a broad and general way, the extent of female labour and of juvenile labour in Great Britain. Lastly, a fourth table, or rather group of tables, gives the occupations of the people in all the 13 divisions of Great Britain, in all the counties, in all the 694 Registration Districts, and in 89 of the principal towns.

We proceed now to give some idea of the nature of the classification adopted.

The primary division, it must be understood, is into 17 groups or classes of persons having definite occupations, and these are again divided into 91 sub-classes, rather more than five to a class on an average. Thus:

I. Persons engaged in the general or local government of the country.
   1. National government.
   2. Local government.
   3. East India government.
II. Persons engaged in the defence of the country.
   1. Army.
III. Persons in the learned professions.
lodging, entertaining, attending, or providing articles of dress, so as to be brought much into personal contact with those whom they serve." This reads well, in so far as it provides a chain of connection among employments which relate especially to the person; but the sub-classes are in some degree unsatisfactory for the same reason; they expect inn-keepers, coffee-house keepers, eating-house keepers, lodging-house keepers, domestic servants, inn-servants, undertakers, dress-makers, shoe-makers, umbrella-makers, rag-gatherers, and washer-women, to be all included in one class, as they are in the schedules: class 4 consists of "the poet, the historian, the painter, the sculptor, the musician, the architect, and the natural philosopher, as well as the professors and teachers of literature and science"; while class 11 comprises those engaged in the higher class of mechanical and chemical arts; they are intimately connected with artists and men of science, from whom they frequently, either directly or indirectly, derive materials, direction, or inspiration; they multiply copies of original works." Now this analysis has evidently been much studied and elaborated by the commissioners; but it leads to strange results when worked out in detail; for we find the music-master in one class and the musician in another, the painter in one and the engraver in another, the architect in one and the surveyor in another, the printer in one and the painter in another, the engraver in one and the manufacturer in another, the carpenter in one and the cabinet-maker in another, and the chemist in one and the chemical manufacturer in another. All are thrown together in one class. The showman, the civil engineer, the publisher, the dyer—here is an odd group! Taking the 1057 occupations for males, just as they stand in the classified tables, the highest numbers are the following, comparing those exceeding 40,000 persons in each employment:

1. Agricultural labourers
2. Labourers (unskilled)
3. Farmers
4. Shepherds
5. Farm servants, indoor
6. Cotton spinners and weavers
7. Coal miners
8. Carpenters
9. Tanners
10. Blacksmiths
11. Masons
12. Porters and messengers
13. Merchant seamen
14. Woolen spinners and weavers
15. Domestic servants
16. Gardeners
17. Grocers
18. Butchers
19. Plumbers, painters, and glaziers
20. Cabin drivers
21. Bakers
22. Silk spinners and weavers
23. Engineers and machinists
24. Silk spinners and weavers
25. Clerks (commercial)

Among females, of 20 years of age and upwards, the highest numbers placed opposite definite occupations are the following:

1. Domestic servants (general)
2. Milliners
3. bbcq
4. Washermen and washwomen
5. Farm servants, in-door

These numbers, however, must not be used for any inferences, without taking others belonging to establishments collaboratively connected with them. Thus, the 401,930 general servants do not include about 200,000 others who enter themselves under the more specific designations of housekeeper, household, cook, nurse, and inn servant; the 205,477 milliners do not include the 143,212 who do not come under this class, and the 136,562 who wash women and combing and the 67,538 who are out-door servants. We find

Wives (not otherwise specified)
Children and relations at home, ditto
Children who attend school, ditto

The above must be remembered, as the 91 sub-class of males. The sub-class of females occupations are not quite so numerous, and differ a little (but a little) in designation.

The 17 classes, or 91 sub-classes are further subdivided into no less than 1057 occupations or employments, giving an average of about twelve to each sub-class, or sixty-two to each class. These are occupations for males only; but there is a separate classification for females amounting to 746 employments. These are, of course, in some cases identical with those of men, in other cases nearly alike but differently named, while in others they are wholly distinct and female in their character.

Many of the classes cannot be rightly understood until the sub-classes into which they are divided have been examined; and even then, there are two or three against which grave doubts might be urged, as to the principle wherein the aggregation has been made. The classes and 11 are those here adverted to. This, however, is a matter on which opinions will inevitably clash; for, where offices or employments differ from one another by imperceptible gradations, and where each one may be regarded under many aspects, no one can determine which is the classification: we can only adopt a classification, convenient according to the views of him who makes it. The commissioners, for instance, made class 6 to comprise "people who are principally engaged in

10. In arms.

The above, it must be remembered, are the 91 sub-classes of male occupations. The sub-classes of female occupations are not quite so numerous, and differ a little (but a little) in designation.

The 17 classes, or 91 sub-classes are further subdivided into no less than 1057 occupations or employments, giving an average of about twelve to each sub-class, or sixty-two to each class. These are occupations for males only; but there is a separate classification for females amounting to 746 employments. The commissioners, for instance, made class 6 to comprise "people who are principally engaged in
Here we have at once more than a third of the entire population entered under three headings, excluding everything like a business designation.

As a summary of results relating generally, without regard to age, sex, or topographical distribution, it may be given to give some idea of the manufacturing capacity, containing the Commissioners' own enumeration of the number of persons employed in 108 avocations in Great Britain, comprising all those for or in regard to which the numbers exceeded 10,000: mere domestic relationship, such as 'wife,' 'widow,' &c. is not taken into account, as is the usual meaning of that word—male or female adult or juvenile.

**1145 masters each employ 100 men or upwards:**

It is in Lancashire chiefly that the factories are situated in which the largest number of persons are employed. This might be expected, knowing, as we do, how on gigantic scale the cotton-mills of that county are conducted. Not less than 106 of the Lancashire mills employ more than 350 hands each; how much more, here, is not stated in detail. There are also 10 engineers or machine masters, each of whom has at least 350 workpeople.

In London the number of workpeople employed by the respective masters differs, of course, from that observable in country lists. In the large conurbations, for instance, Taking 100 as a minimum, it may be asked,—Which are the London trades comprising the greatest number of masters who employ 100 men or more each? We find that there are altogether 68 of such masters—a smaller number than might at first perhaps have been supposed. Of these, there are 22 builders, 6 engineers, 5 shoemakers, 5 printers, 4 painters and glaziers, 3 pianoforte manufacturers, 9 each of bookbinders, gunsmiths, masons, tanners, silk manufacturers, drapers, tobacconists, confectioners, silversmiths, iron-manufacturers, mineral-workers, and 1 each of hatters, tailors, omnibus-proprietors, coach-makers, carpenters, dyers, brewers, sugar-refiners, cooperers, brickmakers, gas-fitters, and cutlers, and a few are very questionable. For instance, among shipbuilders in the metropolis, there is not one entered with so many as 50 men in his employ; among distillers and recifiers, not one with so many as 20; evidently there are great omissions here. Again, when we find that there are only 6 vinegar makers, 9 dye manufacturers, 1 law-stationer, entered as employing any persons at all, it is still more manifest that many of these returns were incomplete. The explanation is doubtless to be found in the statement prefixed to the Table: "Many employers of the increasing number of small tradesmen directed attention, are sufficient to show that great caution is necessary in drawing deductions, as in some cases they would certainly be by no means just ones.

The small establishments in the metropolis, are, in many respects, the most important of all, on account of their large number. The small chamber-masters, or small shopkeepers who employ each not more than two journeymen, or two apprentices, or one journeyman and one apprentice, are surprisingly numerous, showing to how great a degree master-
ship is diffused in the metropolis. We give the following table of chief trades followed by Masters who employ 1 or not more than 2 Journeymen or Apprentices.

<table>

</tr>
</tbody>
</table>

The table is to be understood thus: that in the above eight occupations there are 3183 masters in the metropolis, who employ either one or two persons each. Of those, still lower in the social scale, who claim mastership only over their own individual labour, the numbers run in a somewhat different order, beginning with a shoemaker (the 'cobbler who lives in a stall,' perhaps), and going thence to the tailor, the butcher, the baker, the grocer, the carpenter. But these numbers include also those masters who made no definite returns at all.

In respect of agricultural pursuits, the Commissioners sought to obtain a return of the number of farms, the size of the farms, and the number of persons engaged in them. The following is a convenient general outline of the result:

<table>
<thead>
<tr>
<th>Size of Farms</th>
<th>Number of Farms</th>

</tbody>
</table>

and upwards.

Besides the above, there were 2658 farms of which the sizes were not stated in the returns; making 285,936 farms or farm-holdings altogether. It is found that large farms prevail most in the North, and in Norfolk and Suffolk. The average size of all the farms is 102 acres; and, taken in the aggregate, they occupy just about one-half of the territory of Great Britain. Two-thirds of the farms are less than 100 acres each in extent. About 9000 small farmers seem to have no labourers except the members of their own families; about 170 farmers employ more than 600 each, while all the rest have in their service a number varying from 1 to 60.

Professional avocations, as distinguished from trading and manufacturing pursuits, present a few interesting facts, which may be put together in the following form:

**Persons engaged in the government of the country—**
- **Civil service**
  - Males: 30,849
  - Females: 1,487
- **Local service**
  - Males: 22,051
  - Females: 1,113
- **East India (in England)**
  - Males: 3,774

**Persons engaged in the defence of the country—**
- **Army:**
  - Males: 70,718
  - Females: 26,796

**Persons engaged in religious duties—**
- **Clergymen of national churches**
  - Males: 16,567
  - Females: 2,411
- **Other ministers**
  - Males: 6,614
- **Subordinate officers**
  - Males: 6,671

**Persons engaged in law and justice—**
- **Judges**
  - Males: 85
- **Baristers, advocates, &c.**
  - Males: 3,111
- **Solicitors, attorneys, &c.**
  - Males: 13,582
- **Law agents**
  - Males: 1,659
- **Law clerks, &c.**
  - Males: 19,149

**Persons engaged in the medical profession—**
- **Physicians**
  - Males: 2,928
- **Surgeons and apothecaries**
  - Males: 15,163
- **Chemists and druggists**
  - Males: 15,333
- **Students and assistants**
  - Males: 3,655
  - Females: 2,012

**Miscellaneous**
- Males: 571

*But the total of the Queen’s forces, at home and abroad, naval and military, including non-commissioned officers, was 228,078.*

It is necessary to bear in mind that many dissecting museums are in the Census returns, entered under the occupations which they follow during the week.

Persons engaged in literature, the fine arts, and sciences—
- **Males:**
  - Writers, editors, &c.: 3,249
  - Artists, architects, &c.: 6,609
  - Scientific persons: 496
- **Females:**
  - Professors and teachers: 8,410

As before noticed, there is more confusion between Class 4 and Class 11. In the list here given, although artists are included in Class 11, it must not be inferred that they are, but not singers; dramatists are, but not actors. In order, therefore, to make our enumeration somewhat more complete, we must bring in a few items from Class 11, still comprising them among persons engaged in literature, fine arts, and sciences.

**Actors and actresses, theatre servants—**
- Males: 1,485
- Females: 798

**Engravers—**
- Males: 5,507

**Model makers and modellers—**
- Males: 2,263

**Pattern designers—**
- Males: 707

**Draughtsmen—**
- Males: 1,016

**Medallists and die-sinkers—**
- Males: 489

**Supposing that the above may be fairly reckoned as professional employments, it appears that on Census-day in 1861, there were 344,464 males and 78,467 females thus occupied. These comprise 1 in 30 of all the males, 1 in 140 of all the females, and 1 in 50 of the whole population. If we omit the sailors and soldiers from the list of professional men, the fraction becomes 1 in 120.

Perhaps it will ultimately be found that the most valuable tables in the Census Reports are those which establish a comparison between different parts of the country. Large generalizations could not be made from the tables which relate to the whole of Great Britain; but for comparison and extension the sectional tables will have a peculiar value of their own. In reference to a particular department of occupation, or a particular social relation, we may wish to know how far Wales differs from England, and Scotland from England; but far the 10 Divisions into which England is separated differ one from another in characteristics; in what way the 40 English Counties, 12 Welsh Counties, and 32 Scotch Counties exhibit peculiar characteristics; by what peculiarities the 692 registration districts or poor-law unions of England and Wales are distinguished; and so forth. The voluminous Census tables afford a store of information on all these local details.

Of course, when different districts or portions of the kingdom are treated separately, the metropolis comes in for the first notice; the following, then, is a rough outline of employment generally in the metropolis. Confining our attention, at present, to males, and to males only of 20 years and upwards, we find the following facts: That out of the 5,490,815 males of 20 years and upwards in Great Britain, 632,945 live in the metropolis; that the London shoemakers number 26,689, and the London tailors, 30,527; that there are no fewer than 25,706 domestic and inn servants; that the commercial establishments are so numerous and important as to employ 15,133 clerks and travellers; that the coachmen, drivers, carriers, waggoners, draymen, and others who drive vehicles through the London streets, number more than 17,000, besides 14,000 messengers and porters, in addition to railway, canal, and river servants; that there are, for housework, 21,174 carpenters, 13,917 painters and glaziers, and 16,038 bricklayers and plasterers; that among those who supply us with food and drink, there are 9,941 bakers, 7,428 butchers, 4,456 grocers, 6,474 furnishers, and 10,623 millers and millers; that out of 5,490,815 males of 20 years and upwards in Great Britain, 767,418 are in London. Of this number, 316,157 designate themselves simply as wives; and 36,627 simply as widows, and about 40,000 as daughters, without any dependence, but who do not appear to earn their living by the labour of their own hands or brains, there are no fewer than 116,855 domestic servants of various
kinds, 73,620 needlewomen of various kinds, and 45,754 charwomen, washerwomen, and manglers. These, with 37,600 women employed in domestic service, comprise all the large items among the female adult population of the metropolis; all the other items are, individually, very small. These facts are not without their instruction; for the principle is the range of female employment in London. They indicate, among those who are dependent on relations for support, and those of independent means, there were 330,000 adult females in London in 1651 dependent on their own exertions for their daily bread. It is also well to remember the number of families in comfortable circumstances in London, to give employment to nearly 120,000 female servants, and 45,000 laundry- and char-women.

But now let us compare one of the manufacturing counties of Northumberland with Lancashire, and see how far a similar principle seems to determine the distribution of occupations. We take the cotton-spinning county of Lancashire. Here we have 530,075 males of 20 years of age or upwards, against 632,465 in the metropolis; that is, in the ratio of about 65 to 100. Different indeed, however, is the ratio in regard to employments. We have seen that the metropolis contains about 28,000 male adult servants, 31,000 drivers and porters, 27,000 shoemakers, 21,000 carpenters, 20,000 tailors, 18,000 bakers, 15,000 tailors, 11,000 victuallers, and 8,000 in Lancashire, these eight occupations exhibit the numbers, 4708, 9127, 15,443, 15,146, 11,346, 7658, 7643, 6336— all far below the ratio in respect to total inhabitants. In London there are 35,000 persons in the public service, receiving contributions from the community large in number, in Lancashire there are only 11,000. In London there are 34,000 professional men, engaged in divinity, law, physic, science, and fine arts; in Lancashire the number is 11,000. In London there are 14,000 persons employed in writing, printing, binding, and selling books and periodicals; in Lancashire there are 2,000. All these numbers, it is evident at a glance, differ widely; London having far more than its ratio of 100 to 65 in each of these employments. But let us extend our inquiry into the trades in Lancashire and see what is the proportion. Lancashire takes precedence of the metropolis. Of course, in a county, farmers, graziers, shepherds, gardeners, agricultural labourers, and so forth, must be relatively more numerous than in a city; and thus we need not be surprised to find 56,000 of these in the metropolis, against 14,000 in the metropolis. And, considering the wonderful shipping activity of Liverpool, and the numerous canals which traverse Lancashire in every direction, we may be prepared to expect the merchants to do no more than 6,000 of the men in the numbers of persons connected with ships, boats, and barges in various capacities; in the metropolis, this number is about 31,000, in Lancashire 18,000—very nearly, indeed, in the ratio of 100 to 65. But it is in textile manufactures, and in cotton manufactures in particular, that most of the men in Lancashire are employed, and which lead before London. In Lancashire there are 104,000 persons (out of about 540,000) engaged in various departments of the cotton manufacture, against a few hundreds in London; 7000 in woolen manufactures, against a few hundreds; 21,000 coal miners and labourers, against 5000; 3000 quanrymen, against 500.

Here it must be borne in mind, that the numbers in the preceding paragraph are of males only, and males too who have reached their 20th year or upwards. A few parallel entries will suffice, relating to certain occupations for adult females: of domestic servants and nurses there are 122,000 in London, and 55,000 in Lancashire; of silk-workers, 8000 in London, and 21,000 in Lancashire; of tailors, 10000 in London, and 9000 in Lancashire. Here we find that one-sixth of all the adult females in London are domestic servants or nurses, and that one-sixth of all the adult females in Lancashire are engaged in the cotton manufacture. There are also striking differences in respect to juvenile labour:—the metropolis contains 474,013 males, and 493,260 females, under 20 years of age; the numbers in Lancashire are 465,749 and 478,046. Now in the metropolis, after deducting 770,000 young persons who are employed only in their domestic or family relations, without connection with any particular employment, there remain about 200,000 who are considered to have some occupation or other; while in Lancashire, of the 770,000, and out of this number about 120,000 are employed in the cotton manufacture alone—that is, 120,000 young persons.

In the metropolis, on the other hand, young seamstresses and young domestic servants chiefly fill the list.

We turn now to other phases of metropolitan employment. Of the whole 2,362,226 inhabitants, there are, in round numbers, 630,000 men, 760,000 women, and 970,000 persons of both sexes under 20 years of age. Of this latter number, nearly 300,000 are under 5 years of age, and therefore almost equally distributed between sex. In order to show, then, how far male employments are to be met with in London for young persons, we give the following table in relation to a few occupations:—

<table>
<thead>
<tr>
<th>Occupation</th>
<th>Under 20, 20 and upwards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Teachers</td>
<td>1,280</td>
</tr>
<tr>
<td>Messengers and porters</td>
<td>19,748</td>
</tr>
<tr>
<td>Printers, &amp;c</td>
<td>3,218</td>
</tr>
<tr>
<td>Silk manufacturers</td>
<td>3,896</td>
</tr>
<tr>
<td>Cabinet-makers</td>
<td>2,561</td>
</tr>
<tr>
<td>Gold and silver work</td>
<td>1,145</td>
</tr>
<tr>
<td>Brass work</td>
<td>1,068</td>
</tr>
<tr>
<td>Building trades</td>
<td>5,951</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Under 20, 20 and upwards</td>
</tr>
<tr>
<td>Teachers</td>
<td>1,514</td>
</tr>
<tr>
<td>Servants</td>
<td>46,324</td>
</tr>
<tr>
<td>Needlewomen</td>
<td>9,184</td>
</tr>
<tr>
<td>Silk-workers</td>
<td>2,375</td>
</tr>
<tr>
<td>Paper-workers</td>
<td>625</td>
</tr>
</tbody>
</table>

It is probable that the greater part of the above young persons are apprentices, although the returns do not specify this fact in words. The 19,743 young messengers and porters are evidently the "errand boys," rather a formidable body in London. Taking female occupations instead of male, and noticing the difference of age in a similar manner, we find the following:—

<table>
<thead>
<tr>
<th>Occupation</th>
<th>Under 20, 20 and upwards</th>
</tr>
</thead>
<tbody>
<tr>
<td>Teachers</td>
<td>1,514</td>
</tr>
<tr>
<td>Servants</td>
<td>46,324</td>
</tr>
<tr>
<td>Needlewomen</td>
<td>9,184</td>
</tr>
<tr>
<td>Silk-workers</td>
<td>2,375</td>
</tr>
<tr>
<td>Paper-workers</td>
<td>625</td>
</tr>
</tbody>
</table>

If we were to name the three most characteristic kinds of occupations in London for males under 20 years of age, therefore, they would be apprentices to mechanical trades, errand boys, and small shopkeepers. As for females under 18 years of age, they would be servants, needlewomen, and teachers.

The 36 districts of London exhibit many remarkable groupings in reference to employments. It is well known that the members of a particular trade are wont, in many cases, to congregate near each other; but the Census tables show this more exactly. Lawyers live in Kennington district in greater relative numbers than in any other district—a fact for which there was no reason to expect; except those who live about Chancery-lane and the inns of court, are found in greater relative numbers at Islington. The authors, editors, artists, and architects, are found in small number south of the Thames, or in the eastern half of the metropolis; Marylebone, St. Pancras, and Kentish Town are their chief districts. Domestic servants are found in greatest relative force in the districts of St. George's Hanover Square, St. James's Westminster, Marylebone, and Kensington—indeed overwhelmingly so. The tailors are strong in St. James's, Marylebone, and St. Pancras, but relatively more so in the Whitechapel and neighbouring districts, where much of the slop work is done. The chief districts for shoemakers are St. Pancras and Marylebone in the north, Lambeth and Newington in the south, Whitechapel and Bethnal Green in the east. The gardeners have Kensington and Wandsworth as their chief districts. Beyond all other districts, the City is the locality for publishers and booksellers, for it contains the region most frequented by booksellers, and most of the courts around Fleet Street. Musical instrument makers congregate in decided preponderance in St. Pancras. There are two districts in which watchmakers appear in surprising force; these are, as may be supposed, Clerkenwell and St. Luke's. Coachmakers in Pancras and Marylebone; shipbuilders in Poplar; dyers and calenders in Shoreditch and Bethnal Green (where the silk manufacture is carried on); leather workers in Bermondsey (nearly as many as in all the other 25 districts combined); sugar refiners nearly all in Stepney, Whitechapel, and St. George's in the East; cabinet and furniture makers, Pancras, and especially Shoreditch; cooperers, in the districts nearest the various docks; rope and sail makers, Stepney and Bethnal Green; workers in gold, silver, and precious stones, Clerkenwell; all these is the chief associations between occupations and districts.

And so, in like manner, there are certain occupations for
adult females, which seem to be carried on in some districts rather than others. Domestic servants and governesses are, relatively to population, most numerous in the districts of Kensington, Marylebone, and St. George's Hanover Square; while schoolmistresses, as distinguished from governesses, are relatively as numerous in other districts. The charwomen are scattered in all the districts. Those engaged in the hat manufacture, binding, and so forth, are in Southwark and Bermondsey, where most of the hat factories are situated. The women tailors, who make waistcoats and cheap goods for the slop shops, are chiefly in the three eastern districts. The tailors at Whitechapel, and St. George's in the East. The milliners, as distinguished from seamstresses, are in greatest number in Marylebone and Pancras; but the seamstresses, who are understood to occupy a lower grade among needlewomen, are in strongest force in Stepney and St. George's in the East. Stickmakers are in Marylebone chiefly. The washerwomen and mantlers take up their abode chiefly in the genteel districts. The women who work at shoemaking live principally in Shoreditch and Bethnal Green; while the umbrella makers are more generally to be found in Whitechapel and St. George's in the East. The hawkers and pedlars are chiefly in the four districts just named. Artificial flower-makers in St. Pancras; silk workers in Bethnal Green; upholstery workers in Marylebone; lace workers in the same district—these are other examples of predominance.

For reasons already sufficiently indicated, it will be impossible to give abstracts of the county and district tables here; so much time is lost, and the classification carried. But we may be able to select a few examples sufficient to illustrate broad general principles of industrial distribution. For instance, every one knows that certain towns have become celebrated for certain manufactures; Sheffield for cutlery, Birmingham for small metal works, Manchester for cotton, Leicester and Nottingham for hosier, Leeds for woollens, Bradford for stuffs, and so on; but it may be useful and instructive to know more exactly the extent to which this localisation is carried. Again, there may be certain districts containing no very large towns, but in which some particular manufacture is nevertheless carried on to a remarkable extent; such as straw-plain, pillow-lace, needles, and many others.

Passing in review the principal cities, boroughs, and towns, we can readily determine from the tables, even without the aid of any previous knowledge on the subject, the prevailing character of the industry in each town, and to some extent the degree in which female labour and juvenile labour are made use of. Let us take a few of the towns in succession.

Birmingham. —Here the males under 20 years of age are 18,640, and above 20 years 61,276; the females under 20 years of age are 18,380, and above 20 years 61,326; or placing the numbers in a compact table, we have the result thus:

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>52,640</td>
<td>53,380</td>
<td>105,020 under 20 years</td>
</tr>
<tr>
<td>61,276</td>
<td>63,345</td>
<td>124,621 20 and upwards.</td>
</tr>
</tbody>
</table>

119,916 + 118,925 = 238,841 total population.

Now in respect to their population, we find that out of the various classes of occupations, classes 11 and 14 are those in which the Birmingham inhabitants are chiefly employed—viz., working in metal works. 2000 men making guns, 1800 making machines and tools, 2400 working in gold and silver, 3000 brass founders, 1400 button makers, 1200 white and blacksmiths, 1400 iron and 4000 nail makers. These are among the men of 20 years and upwards, but of the males under this age there are no less than 7000 employed in the few metal trades above enumerated. In Birmingham, females are largely employed in the smaller kind of metal manufactures; for example—1,300 young females and 1,600 adult females in making buttons; 700 and 1,100 in miscellaneous works in mixed metal; 800 and 1,900 in milliners, iron and steel works.

Manchester and Salford. —These cotton towns are

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>86,551</td>
<td>89,043</td>
<td>175,594 under 20 years</td>
</tr>
<tr>
<td>104,506 + 120,817</td>
<td>225,327 20 and upwards.</td>
<td></td>
</tr>
</tbody>
</table>

191,457 + 208,864 = 400,321 total population.

These are within the Parliamentary limits, which exceed the municipal. Now passing over the tailors and shoe-makers, the carpenters and painters, the bakers and butchers, who in all other towns may generally form a considerable part of the population, we turn to class 13 as likely to exhibit remarkable characteristics of the workers in Manchester and Salford. Here one single entry, cotton manufacture, comprises employed in all 18,500 men, 8,600 women, 14,503 women, 9,051 girls, making a total of 42,603, in which the females exceed the males by 23,654 against 18,949. Putting the whole of the textile manufactures together—relating to cotton, flax, silk, and wool, they appear to employ about 32,000 men, 20,000 boys, 20,000 women, and 12,000 girls, exhibiting the remarkably near equality of 33,000 males to 32,000 females—more than 1 in 7 of the entire population of Manchester and Salford employed in making the textile manufactures. Here, besides 12,000 tailors and seamstresses employed in making up textile manufactures, we fall in upon a paragraph, for brevity, applied the terms boys and girls to young persons under 20 years of age; and shall do so in those which follow.

Nottingham. —Here we enter a bobbin-net and cotton stocking town.

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>11,782 + 12,745</td>
<td>24,528 under 20 years</td>
<td></td>
</tr>
<tr>
<td>14,805 + 18,074</td>
<td>32,879 20 and upwards.</td>
<td></td>
</tr>
</tbody>
</table>

26,587 + 30,829 = 57,407 total population.

Of course the numbers in any particular occupation here will appear much smaller than in Manchester, because the population is only one-seventh as large; but the following entries are well worthy of note: stocking-makers, 2,459 men, 500 boys, 1,879 women, 634 girls, making nearly 6,000 persons, or more than one-twelfth of the whole of the inhabitants employed, employed in this one branch alone. The bobbin-net manufacture employs 1,576 men, 517 boys, 3,277 women, 1,802 girls, exhibiting a still more striking total of more than 7,000 persons. Of the aggregate 12,000, more than 7,000 are females. It is worthy of notice that the hosiery and lace workers bear a larger ratio to the population of Nottingham, than the whole of the textile workers bear to the population of Manchester.

Methyr Tydfil. —We quit hosiery and lace, to turn to iron and coal—

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>14,357 + 13,629</td>
<td>27,985 under 20 years</td>
<td></td>
</tr>
<tr>
<td>19,590 + 15,443</td>
<td>35,033 20 and upwards.</td>
<td></td>
</tr>
</tbody>
</table>

34,007 + 29,071 = 63,078 total population.

Now in this remarkable town we glance over the classes of occupation, one after another, without meeting with any numbers so large as to arrest the attention. At last, however, in class 14, we encounter them in surprising force. There are 2,000 persons engaged 'coal-miners, 4,302 men; and among iron workers are 2,038 boys and 6,615 men; making a total of about 15,000 workers in these two minerals alone; these, with 700 or 800 females similarly employed, comprise a quarter of the entire population. Considerably more than half the male population of Methyr Tydfil are workers in iron and coal, employed chiefly in the great establishments of Dowlais, Cyfarthfa, Pen-y-darren, and Plymouth works.

Bradford. —This busy Yorkshire town introduces us to a wholly different class of manufactures. The parliamentary borough is somewhat extensive, and includes some of the neighbouring villages, comprising a population of—

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>22,934 + 24,899</td>
<td>47,833 under 20 years</td>
<td></td>
</tr>
<tr>
<td>27,932 + 20,413</td>
<td>48,445 20 and upwards.</td>
<td></td>
</tr>
</tbody>
</table>

49,966 + 53,912 = 103,778 total population.

After making allowance for the large number of tailors, shoemakers, carpenters, masons, and similar handicraftsmen for supplying the wants of so large a population, we find that class 15 contains the employments characteristic of Bradford. Here we entered, under weaving, 18,000 male manufacture, 5381 boys, 10,759 men, 7936 girls, and 8780 women—a powerful body of about 33,000 persons (nearly a third of the whole population) employed in worsted and stuff manufactures; also in woollen cloth, the silk, and the cotton manufactures, occupy perhaps 1000 altogether, showing how insignificant they are at Bradford.
Leeds.—The borough contains—

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>36,468</td>
<td>38,587</td>
<td>75,055</td>
</tr>
<tr>
<td>43,546</td>
<td>48,589</td>
<td>92,135</td>
</tr>
<tr>
<td>83,714</td>
<td>88,176</td>
<td>171,890 total population.</td>
</tr>
</tbody>
</table>

We devote a short paragraph to Leeds, for the purpose of showing how remarkable a contrast may be presented in the industry of two towns situated only about ten miles apart. Bradford and Leeds both work up wool largely; but Bradford prepares it for stuff or worsted fabrics, while Leeds prepares it for woolen cloth. Leeds has 29,280 boys, 7,640 men, 1,710 girls, and 2,284 women employed in making woolen cloth: while the stuff and worsted manufacturers here employ 1,000. Leeds also has over 1,000 large manufacturing towns in other respects; for it employs about 9,000 persons in the flax manufacture, and 3,000 in making engines and machines. Relatively to the population, Huddersfield is perhaps more peculiarly associated with Leeds than with the woolen cloth manufacture.

Macclesfield.—Having given a idea of the distribution of occupations in the towns which may be regarded as the chief seats of the cotton, woolen, and stuff manufactures, let us do the same in reference to the silk-workers of Macclesfield borough—

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>8,299</td>
<td>8,735</td>
<td>17,034 under 20 years.</td>
</tr>
<tr>
<td>10,542</td>
<td>11,772</td>
<td>22,914 20 and upwards.</td>
</tr>
<tr>
<td>18,541</td>
<td>20,607</td>
<td>38,048 total population.</td>
</tr>
</tbody>
</table>

There are 2462 boys, 4,772 men, 2,979 girls, and 4,330 women employed in the silk manufacture, making an aggregate of about 14,500 persons, considerably more than one-third of the entire population. The males and females are employed in almost exactly equal numbers, 7,354 to 7,318.

Sheffield.—In this cutlery borough there are—

<table>
<thead>
<tr>
<th>Males</th>
<th>Females</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>5,028</td>
<td>5,270</td>
<td>10,298 under 20 years.</td>
</tr>
<tr>
<td>36,392</td>
<td>35,698</td>
<td>72,090 20 and upwards.</td>
</tr>
<tr>
<td>67,390</td>
<td>67,310</td>
<td>134,700 total population.</td>
</tr>
</tbody>
</table>

In the classes relating to the supply of food, clothing, and dwellings, Sheffield contains a number fairly proportionate to its population; but it is only in class 14 that the industrial characteristics make their appearance. The works in gold, silver, steel, iron, and mixed metals employ about 20,000 men and boys at Sheffield. Females are very little employed in the metal trades, thereby presenting a striking contrast to the circumstances at Birmingham. No fewer than 2,461 boys and 7,044 men are employed in making and grinding cutlery and files alone.

Glasgow.—There are two or three Scotch towns which present remarkable characteristics. Glasgow—

<table>

</tr>
<tr>
<td>154,929</td>
<td>174,167</td>
<td>329,096 total population.</td>
</tr>
</tbody>
</table>

This busy city is worth of note for the degree in which it combines cotton working and iron working, two departments of industry which certainly do not seem to have any necessary bond of connection. There are 3449 boys, 11,571 men, 9,629 girls, and 14,442 women—about 15,000 men and 26,000 females—employed in various branches of the cotton manufacture. Of all the females in Glasgow, in every age and condition, one in seven are employed in this manufacture. There are, in respect to metal trades, 2600 machine and tool makers, 4000 miners and manufacturers, and 5400 other workers in metal—almost wholly females.

Dundee.—This is the great centre of the flax and linen manufacture of Scotland. Dundee contains—

Of these numbers there are 2713 boys, 6161 men, 4300 girls, and 6565 women employed in flax and linen manufactures, being almost exactly one-fourth of the whole population—a ratio which certainly appears surprisingly large. Aberdeen is also engaged in these trades, but in a very much smaller ratio than Dundee.

These few examples would perhaps suffice to illustrate the distribution of particular branches of manufacture in the principal towns; but, adopting a still more compressed form, we will give a few additional instances in the following way—

At Portsmouth, out of about 35,000 men and boys in the borough, about 9000 are in the public service, and receive pay from the community; while there are about 2000 private persons employed as seamen or as shipwrights. At Leicester, out of 60,000 inhabitants, 10,900 are engaged in Worstings, stockings, and similar articles. At Northampton, out of 13,000 men and boys, more than 4000 are employed in making boots and shoes, the staple industry of the place; and at Stafford, 10,000 boys and 1700 men are making worsted stockings, and the ratio of one to four of the whole male population. At Worcester, out of 16,000 women and girls, 2133 are employed in making gloves. Of the 25,705 men and boys in Wolverhampton, about 7600 are employed upon metals or upon coal; no less than 1400 make locks alone. In Dudley the ratio is as high, about 6000 out of 19,093. Coventry is remarkable for two trades, about as diverse as any two can be, ribbon-making and watch-making: out of a population of 36,612, nearly 10,000 persons, of whom 6500 are females and 3500 are silks and ribbons: while 1700 men and boys are making watches. At Stockport, 17,000 persons are employed in cotton manufactures, out of a total population of 53,385—nearly one in three; at Blackburn, 6,000 out of 32,000 inhabitants, or more than one in five; at Bolton, 14,500 out of 61,171; at Oldham, 20,000 out of 72,307; at Preston, 18,000 out of 69,542. Thus, in these five cotton spinning and weaving towns, containing an aggregate of about 300,000 inhabitants, about 34,000 males and 42,000 females—considerably more than one-fourth of all the inhabitants—are engaged in this manufacture. Looking at the distribution of workers in reference to age, we find that there are about 33,000 children and young persons under 20, and 43,000 adults and elderly persons out of 31,000 inhabitants, nearly 9000 are employed in various kinds of textile manufacture, of which the principal is shawls.

Hitherto, in the above paragraphs, we have spoken of distinct towns, each with defined limits and defined number of inhabitants. But a few remarkable manufactures are centred rather in districts than in large towns.

In Staffordshire, the registration county which often differs slightly from the parliamentary county (being the real county), contains 320,903 males and 309,641 females. Now it is plain, on a little examination, that the main departments of industry whereby these are supported have relation to mineral manufactures; and it is further observable, on comparing the several districts, that while the southern exhibit the metallic and colliery operations, the northern are associated with earthenware manufactures. In short, we have the Wolverhampton region of the south, and the pottery region of the north. There are 27,000 males and 10,000 females in pottery and earthenware manufactures. It is worthy of note that in the two districts or Poor Law Unions of Stoke-upon-Trent and Wedleston, containing the pottery towns of Stoke, Hanley, Lane End, Delph, Etruria, Shelton, Burslem, &c., out of a population of 51,000 adult males and females, more than 13,000 are engaged in the earthenware manufacture. And it is to be observed that the district of South Staffordshire, it would perhaps scarcely be expected that 6000 women are engaged in nail-making.

Berkshire, containing 62,533 males and 67,966 females, is not a county likely to contain large manufacturing establishments of any kind; but there are, nevertheless, two or three entries in the tables which deserve attention. There are, we find, 5200 men and more than 10,000 females engaged in the straw-plait manufacture; together with nearly 6000 females employed in lace and lace-making. One fourth of all the females in the county, of all ages and conditions, are employed in one or other of these two occupations. In Buckinghamshire, containing 70,938 males and 72,747 females, the straw-plait trade is smaller, employing only 2000 females; but the lace-trade is about as extensive as in Bedfordshire, employing nearly 11,000 females. In Hertford-
OCC 470 OCO

We almost entirely lose the lace-trade; but the straw-plait employs about 9000 females out of 87,497. In Cambridge, these are about 500, and in Little Claire, only 10.

Cornwall is rich in metals, but has no coal. It has 172,193 males in the (registration) county. Among these are 3000 seamen and 2600 fishermen; but when we come to class the males employed in the busy trade, we find, 25,000 tin-miners, more than 10,000 tin-miners, 2500 lead-miners, and about 6000 employed in other ways on metals and minerals; none, however, in coal. There are also about 6000 females engaged at the 'above-ground' works of the copper and tin mines.

Let us contrast this with a county containing much coal but little metal. Durham (registration) county contains 207,068 males, and 204,981 females, a departure from the general rule; for here we find more males than females. Now the county contains both the busy trade and the hay trade; and the busy trade is not engaged in navigation; a very large number out of such a population, and evidently due principally to the navigation of colliery vessels. The number of 4600 ship and boat builders is also large, and the hay trade is an important one. But the much larger item is that of 29,000 men and boys employed in coal-mining and working, about one-seventh of the male population. In Northumberland, as might be expected, a somewhat parallel state of things presents itself. There are here 148,615 males, and of these, about 6000 are engaged in navigating ships and boats, 1400 in building ships and boats, and 11,000 coal-miners; the parallelism, it will be observed, is in the nature of the prevalent occupation, and not in the numbers. Farmers get great help in this respect. Five of the coal-miners of Northumberland seem entered as being upwards of 90 years of age; but it is satisfactory to find that, consequent on recent legislation, scarcely any boys under 10 years of age, or females of any age, are included among the coal-miners or labourers.

There are two counties in the western part of the kingdom which we may similarly notice, in respect partly to the iron manufacture, but still more decidedly to coal-mining. The counties of Montgomery and Glamorgan. Montgomery-shire contains 95,301 males, and 87,260 females. For example, in a mining county, of the males outnumbering the females. The iron trades occupy 12,000 males, and the coal trade also 12,000—in round numbers: together more than 24,000 males; but not much employed in these trades in this county. Glamorganshire, containing the remarkable towns of Merthyr and Aberdare and their vicinity, has a population of 125,057 males and 115,060 females. Of these males, no less a number than 16,500 are engaged in the coal trade, and 14,000 in the iron trades. In another Welsh county, Caermarthen, copper manufactures are in respect to the population, if not as remarkable as iron manufactures in Glamorganshire, at least worthy of note as the staple industry of portions of the country. The explanation of this is, that nearly all the copper ores of Cornwall and Devon are sold on the spot to copper-smellers, who have their works at Swansea or Neath, or at some similar place in Caermarthen-shire. But besides the copper workers there are, among the 125,057 males in this county, 14,000 workers in iron, and 16,000 coal-miners.

There are about 120,000 engaged in various departments of wool and worsted manufactures; and out of 673,159 females, about 90,000. In all the West Riding of Yorkshire, out of 606,918 males of all ages, there are about 120,000 engaged in various departments of wool and worsted manufactures; and out of 673,159 females, about 90,000. In all the West Riding of Yorkshire, out of 606,918 males of all ages, about 15,000 are under 20 years of age. In comparing the above numbers, we observe the following results:—that the male workers in wool bear a larger ratio to the whole male population in the West Riding, than the male workers in the worsted trade; and, in the worsted trade, that the female workers in Yorkshire are more numerous; and in a subservient capacity, about 1 in 6 of the West Riding population is engaged in the wool manufactures.

Such are a few of the most striking results obtained by the compilation of the returns of the registration and census for the year 1861. The year 1861 is the year of the census, and the returns are required to be furnished to the returns for the year 1861. The name is thus made to comprise the Andaman Islands, all the islands of the Indian Archipelago, Sumatra, Java, Borneo, Celebes, the Moluccas, the Philippines, Formosa, Australia and New Zealand. Only the inhabited groups of islands in the Pacific within the limits stated above are included in the islands of the mainland of the eastern world.

O'Connell, Daniel, the eldest son of Morgan O'Connell, was born at his father's residence, near Cahirciveen, Kerry, August 6, 1775. The family of Connell, or O'Connell, is of antiquity in the south of Ireland, but the circumstances of the father of Daniel O'Connell were much straitened. He was the third son of a gentleman farmer, according to his MSS., for he sent him at an early age to "poor old hedge-schoolmaster," named David Mahoney, who first taught the Irish agitator his letters. At the age of thirteen Daniel O'Connell was removed to a school at Redington, near Cove, county Cork, kept by the Rev. Mr. Harrington, a Roman Catholic priest: this school is said to have been the first publicly opened in Ireland after the repeal of the persecuting laws which made it penal for a Roman Catholic to educate his children. In 1790 Daniel, then a boy of 14 years, was sent to a school kept by a Mr. Anderson, with the design of being sent to L'Isle; but on reaching that place he was found to be too old for admission, and accordingly he was entered at St. Omer's. There he remained till 1792, when he was sent to St. Cadoc's at Anglesey. Female pupils were not admitted there, and Mr. O'Connell established the Benedictines at Douai. Returning after a few months to St. Omer's, he rose speedily to the head of the college; and so arrested the attention of the then president, Dr. Stappleton, that he prophesied that he would hereafter make a remarkable figure in the world. The first outbreak of the French revolution scattered the scholars of the Roman Catholic colleges at Douai and St. Omer's. Daniel O'Connell succeeded in reaching Calais safely and, and, having on board the English packet-boat, he landed on the shores of England, "half a Tory at heart"—so deep and keen was the impression left upon his mind by the excesses of the revolution in France.

The legal profession having been recently thrown open to members of his faith, in 1794 entered himself a student at Lincoln's Inn; and four years afterwards was called to the bar, having taken no ordinary pains to qualify himself. His first public speech was against the proposed union between the English and Irish legislatures. It was delivered on the 5th of May, 1796, before a meeting of the Society of Dublin lawyers at the Royal Exchange in that city, for the purpose of petitioning against that measure; but the meeting was broken up by the intervention of the military. In 1802 Mr. O'Connell, while attending a meeting of the Carlow numbers, in the society of Pembroke, was married privately to his cousin Mary, the daughter of Dr. O'Connell of Tralee. The calamitous occurrences however connected with the Irish outbreak of 1803, known by the name of Emmet's rebellion, found Mr. O'Connell already in possession of a moderate practice. He was not becoming gradually absorbed in the arena of political con-
tention. Emmett's trial was the starting point of a new era in the history of Irish agitation: the cruelty inflicted by the citizen-soldiers made an impression as deep and lasting as it was general, and the 'Catholic Question,' as it was called, rose daily in importance. From this time forward Mr. O'Connell took the leading part in the proceedings of the Roman Catholic claims. "For more than twenty years," he writes to the late Lord Shrewsbury, "before the passing of the Emancipation Bill, the burden of the cause was thrown upon me. I had to arrange the meetings, to prepare resolutions, to make the representations, to call the case of each person complaining of practical grievances, to reuse the torpido, to animate the lukewarm, to control the violent and inflammatory, to avoid the shoals and breakers of the law, to guard against multiplied treachery, and at all times to make personal and continuous sacrifices of the most formidable enemies of the cause." Day and night he devoted himself with surprising energy to the work, without receiving pay or fee. In 1804 the 'Catholic Board' was dissolved by a proclamation from Government, but it was immediately revived under the name of the 'Catholic Committee.' It met in the Exhibition House in William-street, and its debates were reported from January 1808.

In 1816 Mr. O'Connell fought his duel with Mr. d'Estrete, and divided his Dublin corporation; and the misfortunes of Ireland's present stage of politics and the misfortune of his own life, inflicted upon his adversary a wound which ultimately proved fatal: it is but just to add that for this result he ever afterwards felt and expressed the most painful remorse. Mr. O'Connell's public life henceforth offers very little material for comment. The only piece of news that is worth noting is the death of the Roman Catholic Emancipation Bill was carried. In the summer of 1828, when the fever and excitement on the subject then in suspense was at its height, Mr. O'Connell and his friends judged the time had come for referring the question to the consideration of the legislature. In the June of that year the vacancy occurred in the representation of Clare county, and Mr. O'Connell, though a Roman Catholic, was proposed as a candidate against Mr. (afterwards Lord) Fitzgerald. He was returned to sit for Clare in the House of Commons for Westminster for the purpose of taking his seat in St. Stephen's. As a Roman Catholic, he of course refused to take the oaths drawn expressly against the doctrines of the Roman Catholic Church. Discussions in the house, and arguments at the bar enlivened, and though the times remained without any practical result, yet the agitation in Ireland began to assume a formidable appearance, and to threaten another outbreak. Alarmed at the probable consequences of further opposition to claims which a large majority of educated minds think just and equitable, the Duke of Wellington and Sir Robert Peel gave way, and early in the following year brought into Parliament a bill for the repeal of the last civil disabilities under which the Roman Catholics of Ireland suffered. Mr. O'Connell was re-elected, and took his seat as member of Parliament in May 1829. In the following year, at the general election consequent upon the death of George IV., Mr. O'Connell exchanged the representation of Clare for that of his native county of Kerry. He represented Dublin from 1828 to June 1835, when he was unseated on petition, but was immediately afterwards returned for Kilkenny. In 1837 he was once more returned for Dublin, and in 1841 for the county of Cork. To carry on more effectively the agitation, Mr. O'Connell had relinquished his professional practice, and as a compensation for his loss of income, an annual subscription was organised, which afterwards came to be known as the 'Rent.'

The year 1841 witnessed the return of Sir R. Peel and the Conservative party to power, and this was the signal for renewed agitation in Ireland. In the following year, Mr. O'Connell commenced his movement in favour of a repeal of the Union, which met with general sympathy from the violent and the ignorant as throughout the rest of Ireland. The church of Ireland on Oct. 8th in the latter year, was forbidden by government authority, and a state prosecution for high treason was commenced against Mr. O'Connell and the other ringleaders. Mr. O'Connell was convicted of sedition, sentenced to be imprisoned for life, but the judgment was reversed on appeal to the House of Lords; but the prosecution answered its intended end; the prestige and magic influence of the great 'Liberator', as he was called, was destroyed; he himself henceforth spoke in more measured language, and the funds of the Repeal Association were nearly exhausted in the contest.

The return of the Whigs to power in 1846, and the advance of Mr. O'Connell gave to their party, introduced dissensions and differences among the aristocracy and supporters, over whom for forty years he had exercised an all-powerful influence. His health began to fail, and he became sour by opposition, as well as depressed in spirits by the example of failure and famine in Ireland. Early in 1847 he went abroad with the intention of spending some months in Italy, and of paying a devotional visit to Rome. He had not however proceeded further on his way than Genoa, when he suddenly sunk and expired on the 15th of May. His last words, were addressed to the Pope in compliance with his last wishes; and his body was conveyed to Ireland for interment. Besides three daughters, Mr. O'Connell left four sons, all of whom at one time or other had seats in Parliament. His eldest son Maurice, many years M.P. for Tralee, died in 1853; and his second son, John, after representing several Irish constituencies, was appointed in 1860 to the Clerkship of the Hanover Office in Dublin.

(Left and Times of Daniel O'Connell, by his son, John O'Connell.)

OEHLSCHLAGER, ADAM GOTTLOBB, the greatest poet of Scandinavia and one of the greatest European poets of the 19th century, was born on the 14th of November 1770, at Stockholm, a suburb of Copenhagen. The whole of his early life was clouded by himself with singular misfortune, first in an autobiography written to be prefixed to a German edition of his works and afterwards in a series of 'Erindringer' or 'Recollections' which were published in 1817, when his death by the hand of his own wife is informed in the 'Erindringer' of the boy's first inclination to swear, and how his mother checked it, of his strong propensity to pull off the bed-clothes, and a variety of similar particulars, the whole of which put together supply a varied picture of the life of a Danish boy at the close of the 19th century.

The name of Oehlenschläger is German; his father was from Krusendorf, a village in Silesia, where the family had produced a long succession of schoolmasters and organists; and his mother Martha Maria Flaming, was of Swiss parentage by the father's side, of Danish by the mother's. "Thus," says Oehlenschläger, "I am descended from both Danes and Germans, and it seems as if Fate had determined that I should find my vocation among the nations. My father had fallen much below the respectability of his ancestry by becoming a servant to Count Adam Gottlob Moltke, after whom the poet was named; but on his marriage with the countess lady's-maid he obtained by the count's patronage the post of organist at Frederiksberg, and afterwards of some subordinate position at the castle of that name, where he finally rose to be steward. Frederiksberg, one of the numerous palaces of the king of Denmark, a building which is said by some to have been erected from the plans of Inigo Jones, stands about two English miles from the western gates of Copenhagen, and is a favourite Sunday resort of the inhabitants of the capital. Here the early life of young Adam was passed amid scenes of great variety. In the summer Frederiksberg was often occupied by the royal family, and here the royal hand of music play on Sundays, and saw the royal company at dinner. In the autumn the place of the court was supplied by a legion of workpeople, busy with repairs; and in the winter the building was left in charge of the Oehlenschläger family, us, in short, the children of his paternal grandsire, who had been left the lordly mansion with two watchfires. 'That whole palace,' says Oehlenschläger, 'belonged to us, and I went about in the royal rooms, looking at the paintings and building castles in the air."

The name of Oehlenschläger in the winter was reading novels, which he got from a circulating library in Copenhagen, and of which he tells us that before he was twelve years old he had got through more than three hundred volumes. All that he read was Danish—a circum-"
only to each other when they did not wish the children to understand them.

Up to the age of twelve, young Adam had been very unfortunate in the article of schools; he was then taken notice of by Edward Storm, a Norwegian poet, who offered to give him a gratuitous education. He went to a public school in Copenhagen, if his father would be at the charge of his board. Young Adam soon began to write not only verses but even plays, which were acted by himself, his sister, and some play-fellows, on Sundays, in one of the rooms of his house. So much was it understood, that the school to which the boy had been admitted, laughed at his attempts; and Dichmann, another Norwegian, who was one of the masters, told him, to his great mortification, that he should have some time to prove that he could never be another Edward Storm. The education he received was designed to qualify him for a mercantile life; but when he left the school at the age of sixteen, he was glad of an accident which prevented his being placed in a counting-house, and readily persuaded his indolent father, who was now in much better circumstances than he had been, to allow him to study. In a year however he was tired of Greek and Latin, and having for some months spent all his spare time and money at the theatre, was seized with a desire to appear on the stage. Theatrical matters are generally held in low estimation in the serious light in a foreign city than in an English one, and at Copenhagen the management of the drama was treated with unusual solemnity. In Rabbeek's Lectures on the Drama, delivered in the University of Copenhagen, stage is a matter of private engine hardly secondary in importance to the pulpit. With the exception of the comedies of Holberg, the Danish Molière [Hansaas], the plays which were performed were then chiefly translated. "Of English pieces," says Oehlenschläger, "the first school of Copenhagen, was that much which Rosing was an excellent Sir Joseph [Joseph Surface], and 'She Stoops to Conquer,' in which Gielstrup was an incomparable Tony Lumpkin." He soon found however that he was not likely to rise to a much higher position than that of a walking gentleman, and the acquaintance of two young students, who had taken lodgings with the same landlord as himself, led him into a different line. They were the two brothers Oersted, afterwards so well known. Of the three, the eldest, Ores, occupied the stage; the second, a sort of companion picture to 'Hakan Jarl,' in which Odin- ism is shown in a more favourable point of view, and the latter a love tale of the middle ages. At Paris he was welcomed by Baggesen, who had before his own rise occupied the highest position in the Danish Parnassus; and when Oehlenschläger read to him the 'Palmatokes' the impetuous poet flung himself at his feet in transports of admiration.

On the 12th of April 1803 when Nelson attacked the Danish fleet off Copenhagen, Oehlenschläger saw the fight at a short distance, from the balcony of the Sea-Cadets' Academy, and he afterwards held the post of ensign in a volunteer regiment of students. He also published a small dramatic piece, 'The Second of April,' but it was of no merit. "That battle," he wrote, several years afterwards, "inspired the Danes with a taste for poetry, as the battles of Marathon and Salamis did the Greeks, and the destruction of the Armada the English in the time of Elizabeth. Some great disaster will forever be able to drive the mean, the petty, and parochial out of a nation's mind, and bring it in tune for the great and beautiful." In 1804 appeared a volume of poems, containing among other works, the play of 'The Battle of Salamis,' which once looked forward to as a writer of some note. The play, or rather dramatic tale, of 'Aladdin,' which followed, founded on the well-known story in the 'Arabian Nights,' captivated the public, in spite of some very obvious faults, by the general vividness of its tone, and raised his name very high in the list of the living Danish poets, if it did not place him at their head. He used often to say afterwards that in writing 'Aladdin' he had discovered his own 'wonderful lamp,' the vein of poetry which was to give him fame and fortunes. He received in 1806 a travelling stipend from the government, procured for him by Count Schimmelmann, and set out on a tour to Germany, to make the acquaintance of the band of literary men who at that time invested Germany with a halo. The second visit to Denmark was occasioned by the account of his travels, and of his intercourse with Göthe, Wieland, Tieck, Hegel, Voss, and other poets and philosophers. Up to his twenty-fourth year he had never written a line of German, but he was now so wrapped up in his illuminating friend's some notion of his poetical capacity that he translated his new compositions into German as fast as he wrote them, and somewhat unnecessarily occupied the time of many of them by availing himself of the permission to read his productions to them in manuscript, and take their opinion not only on the merits or defects of the structure and the poetry, but on the correctness or incorrectness of the language. It is not a little singular that productions so thoroughly Scandinavian in their tone and spirit should have been written in a foreign land and partly composed in a foreign tongue. 'Hakan Jarl' was written at Haile. It is a tragedy in five acts, on the fortunes of the old Swedish hero Ragnvald, who, when the Ottoman Turks were about to send a grand army against Scandinavia, was about to struggle between the two religions, Christianity and the belief in Odin. Nothing can well be more different than a tragedy of the old French school and such a tragedy as 'Hakan Jarl.' As the reader of 'Ivanhoe' finds himself, the reader of 'Hakan Jarl' is made as well as a part of the interested in the fortunes of Wilfrid and Rowena, but also well-informed and perhaps not less interested in the whole framework of the country around them, cognisant of the relations of the hero with the house of Saxons, of the eminence of the king and the Templars, of the ceremonies of a tournament and an ordeal, of the condition of serfs and Jews, so the reader of 'Hakan Jarl' sees before him the old tyrant superstition clinging to the wild religion of Valhalla, the young champion eager for the triumph, the Cross, the rude but independent Norwegian boor, the churning northern slave, the ambitious serf who carelessly espouses the new faith because it promises him a better career. An unceasing vivacity pervades the work, and there is not only pathos but humour; nothing can be further removed from the unvarying solemnity and systematic monotony which have by some been thought essential to the character of a tragic drama.

Oehlenschläger, before quitting Germany, was accidentally present at Weimar on the day of the double battle of Auerstadt and Jena, and in some danger when the victorious French entered the town. From Germany he went to Paris, where he composed what is by some regarded as his finest tragic poem, 'Adelheid,' a history of the Danish king Harald, son of the great Harald Bluetooth, and Julia Romanus, as two of the persons of the drama, affords the dramatist an opportunity of painting more than one variety of the artistic character. Few of Oehlenschläger's works merit the patient going through of judgments than this. Treated with disdain by Göthe, it was at last piously cavilled at by Tieck, and Cotta the publisher of Tübingen, after purchasing the German copyright, kept the play by him for years unpublished. Meanwhile the writer, after staying
some time in Italy, beginning to feel home sickness, returned to
Denmark after an absence of nearly five years, and read that
timeenhiscorometrics and the circles of the capital, among others to the king and queen of
Denmark, in presence of the leading members of the court,
in the queen's apartments. The play, when produced
in Germany, became one of the most popular on the stage, and
had a run of success of thirty years; and it also became a
favourite in Denmark. A translation of it into English, by
Theodore Martin, published in 1884, has met, we believe,
with a general welcome, and all English critics regard 'Correggio' as one of Oehlenschläger's principal titles to
fame.

Oehlenschläger had left Denmark in 1805, an eminent
rising poet. His reputation had risen higher and higher during
the years of the Revolution, and his influence, though he had
never been called upon, was without a rival. Before he set out on his travels he had
engaged the hand of Christine Heger, the sister of Camma
Rahbek, the wife of Rahbek the theatrical writer, whose
house on the hill (Bakkehus), a short distance outside the
city walls, had been since 1800, and continued till 1820, the
resort of the choicest literary society of Copenhagen. Rahbek
himself had in a fit of vexation just thrown up the post of
professor of aesthetics at the university, and Oehlenschläger
observed that he was left behind was being during
himself, if he pleased during the summer terms, which was a privilege he did not neglect to make use of. Being thus provided
with an income, he celebrated his wedding in an unusual
way, but precisely in the style that Rogers, the English poet,
was accustomed to say would have been if his, had he ever
ceased to be a bachelor. "On the 17th of May, 1810," says the
"Evenrider," "I dined with Christine at her
father's at Copenhagen, afterwards she and I drove by
ourselves to Gienioles, where Peter Hög, after I had shown
him the necessary papers, went with us to the church and
married us. We got into the vehicle again, man and wife,
drove off to the beautiful Christiansholm, to Sölyat, which
Count Schimmelmann had the kindness to offer us for a summer's residence. Upon the
notion that her husband had lost much by his dealings with the book-sellers, and under her advice he began to issue his
new plays and poems at his own risk, but soon convinced himself that he understood nothing of the publishing
business, and his wife no more; a conviction which says, however,
that his wife could never be persuaded to share.
During the next five years he wrote a number of plays of
various kinds, but was not quite satisfied in the composition
of abit, and his peace was disturbed by his failure in
the literary field. Baggesen, already mentioned as formerly the
head of the Danish Parliamnent, had left Denmark a little
before Oehlenschläger, with the deliberate intention, although
in his opinion not quite practical, of never returning to the
country, and of never writing another line of Danish. He
now changed his mind, came back, and, unable to see
with patience the throne of poetry occupied by another,
though one whom he had himself applauded, commenced a
series of critical onslaughts on Oehlenschläger, in
which the animus was painfully apparent. The public
became disgusted, Baggesen found himself in general dis-
avour, again expatriated himself, and finally died abroad.
It must however be owned, that Oehlenschläger stood in
need of a little criticism not too indulgent, and that he wrote
better after these attacks than he did at the time they
\commenced. In 1816 he made a second foreign tour to
Germany and to France, still using his pen when he halted, but
was driven home by severe sickness after a twelvemonth.
A long series of plays and poems followed, among which,
the most conspicuous was 'Nordens Guder,' the 'Gods of the
North' (published in 1819), an attempt to combine in one
consecutive whole all the scattered legends of the
Danish. The work was generally successful; and the most
of the work into English verse of very considerable merit by W.
E. Frye was published at Paris in 1845, and the poem
supplies much of the material for Pigot's 'Manual of North-
eerm' (published 1832), in which the same title was
written originally in German, was, on the contrary, of an
unmistakably inferior character. Oehlenschläger, who at the
age of seven-and-thirty took lessons in English from Andersen
Feldborg, a Dane long settled in Edinburgh, and well known
to Walter Scott, entered into correspondence with Sir Walter
Scott to express his warm admiration of his novels; and, on being
encouraged, sent the manuscript of his own novel to England
to be translated by Mr. Gillies, but in spite of the zealous
efforts that Mr. Gillies made to overcome his inability to find a publisher who would pay 100l. to the
author and translator for copyright. The failure was a for-
tunate one for the fame of Oehlenschläger, which would
have suffered much in England from a work so unworthy of
him.

In 1829, when at the age of fifty, he lost his father. "He
was vain of his son," says the poet in the 'Erindringer',
"but, like a sensible father, he never allowed me to see it;
only sometimes I detected the feeling when he had been
reading my poetical works. It embittered him to get into conversation
with strangers, and particularly with students on the bench
at the hill at Frederiksberg, and lead the conversation to
bear on me; when, if they said anything in my praise, it
tickled him much more than if they had spoken differently.
Many good-natured people were aware of this, and often
afforded this innocent pleasure to the old man."

The death of his father, and the death of Camma Rahbek
and her husband about the same time, threw a gloom over
Oehlenschläger's spirits, and they were soon afterwards
relieved by a singularly pleasant incident. He took for the
first time in his life, in 1829, a trip across the Sound to the
coast of Scania, thinking, as the steamer approached the
tiklange it was a sudden shock to the poet, and greeted his
sight over the waves from his earliest childhood at Frederiksberg, he had lived half a century, and been to
to Rome, without ever passing the straits. A brilliant reception
awaited him from all ranks in Sweden; addresses were pre-
vented to him at Stockholm, at Upsala, at Tornby, and even met him in a body in the high road with a professor at their
head. He attended the ceremony of the inauguration of a
rector of the university at the cathedral of Lund in company of
Tegner, whom he had met in Copenhagen by all as the first poet of Sweden, and was by many con-
idered to have surpassed in his 'Frithiof' any single work of
Oehlenschläger's. Tegner, in the course of the delivery of a
poetical address in hexameters, suddenly pronounced the
lines:

"Eklernemus Adam är bär, den Nordiske Kongerigets
Throneinviden int Diktingens verld ty Thomes o Goeboes.
(Adam of poets is here, the northern monarch of minstrels,
Hair of the componed Song, for now the seamstress in
Copenhagen, and in the presence of the crown that filled the
cathedral among whom were Oehlenschläger's wife and children, placed a
laurel crown on his head, amidst a bust of music and
the roar of cannon. The event, from all its circumstances,
assumed almost a national significance. Tegner and some
other eminent poets and persons appeared in person coming to Copenh-
agen. A few days after the King of Sweden sent the Order
of the North Star to Oehlenschläger.

Honours continued to shower on him after this; one of
which, the gift of a free lodging by the king, seems however to
ever have been availed of; "by a letter of King
Christian VIII," he tells us, "I granted me permission to live for
one summer in the house of the castle steward at Frede-
ricksberg," (the house which had been the official residence
of his father). "I wished very much to get the permission
tended to more summers than one. When I thanked the
king for his kindness, he asked me if there was not a garden
belonging to the house, and if I was not fond of gardening.
This gave me an excellent opportunity of bringing in my
petition. I answered that I should like very much to garden
if I could hope to gather some of the fruit afterwards. The
king said that if it were practicable I should have permission
to live there; and I then told him, in the lively tone in
which I have so much practised, if a good deal is practicable. He then gave me permission to keep the
house." Soon after, the poet tells us, he changed it for a
better.

In 1844, on another visit to Paris, Oehlenschläger was
repeatedly invited to court by Louis-Philippe, and presented
on one occasion to a gentleman, whom he afterwards found to be
King Leopold, who told him he had read all his works in
German, and invited him to Brussels. A visit which he
soon paid to Norway, and another in 1847 to Copenhagen,
were the triumphal progress of a sovereign in literature. On
his sixty-seventh birthday day his play of 'Amleth,' on the
same story as Shakspere's 'Hamlet,' was produced at Copenhagen.
It was completely successful, and the King of Denmark
wrote him a letter to congratulate him on his triumph. On
his seventieth birthday, the 14th of November, 1849, a grand
festival was given in his honour in the great saloon of the Royal Shooting-Gallery. All the leading poets of Denmark were present, and many of them wrote a song for the occasion. The young Danish poet, Oschilinshlager, wrote a poem on the occasion of his father's death, and it is said that he sent a copy of it to the poet, with a note saying, "I am sorry for you, cousin, but I am too lazy to write you a letter."

In little more than two months he was destined to die, and there was a general feeling of sorrow. The poet died on a Sunday evening, and his funeral took place on the following day. The funeral procession was a magnificent one, with musicians and military bands. The poet was buried in the cemetery of the town, and a monument was erected to his memory.

End of the passage.

---

In the general character of Oehlenschläger, as shown in his life, it may be seen that a high estimation of himself was not his occupation; but this in his case, as in many others, was grounded on real merit. The tone of his 'Autobiography,' not unfrequently reminds the English reader of that of Hogg, the 'Ettrick Shepherd.' Neither of the two was of the world; both were 'under the sky,' not of the world; both were respected by their countrymen, who by their conduct did no less honour to themselves than to the poets.
time the identity of the forces of magnetism and electricity had only been suspected. He now demonstrated "that there is always a magnetic circulation round the electric conductor, and that the electric current, in accordance with a certain law, always exercises determined and similar impressions on the direction of the magnetic needle, even when it does not pass through the needle, but near it." For this discovery he received the Copley medal of the Royal Society of London, and the French Institute presented him with one of its mathematical class prizes worth 360 francs.

In 1809 he wrote a 'Manual of Mechanical Physics,' a second edition of which was published in 1844. The relations and effects of his discoveries are now found in many departments of natural philosophy, scarcely any of which have not been enriched by his experiments. He made many important experiments on the compression of water, and invented an instrument by which liquids might be compressed with more certainty. He was the first to demonstrate the existence of the metal aluminium in alums, and made other chemical discoveries. In 1828-23 he again visited Germany and France, and also visited England. On his return to Denmark he founded the Society for the Distribution of Natural Science, one object of which was to send forth a body of popular lecturers to deliver courses of instruction in the most important towns of the country. He took an active part in the Scandinavonian Society of Natural History, and was president of it from 1842 to 1856. The Society of Natural Science, assembles annually in different parts of the country. He again visited England in 1846, during the meeting of the British Association at Southampton.

As he increased in years honours increased upon him. He was made a freeman of the City of London in 1852, and a corresponding member of the Academy of Sciences in the French Institute; and Director of the Polytechnic School at Copenhagen, which he had himself founded. In 1867 he was made Knight of the Garter, and in 1849 Knight of the Prussian Order of the Reward of Merit in the Arts and Sciences. In early life Oersted was associated with the poet Oehlenschläger, whose sister was married to his younger brother; and although devoted to experimental science, he took a deep interest in the progress of Danish literature. He was a constant reader for the newspapers and magazines. Acting upon the deep conviction that science should be the handmaid of religion, he did all that lay in his power to make the popular mind of his country acquainted with the facts of natural science. He wrote a lyrical and didactic poem called 'The Balloon,' which was translated into German. He was also one of the most popular lecturers of his day. He not only lectured in the universities, but for many years to large and small gatherings in the university to citizens and classes of ladies. A variety of Oersted's papers and lectures of a popular kind have been translated into the English language by the Misses Horner, under the title of 'The Soul in Nature, with Supplementary Chapters.'

On the 9th of November 1820 a jubilee was held in honour of the fiftieth anniversary of his services at the University of Copenhagen. On this occasion people of all ranks and opinions assembled round the noble old philosopher. The king of Denmark presented him on the occasion with a country residence at Frederiksberg, near Copenhagen. He lectured through the winter, but the following March he took a severe cold, which terminated in inflammation of the lungs. He expired on the 9th of May. The following is a biographical sketch of Oersted, to which we are indebted for some of the materials of this notice, was published by P. L. Möller, a translation of which is published with the English translation mentioned also. OERSTEDT, J. [Minneapolis, S. 1.]

OFR TAGEND. [Bot.: ostrida.] OFFENCES AND PUNISHMENTS. The punishments under the criminal law had been greatly mitigated prior to the year 1814. The sentences of death were still more from the establishment of an effective police in the metropolis by Sir R. Peel's Act, the 10 Geo. 4, cap. 44, which has been gradually extended to the whole of Great Britain and Ireland, though the number of executions has not decreased. The number of persons committing crimes without violence: Class 1, offences against the person; 2, offences against property, committed with violence; 3, offences against property, committed without violence; 4, malicious offences against property; 5, forgery and offences against the currency; 6, offences relating to the public revenue; 7, relating to the hireling classes, of which in 1850 there were 20,781 commitments, of which 20,162 were under class 1, 1354 under class 2, 15,478 under class 3, 1386 under class 4, 366 under class 5, and 1539 under class 6. In 1849 the number of commitments of which 20,623 were sentenced to capital punishment, and 34 executed of whom 21 were for murder. In 1840 there were 27,187 commitments, of which 21,484 were under class 3, and 19,473 convictions; of these 77 were sentenced to capital punishments, 9 of whom were executed, all for murder. In 1845 there were 24,303 commitments, of which 19,506 were under class 3, and 17,409 convictions; of these 49 were sentenced to capital punishments, and 12 executed, all for murder. In 1850, in England there were 26,515 commitments, of which 18,866 were under class 1, 20,192 under class 2, 21,533 under class 3, 236 under class 4, 650 under class 5, and 744 under class 6. Of the total there were 20,539 convicted, of whom 49 were sentenced to capital punishment, and 9 executed. In the preceding classes of which 4038 were under class 1, 2924 under class 2, 16,737 under class 3, 463 under class 4, 250 under class 5, and 7451 under class 6. Of the total 17,108 were convicted, of whom 17 were sentenced to capital punishment, and 8 convicted. In the preceding classes there were 11,192 were under class 1, 676 under class 2, 2150 under class 3, 49 under class 4, 170 under class 5, and 231 under class 6. Of the total, 3835 were convicted, of whom 3 were sentenced to capital punishment, and 2 executed. In 1856, the latest returns we have, there were in England 19,437 persons committed for trial, of whom 15,425 were males and 4013 females; of these, 4672 were acquitted or discharged and 31 were found insane; of the number convicted, 1384 were for offences against the person, 16,015 for offences against property with violence, 10,487 for offences against property without violence, 94 for malicious offences against property, 707 for forgery and offences against the currency, and 345 for offences against the public revenue. In the preceding classes and including misdemeanors; 69 were sentenced to death, of whom 16 were executed; 57 were transported for life, and 216 for terms exceeding ten years; 2158 were sentenced to penal imprisonment for terms varying from one month to one year; and 417 were sentenced to penal imprisonment from one month and under to not exceeding four years; and in this class, in the terms betwixt six months and one month or less, the numbers show a remarkable decrease from previous years; in 1850, the numbers were 7860, against 12,330 in 1849. In 1850, 16.500 in England and Wales, and 77 the smallest amount in any year from 1847; 222 were ordered to be detained in reformatory schools, and 127 were whipped, fined, or discharged on sureties. The great decrease in the number of commitments is probably to be attributed in a considerable degree to the extended provisions of the Summary Convictions Acts. On summary proceedings, the number of cases under the Criminal Justice Act, was 11,275, and under the Juvenile Offenders' Act, 2031. Altogether therefore there were committed in the year 1850, of whom were males and 33,363 females. The commitments were—19,278 for trial, 77,712 on summary convictions, 3794 for want of sureties, 15,052 remanded and discharged, 11,406 forScottish civil process, and 75,577 under the Mutiny Act. The total shows an increase of nearly 4000 commitments over those of 1855; but there is a decrease of 7000 in the number of summary convictions. Of the committals, omitting debtors and military prisoners, which reduce the number of cases to be considered to about 15,200 in the age; 11,991 of persons between 12 and 16; 24,886 between 16 and 21; 33,400 between 21 and 30; 20,973 between 30 and 40; 11,343 between 40 and 50; 5519 between 50 and 60; 6272 above 60; and 370 of whom the age was notcertified. Of these, 27,574 were convicted; of whom 12 could not write, 61,253 could read or write and imperfectly, 6108 could read and write well, 318 had received superior instruction, and of 4371 the instruction was not ascertained. The county and borough prisons are stated to be occupied to
contain 25,447 prisoners; the daily average of prisoners is 17,764, and the greatest number at one time was 23,026: but, though the margin there may be room enough, some prisons are terribly overcrowded.

In Ireland in 1856 the total number of persons committed or held to bail for trial was 7008, of whom 3076 were either acquitted or discharged. There were 2924 persons for offences against the person, 556 for offences against property with violence, 2694 for offences against property without violence, 78 for malicious offences against property, 75 for forgery and offences against the currency, and 1143 for other miscellaneous crimes. Of those persons 50 were sentenced to death, and 3 only executed; 14 sentenced to transportation for life, and 372 to other periods of transportation or penal servitude; 2798 to various terms of imprisonment; for 588 the whipping or discharging of the ears were prescribed; and 2035 were discharged on conviction. In the same year there were 25,461 cases heard at petty sessions or before magistrates, and 3959 persons were imprisoned for drunkenness.

In Scotland in 1856 the total number of offenders committed for trial was 3713. Of these 1046 were for offences against the person, 380 for offences against property committed with violence, 1942 for offences against property without violence, 79 for malicious offences against property, 85 for forgery and offences against the currency, and 611 others for miscellaneous crimes. Of the total number committed, 2723 were convicted, of whom 3 were sentenced to death and executed, 274 sentenced to various periods of transportation and penal servitude, 2170 to various terms of imprisonment, and 355 were discharged on conviction or discharge on conditions of good behaviour.

ODIUM, a genus of Plants belonging to the order of the Fungi, some of the species of which are found upon the human body and other animals. It is known by possessing a simple or branched mycelium, which is very minute and pellicular, aggregated into distinct masses slightly interwoven and articulated. The sporidia are simple and pellicular, and arise from the joint of the mycelium.

O. albicans, the Thrush-Fungus, is found in the mucous membrane of the mouth, fauces, and oesophagus of sucking children, and also occasionally in grown-up persons in a state of extreme exhaustion. The ulcerations, amidst the discharge of which this fungus is found, are usually called thrush. Although constantly present in this disease the fungus does not appear to produce the disease, but to be the result of the change of the mucous membrane.

It has been observed that the mucous membrane in this state constantly affords an acid reaction, and this acidity seems necessary to the growth of the fungus. The best acid is that which will be found in the fruits of the Végetaux Parasites. Several other species of Oidium have been described. The fungus found in connection with the recent grape-vine disease is an Oidium. [Entophita, &c.]

OIL-PLUM. [ELMIA.]

OIL-TREE. [BARRIA.]

OILS. The Fixed Oils are mostly products of animal organization, in the fat and adipose tissues; but are found also in plants, generally in the seeds, but in some cases in the fruit, as in the olive. They are composed of carbon, hydrogen, and oxygen, and are liquid or solid according to the manner in which these elements are disposed, most of them consisting of two compounds, a liquid called Olein, and a solid called Stearin, the hydrocarbon called Iparin. The Volatile Oils are mostly products of vegetable organization, and are so called on account of the ready manner in which they are volatileized by heat. Plants owe their peculiar odours to the volatile oils. They are divided by chemists into three groups: those which consist of only carbon and hydrogen, as oil of turpentine; those which contain oxygen also, as oil of cloves; and those which contain sulphur, as oil of garlic.

OKE, LORENZ, a celebrated Swiss naturalist, was born at Offenberg on the 2nd of August 1779. He studied medicine and natural history at Göttingen, and held the position of privat-doctor in that university. In 1807 he became extraordinary professor of chemistry in the university of Jena; thence he removed to Zürich, and afterwards to Karlsruhe, where he died. Oken was professor of natural history till his death. At the time he began to study natural science, the writings of Kant, Fichte, and Schelling were producing a deep impression on the minds of men, and the doctrines of nature and science, as well as of tradition in medicine, had applied the principles of the transcendental philosophy to the facts of the natural world, and by a process of thought endeavoured to give an explanation to the phenomena of nature. It was in this atmosphere that Oken had learned and preserved the true transcendental philosophy more or less guided his researches as a naturalist throughout his long life. His first work was published in 1809, and was entitled 'Elements of Natural Philosophy, the Theory of the Senses, and the Classification of Animals.' Another work by him, by the title of 'On Generation,' was published in 1805. In these works he endeavoured to apply a general theory of nature to the facts presented by the forms and the development of animals. In his classification of the invertebrates he included all the classes of animals, making each class of animals to represent an organ of sense. In his work 'On Generation' he first suggested that all animals are built up of vesicles or cells. In 1806 he published his 'Contributions to Comparative Anatomy and Physiology,' and pointed out the origin of the intestines in the umbilical vessel. In this year he made an excursion to the Harz Mountains, which resulted in an important thought. This may be described in his own language: 'In August 1806, he says, I made a journey over the Harz. I also observed the own phenomena of the crossing of a straight before me, at my feet, lay a most beautiful bleached skull of a hind. I picked it up, turned it round, regarded it intensely: the thing was done. 'It is a vertebral column!' He then referred back to his previous work and was whirling in its description of the vertebrae before mentioned, and since that time the skull has been regarded as a vertebral column.' This discovery was published in an essay on the 'Signification of the Bones of the Skull.' This essay, although it attracted little attention at first, laid the foundation of those inquiries which in the hands of Oken, Geoffroy St.-Hilaire, and Owen, have led to the establishment of those laws of homology in the vertebrate skeleton that are now a universally received branch of anatomical science. It was by the persevering use of the idea that flashed across his mind in the Harz, that Oken has earned for himself the title of "the father of morphological science."

While still a young man and deeply convinced of the importance of an ideal philosophy in explaining the phenomena of the external world, he wrote his 'Lehrbuch der Natur-Philosophie.' This work was published in 1809, and having gone through three editions, it was translated into English by Mr. Faulke, and published in 1847, by the Ray Society, with the title 'Elements of Physio-Philosophy.' In this work the author takes the whole field of natural science, and classifies the mineral, vegetable, and animal kingdoms according to his philosophical views. The transcendental philosophy has never been popular in England, and had it been published in this country it would have been despised. The transcendental philosophy, by the way, is generally held to be the most logical of all the forms of philosophy. The transcendental philosophy, by the way, is generally held to be the most logical of all the forms of philosophy. Moreover, in systems of writers on natural history in this country, so that this work has been frequently regarded as the offspring of a diseased imagination rather than the cool decisions of a philosopher. Nevertheless, the author was pleased at the translation, and wrote a preface to the English edition. Of however little value this work may be as an introduction to modern science, it is interesting as a document in the history of a great mental movement, and contains the germs of those principles which are now regarded as the secure generalisation of well-observed facts.

From the date of the publication of this work to the day of his death, Oken unceasingly contributed to the literature of natural history. In the year 1817, he started a natural devotion in Aachen, and continued it for thirty years, and which contains a large series of his papers on every department of natural history. Though a transcendentalist in philosophy, he was an energetic and acute observer, and has contributed largely to the individual history of the animal kingdom.

He was greatly respected throughout Germany, and it was at his suggestion that the first meeting of natural philosophers took place in 1822. The German Association which thus gathered together men who aspired to form one large body of the natural history of Europe has imitated this example with great and increasing success. Oken died full of years and honour, at Zürich, in August 1847. After his death his son, Carl Oken, was also a naturalist.

OLD RED-SANDSTONE. The following table and account of the Old Red-Sandstone Formation is given by Professor Austed in his 'Elementary Geology':—
by this formation; and its vast thickness is well displayed in the hills crossed by the new road from Leominster to Hereford. In the northern portion of the range, and near the mouth of the Towey and the parishes of Westmorland, the limestones are most fully developed, becoming much thicker and almost more crystalline than in other parts.

In Scotland the uppermost beds are highly arenaceous, and often consist of sandstone conglomerates. The intermediate calcareous and sandstone, and finally the conglomerate and calcareous sandstone, are in some places distinctly stratified, and in others having a more irregular composition, yielding unequally to the weather, and exhibiting a brecciated aspect. It contains masses of chert exceedingly hard, and these, from the manner in which they are incorporated in the rock, appear to have been of contemporaneous origin. The bed is very indurated, and is very persistent, being found both in Moray and in Fife, localities 120 miles apart.

The middle group of the Old Red-Sandstone of Scotland, corresponding to the Cornstone of England, is developed in Forfarshire, in Morayshire, and in the Gray-Sandstone of Balradder, where the lower beds are absent. It is represented as consisting, for the most part, of rocks of a bluish-gray color, sometimes, as at Balradder, resembling the silurian mudstones, at others forming a hard fissile flagstone exported as a paving-stone, and occasionally appearing in beds of friable stratified clay, easily washed away by the sea. The colour however throughout is gray, and in this respect differs essentially from the English-marl and contemporaneous beds, which are chiefly red and green marls.

The base of the whole system is represented by Mr. Miller as consisting of an extensive and thick conglomerate rising into a lofty mountain-chain in the county of Caithness, and containing 3000 feet of granite, while in the Morayshire, but a great thickness of arenaceous strata, containing conglomerates of various magnitude, intervenes between these and the middle beds.

The Devonian Beds present a series so distinct that no relations of mineral or mechanical condition can be traced between them and the Old Red-Sandstones. The upper beds on which the culms of Devonshire repose, consist of coarse red flags and slates, sometimes alternating with or superimposed on others of like kind; and while the English beds are to be sought among the calcareous slates of Cornwall and South Devon, the calcareous slates are occasionally fossiliferous, and are based upon an impure limestone. The Plymouth limestone in the south, and a group of coarse arenaceous beds in the north of Devon, together with the general series of Cornish rocks, are all included among these calcareous slates. Throughout the whole series fossils occur, but they are very unequally distributed, being locally abundant, and almost without trace in others. The calcareous character of many of the beds are sometimes much altered, and frequently obliterated. (Anecd.)

The Old Red-Sandstone is largely developed in Ireland, and it is peculiarly interesting as presenting all those parts of the series which are found in the central and southern parts of England. This formation is well represented in Ireland by a series of beds consisting of 1500 feet of strata. They are principally composed of a yellowish-sandstone alternating with shale and calcareous beds.

The Devonian or Old Red-Sandstones of Russia occupy a tract nearly as large as the whole of the British Islands. They rest conformably upon low plateaux of silurian rocks, and attain a height of from 600 to 900 feet above the sea level. This formation is repeated with nearly the same mineral characters and organic remains in America. It is found in both North and South America.

The following are the genera of the Invertebrate Fossils found in the Devonian Group, as given by Mr. Tennant in his 'Stratigraphical List of British Fossils':—

**Amphora.**

- *Manum erioborum*, Goldf.;
- *Scyphia turbinata*, Goldf.;
- *Amphipus tortuosus*, Phil.;
- *Astarta Blainv.,* 3 species;
- *Aulopora conglomera*, Goldf.;
- *Canemophora ramosa*, Phil.;
- *Canemophora rotunda*, Phil.;
- *Cystophyllum*, 2 species;
- *Cystophyllum*, 2 species;
- *Cystophyllum*, 2 species;
- *Fea's*, 4 species;
- *Fea's*, 4 species;
- *Glaucosoma bipinnata*, Phil.;
- *Glaucosoma bipinnata*, Phil.;
- *Glaucosoma bipinnata*, Phil.;
- *Glaucosoma bipinnata*, Phil.;
- *Glaucosoma bipinnata*, Phil.;
- *Glaucosoma bipinnata*, Phil.;
Echinodermata.

Adelocrinus hystricus, Phil.  
Cystocrinus, 8 species.  
Tetrametra ulvae, Goldf.  
Cystocrinus, 2 species.  
Platycrinus, 2 species.  
Tessuitocrinus macrodactylus,  
Petriotretus costulatus, Goldf.  
Corbula Hennahali, Sow.  
Oenocidaris, 7 species.  
Cyphoidea, 3 species.  
Megaster, 8 species.  
Morida, 3 species.  
Conchylii Monomorpha.  
Avicula, 9 species.  
Pecten, 8 species.  
Brachiopoda.  
Arctica, 19 species.  
Cuculeus sandallina, Lam.  
Cheopis, 3 species.  
Leptana, 7 species.  
Orthis, 16 species.  
Rostropoda.  
Acroclia specialis, Phil.  
Buccinum, 4 species.  
Eocyclus, 3 species.  
Nerita, 2 species.  
Natica, 2 species.  
Pleuronecia, 2 species.  
Scripionella, 3 species.  
Terobratala, 31 species.  
Gasteropoda.  
O. sagitata, (Sipus Loligo, Linnaeus), with an elongated body; peduncles of tentacular arms without suckers; extremities of their clubs armed with numerous sharp spines.  
This species is very rare on the British coast, but Morris, Forbes and Hanley record two instances of its recent capture.  
0. dornata (Loligo sagitata, Lam.), Delle Chiaje.  
It has an elongated body, and the peduncles of the tentacular provided with suckers throughout their length.  
This squid is often called in British catalogues "Loligo sagitata," but it is frequently found on the coasts of Great Britain.  
It has been made the subject of an elaborate memoir on the anatomy of its nervous system by Mr. Albany Hancock.

O. bubula (Ball), has a short body; suckers confined to the clubs of the tentacles, minute, and 4-ranked on their extremities.  
It has been found in Dublin Bay, and was first described by Dr. R. Ball of Dublin.

Forbes and Hanley, History of British Mollusca.

OMPHALEA, a genus of Plants belonging to the natural order Euphorbiaceae. The seeds of one of the species are said to be estable when the embryo is extracted, but if this is not done, they are too cathomic for food.  
On the authority of Mr. W. McLeay, Dr. Lindley says this nut is most delicious and wholesome, and that it is known by the name of Cob-nut or Hog-nut in Jamaica. Other euphorbiaceus seeds have the same properties.

O. triandra is a Guayana plant with a white juice, which turns black on drying, and is then used as ink.

OOLITE. [GEOLOGY; OOLITE.] At one time it was supposed that the little round masses which are so characteristic of the Oolitic Formation were portions of limestone which had gathered round various forms of minute fossil animals. It was suggested that these organisms were probably Foraminifera. Recent microscopic investigations have however shown that these little round bodies are purely inorganic, and that they are formed in the same manner as the larger nodules of the magnesian limestone.

The oolitic deposits are divided naturally in England into three parts, the Upper Oolite resting on the Kimmeridge Clay, the Middle Oolite representing the Oxford Clay covered by the Coral Rag, while the Lower Oolite is more variously composed of numerous bands of clay, sand, and limestone.

The Upper Oolites, called on the Continent the Portlandian Group, are, so far as the British Islands are concerned, almost entirely confined in their development to the south of England, only that stratum of clay which usually forms the base of the group being exhibited in Yorkshire, in the vale of Pickering.

The group of strata containing the Portland stone, and exhibited in Portland Island, includes several layers of coarse earthy limestone, which rest on a bed of siliceous sand, mixed with green particles. This is called the Portland Sand, and sometimes attains a thickness of as much as 60 feet in the west dismantled, and forms a complete passage into the underlying clay.

Above the coarse limestones of the lower part, which usually consist of alternate hard and soft layers to a thickness...
of 50 or 60 feet, there are three beds of serviceable stone, interspersed with clayey or siliceous bands. Fossils occur in all these strata; but they are rare in those beds of the stone which are worked to advantage for economical purposes.

In the upper part of the Portland series there occurs a very interesting bed, about a foot in thickness, of a dark-brown substance, containing much earthy lignite. This bed, called the "weathered bed," is a very thin bed, and is a feature that some distant period nourished the roots of trees, fragments of whose stems are now found fossilised around it. Wherever the dirt-bed is laid open to extract the subjacent building-stone these remains of trees occur, and they are placed at such distances from one another as trees growing in a modern forest.

It results from the circumstances of this deposit, that the surface of the Portland stone, at the termination of the Oolitic period, must have been for some time dry land, and covered with a forest; and we have a kind of measure even of the duration of this period in the thickness of the dirt-bed, which has accumulated more than a foot of black earth, loaded with the wreck of its former vegetation. The regular and uniform preservation also of this thin bed over a distance of so many miles, shows that the change from dry land to the state of a fresh-water lake or marsh (which the nature of the overlying rock proves to have succeeded the period of dry land) was not accompanied by any violent destruction. They are sometimes seen,north-east, together with the trees which lay prostrate on its surface, must inevitably have been swept away had any such violent cataclysm then taken place.

The Upper Oolites consist of a blue, slaty, or greyish-yellow color. It frequently contains a considerable quantity of silenite, or "crystallised sulphate of lime. It usually effervescences with acids, and exhibits in tolerable abundance both vegetable and animal impressions, although its fossils are rarely in such good condition as to be preserveable in a collection. It is a bed of great thickness; horizontal, or nearly so, in its stratification; extremely persistent in its peculiar mineral and fossil characters, but not very extensively developed either in England or on the Continent. The name, Kimberidge Clay, has been applied to it because it is well exhibited at Kimberidge Bay, and near the village bearing the same name in the Isle of Purbeck.

At this spot there are also found, alternating with the clay, certain beds of highly bituminous shale, occasionally used for fuel, and locally known as the Kimberidge Coal. There are many beds of lignite found in the Oolites, but these are perhaps the most remarkable, next to those of the lowest Oolite deposits of Yorkshire and Northumberland.

Among the foreign rocks of this part of the oolitic period are, the Calcaire de Blangy, on the coast of Normandy; 2nd, the upper beds of the Jura, in Switzerland; and 3rd, the Gotland beds.

On the banks of the Donets, in Southern Russia, there are beds of Oolitic Limestone of light-yellow colour, which appear to belong to this division of the secondary series.

The Middle Oolites consist for the most part of a thick bed of clay, called the "Oxford Clay," widely expanded throughout England, and met with also in the same form on the Continent, and a series of overlying limestones, chiefly remarkable for the abundant remains of coral found in them.

The upper beds of the middle Oolitic Series are partly calcareous and partly sandy, the former consisting chiefly of a very interesting group of corals known under the name of Coral-Rag, and the latter, the sandy beds, or calcareous grits, often more or less intermixed with corals, and containing thin lamine of clay sometimes passing into irregular bands of hard and tough marly rock. This calcareous matter seems entirely due to the presence of crushed and decomposed organic remains.

The thick-bedded limestones of the towns of Calne and Steeple Ashton, and in the surrounding neighbourhood, the coals of the Coral-Rag are found in greatest abundance and perfection; and this part of our island, at the time of the deposit, has clearly existed in the condition of a coral lagoon, of which the beds of hard limestone, about 40 feet; large portions of it are frequently made up of the remains of a single species, and an earthy calcareous free-stone, sometimes used as a building-stone, and full of fragments of shells, rests immediately upon it, and is surrounded by a fine-grained ferruginous sandstone, slightly oolitic in structure, and containing a few fossils, marking the close of the Middle Oolitic period.

In the north of England the contemporaneous bed is a calcareous sandstone, containing corals, and of the name of Maltese, in Yorkshire), including a considerable proportion of the fossil remains of shells, both bivalves and univalves. The bed never loses its coralline character, and may perhaps be considered an imperfect coral reef, one extending from the south-west of England to what is now the right bank of the Humber.

The Oxford Clay is a very important member of the oolitic series, attaining a thickness of not less than 500 feet, and spreading over a great part of England—more especially occupying the fen districts in the counties of Cambridge and Lincoln, which appear to be partly caused by the union of this bed with the Kimberidge Clay, producing a wide expansion of flat and undrained country. The same deposits are well seen at Weymouth; and they cover an important part of the East Riding of Yorkshire. The stratification throughout is nearly horizontal and undisturbed, being conformable with that of the formations immediately above and below it.

The appearance of the Oxford Clay is that of a stiff pale-blue argillaceous bed, containing a large proportion of calcareous matter, and a more or less abundant mixture of iron pyrites. Numerous organic remains are found in it, which are sometimes preserved in the clay itself, but more frequently form a nucleus, about which iron pyrites have aggregated. Those preserved in the clay have been generally found in a very rotten condition.

The Lower Oolites admit of considerable subdivision in the British Islands, but the details seem to be rather of local than general interest; and though partially extending to Normandy, are by no means universal in other parts of Europe.

1. The Cornbrash (the uppermost bed) consists of a variable thickness of clays and sandstones, which ultimately pass into a thin rubble stone, tough and occasionally crystalline.

2. The Forest Marble, which consists of carbonate of lime, has been extensively quarried.

3. The Great Oolite, consisting of a variable series of coarse shelly limestones.

4. The Bradford Clay, consisting of a pale-greenish clay, containing a small proportion of argillaceous matter, and including thin slabs of brownish limestones.

5. The Great Oolite is separated from the next bed, containing amongst them the clay used in the manufacture of cloth under the name of Fuller's Earth, and also a thin calcareous flag (the so-called "Blythefield Slate.") This latter has long been known as "Oolite" is remarkable for containing the remains of Marsupiata Animals. [MARSUPIATA.]

6. The Inferior Oolite is the last of the series of oolitic limestones. It is employed to a great extent as a building-stone. Its representative in France is the Caen Limestone.

The oolitic system embraces also the formation called Lias. In England it consists of a series of strata in which an argillaceous character predominates throughout; it also contains limestone mixed with clay. It seems to form four principal members, which are thus described by Professor Ansted.

"The Upper Lias, or Alum-Shale, is best seen at Whitby, and on the Yorkshire coast, and it attains there a considerable thickness. It consists of three distinct parts: the lowest division including soft shales, extremely fossiliferous, which are separated from the uppermost series, also composed of incoherent clay beds, by an intermediate stratum of hard shale, about 30 feet thick, containing a quantity of the mineral called jet, and also occasionally large fragments of the bituminised wood of coniferous trees. The jet itself is but a peculiar form of carbon, and there can be little doubt that it is to be traced both on the coast of Yorkshire and at Lyme Regis, that there have been found the most remarkable and interesting of those fossil remains of extinct animals, for which the formation is so celebrated. The presence of alternate beds of limestone and soft shale is usually characteristic of the lias in the different parts of England where it is most developed. The dark bluish-grey colour, united with the singular riband-like structure, is more particularly remarkable in the upper beds of the formation, and is well seen..."
at Lyme Regis, Whitby, and Barrow-upon-Soar, in Leicester-
shire.

"The principal locality of the middle beds of the lias is the
neighbourhood of Cheltenham, where the marlstone of
Dumbleton Hill is crowded with interesting organic re-
manis. It is made up of alternating layers of coloured clays
and sandstones, which are occasionally calcareous, and of
beds of impure limestone.

"This part of the series is also represented in the north of
England, where it has an average thickness of about 150
feet, and consists of sandy shales, of which the upper portions
are distinguished by the presence of several bands of gar-
lace-like iron nodules.

"Lower Lias Shale.—The great mass of the lower division
of the Lias is found in the middle of England, and
consists of impure limestone bed and finely laminated shale,
in which are calcareous bands and concretions. These form
the base of the series, and gradient downwards to a whitish
sandstone, belonging to the uppermost beds of the New
Red-Sandstone system. The transition is different again in
the south of England; and at Lyme Regis marls of a light-blush
colour represent the upper beds of the New Red-Sandstone
and pass into the Lias Limestone by a succession of dark slaty
marls, which are overlaid by a number of gray calcareous
beds, and these again by slaty marls of the upper series.
The Marls from the Lower Lias Shale are not present in
this part of the deposit in their ordinary form.

"The lowest portion of the Liasic System occasionally
consists of a very thin bed, in some places entirely made up of
of these fossiliferous beds, especially the remains of trilobates,
but sometimes passing into a white micaceous sandstone, still
recognisable as the same bed. This bed was first observed
underlying a small patch of Lias, near the town of Ault
(situated on the left bank of the Severn, nearly opposite
the mouth of the Wye); but it has since been recognised at
Azmough, in Devonshire, and in other parts of England
further north, having a total range of upwards of 100 miles.
It is rarely more than 3 or 3 inches in thickness, but in
variously occupies the same geological position, and is for
the most part so exclusively composed of organic remains,
that a long period must have been required for its formation.
In some parts of the country, and especially in Gloucestershire
and Worcestershire, the passage of the Lias into the underly-
ing beds of New Red-Sandstone is marked by the presence
of calcareous flagstones, called Lower Lias Limestones; and
these usually alternate with laminated shales, the whole in
that case forming together the lowest deposits of Lias.

"On the Continent the Lias is frequently found, and the
upper beds resemble those developed in England; the middle
however are usually more calcareous, and the lower sand-
y, and these latter, sometimes, as in Belgium, pass insen-
sibly into the upper New Red-Sandstone. The town of
Luxembourg is built upon a hard sandstone of this kind, and
these beds pass into the rock called Arkesite, a peculiar and
often metaliferous metamorphosed deposit, occurring where
the Lias sands come in contact with crystalline rocks. For-
siles have been found in South America, and also in Northern
India, attributed to the period we are now considering.

"The Lias is a formation exceedingly rich in fossils; and
amongst them are representatives of all the principal natural
groups. Corals however are exceedingly rare, and of small
size. Eocercites are numerous and abundant, especially the
Pentacrinite, which attached itself to floating wood. Radi-
atid animals of other kinds characterise parts of the deposits,
and of these the Diadema is an example. Insects and Crust-
aceans have been frequently found. Star-Fishes are common
in the marls of England.

"Both univalve and bivalve shells of various kinds are
characteristic either of the whole deposit or of different beds.
The Spirifer is one of the latter species of a genus
represented far more abundantly in more ancient deposits,
while the Placogaster and Plagiogaster are among the ancient
representatives of more recent forms. The Pentamerus is an
example of a similar kind; and the Ammonites and Belemn-
ite, are essentially characteristic cephalopodous shells, infi-
nitely more common in the Lias, as it is the great part of the
oolean period. Above 170 species of Mol-
les have been described from the British localities only,
and of which as many as 70 are Ammonites.

"The most common in some parts of the Lias, and as many as 60 species in all have been described; of
these many resemble the shark, but none seem to have
attained very gigantic proportions. This however was not
the case with the Reptiles, which during the period in ques-
tion were equally remarkable for their large size, voracious
habits, and incredible abundance. Many species belonging
to natural orders of these animals long since lost, were then
widely dispersed; and many other species existed of genera
now common in distant parts of the world. The Flying
Reptile is a striking instance of the mammoth structure. The
swimming and indeed strictly marine monsters named Ichthy-
saurus and Plisontosaurus, are other examples." [Ptyco-
ductiy; Ichthyosaurus; Plisontosaurus.]

The following is a list of the Fossil Genera found in the
Oolitic Beds:—

**Planta.**

Alethopteryx, 2 species. *A. pseudopleura* Preal., *A. pleura* Preal.
Bemisia ocellata, Buck.
Brachyphylum mammillare, Lindl.
Butterflya squamosa, Brong.
Carpithecus, 2 species.
Cytophylax, 2 species.
Dictyophylum rugosum, Lindl.
Eucyclas, 2 species.
Lilia lanceolata, Buckm.
Lycoptera, 2 species.
Naiades, 2 species.
Neotrophus leonardus, Lindl.
Pachypteryx, 2 species.
Pectoptera, 11 species.
*Amphora.*

Spongocoma, 7 species. *Zoophyta.*

Alecto dichotoma, Lamx.
Aegonopsis cristata, Lamx.
Agarica lobata, Goldf.
Arctes, 3 species.
Carapx, 3 species.
Ceratopoda clavata, Goldf.
Corynosa, 2 species.
Crinipora, 2 species.
Eunomia radiata, Lamx.
Fungia orbiculus, Lamx.
Heteropora, 2 species.
Idomona triquetra, Phil.
Echinodermata. [Echinoderma.]

Arachnida.

Serpula, 17 species.
Vermicularia, 5 species.
Vermilux rubra, Sow.
Pollicps, 3 species.
Cirripedia.

Insecta. [Insecta, Fossil, S. 1.]

Crustataceae.

Acetes, 4 species.

Conchaferia Monomorqya.

Amphidusa, 3 species.
Anatina rudata, Sow.
ap. *A. antennata* Sow., sp.
Apicalia, 9 species.
Arata, 16 species.
Cardinica, 15 species.
Cardium, 15 species.
Cardina, 3 species.
Corbula, 4 species.
Curculites, 14 species.
Cyprinodex solida, Lycet.
Cythere, 2 species.
Gastropoda tortuosa, Sow.
Hippopotamium pousorum, Lutraria, 5 species.
Sow.
Leiocopa, 11 species.
Lepadinae, 4 species.
Lucina, 4 species.
The Fossil Cephalopods are numerous, and in the bygone ages of the world appeared to have been powerful instruments for keeping down the other tribes of ancient Testaceans, Crustaceans, and even Fishes: for many of them—
certain Orthoceras and Ammonites for example—afford every evidence of the most rapid dimensions. In the periods prior to the Chalk Formation, and at the time of its deposition, were the agents employed for this purpose, and were succeeded in the Tertiary period by the Fossil Trachelpoids, which are either entirely absent or very scarce in the Secondary and Transition series, while the Fossil Cephalopods occur but rarely in the Tertiary beds. The extinct Ammonites, Baculites, Belemnites, Hymenoptera, Tesnata, and Scaphites, will readily occur to the fossil zoologist as some of the most curious fossils of the period. The Foraminifera, formerly placed by D'Orbigny in this class, are now no longer regarded even as Mollusca. [FORAMINIFERA, S. 2.]

**Ophiocephalus** (from ὀφίς, a snake, and κεφαλή, head), a genus of Fishes belonging to the division of Acanthopterygii, characterized by having labyrinthiform pharyngeal, and capable of living for a long time out of the water. The species inhabit India and China. [AMBARAS, S. 1.]

**Ophiocoma**, a genus of Animals belonging to the order Echinodermata, to the family Ophiuridae, and to the tribe Ophioidei. The rays are simple, squamosous, not prolonged into the disc superiorly, and separate at their origins beneath by small quadrate plates. The species are called Brittle-Stars on account of their fragility. They are very difficult to preserve. Professor E. Forbes recommends their being placed in fresh-water as soon as caught, which quickly destroys them; and after they have been in it an hour or so, to dip them rapidly in boiling water. They are then to be dried in the sun, or in a current of air. The following are the species found in the British Isles by Mr. Forbes in his *History of British Star-Fishes*:

**O. neglecta**, Gray Brittle-Star. Disc round, flat, imbricated with small smooth scales; two oblong parallel touching plates opposite the origin of each ray; upper ray-scales small, lateral ray-plates bearing four or five spines each, which are equal in length to the breadth of the ray. This species is not uncommon on all parts of the British coast.

**O. Balli**, Ball's Brittle-Star, was first discovered in Ireland by Dr. Ball.
"Tait's Magazine" in 1831. In 1834 she published the novel of Adeline Mowbray; or Mother and Daughter, in 3 vols., which added considerably to her reputation, and some passages of which are highly pathetic; but still she wanted art in grouping and developing her characters, and in combining her incidents. In 1850 "Simple Tales," in 4 vols., were published, in which the author's principal theme is a螺丝ing, an artlessness that steals into the heart, and language easy and simple though not always strictly accurate, there is still the same want of logical coherence; the tales want reality. The characters are all-defined and often unconvincing, yet the "Raffian Boy" and "Murder will out" will always produce an interest. In 1807 after the death of her husband, she returned to the home of her father. In 1808 she published "The Warrior's Return and Other Poems," and in the following year "Bardo," a continuation of the careers which he prefixed a memoir. In 1812 appeared "Temper," a tale in which she introduced many of her impressions of France; and in 1813 "Tales of Real Life," which however are not more real than her former tales. In 1816 Valentine's Eve, a novel in 3 vols., was published, developing some of her religious views, now becoming more decided. In 1818 "Tales of the Heart," and in 1822 Madeline, neither of them rising above the average of the preceding. Her next work, the "Lying," appeared in 1825, and was dedicated to her father; they consist of short tales, made for her avowed purpose, with dissertations, and show more decidedly than any the great defect in her reasoning powers, though all evince the most precious intention.

Early in life Mrs. Opie had been intimate with the Quaker family of the Fryes, particularly with Mrs. Fry, and through them with the Gurneys. In 1814 a letter from J. J. Gurney appeared in which she expresses her mind on the subject, she commenced attending the Quaker meetings, and in 1825, with her father's consent, she formally joined their society. In 1826 her father died, but she continued to make Norwich her abiding place, varied by frequent visits to her friends, to Scotland, and to the South of England. She had been a member of the society she had joined, but did not give up her literary pursuits. She still wrote occasional poems, and in 1823 "Detraction Displayed" was published. In 1830 she visited Paris, and her old political feelings seem to have revived. She wrote some verses on the tricollar, addressed to Lafayette, in which she says that at the sight of it, "I seem to feel youth's hours return." In 1830, on the exertion of Charles X., she again went to Paris, and has given a lively account of what she saw. In 1833, "Lays for the Dead," a volume of poems, was published. In 1835 she made a tour to Belgium and Switzerland, of which she gave an account in "Tait's Magazine," in 1840. She continued active in her old feelings for some years, contributing occasionally, as she had done throughout her life, to cause her periodical works, and after an illness of some duration, she died at Norwich, Dec. 2, 1853. Her life has been written with much care by an attached friend, Miss C. L. Brightwell, and published in 1855.

ORANGE, the Principality of, included the town and neighbourhood of Orange in the south of France. René de Nassau, nephew and successor of Philibert de Chillon, prince of Orange, was killed at the siege of St. Dizier in 1444, and left his heritage to his cousin William of Nassau, the founder of the republic of the Dutch United Provinces. After the death of William III, king of England, the principality passed to Frederick, king of Prussia, William's eldest son. The succession, however, was ceded to him by Louis XIV. at the peace of Utrecht. [Nassau, House of.] The principality then merged in the province of Dauphiné, and is now included in the Department of Vaucluse.

ORANGE TRIBE. [Avanttiaceae; Citrus.] ORCHIS, a genus of Plants the type of the natural order Orchidacea, and belonging to the tribe Orchideae. The old Linnaean genus Orchis is now divided into many genera [Cypripedium, etc.]; the number of species still retained under this designation. The tribe Orchideae is distinguished by the pollen grains being divisible into lobes, which are waxy and definite in number. The anthers are usually united, and the genus Orchis belongs to a section of this tribe, in which the pollen is united in a rosetting process between their bases. In Orchis the perianth is ribboned and hooded; the lip 3-lobed, spurred; the glands of the stamens of the pollen-masses are in a common pouch. The following is an arrangement of the British species according to Babington:

- Glands of the pollen-masses separate; lip erect in
  motivation.
- Bracts mostly 1-nerved; root-knobs undivided.
  ↑ Lip, 3-lobed; lobes broad and short.
- Orchis Morio, Green-Winged Meadow-Orchis. O. maculata, Early Purple Orchis.
  ↑ Lip 3-lobed; middle lobe dilated, bivalved, and often with an intermediate tooth.
  ↑ Bracts with three or more nerves; root-knobs undivided.
- O. laevigata.
  ++ Bracts with three or more nerves; root-knobs palmat.
  ** Glands of the pollen-masses united; root-knobs undivided.
  ↑ Lip erect in motivation.
- O. pyramidalis, Pyramidal-Orchis.
  ↑ Lip spiral in motivation.
- O. hirincina, Lizard-Orchis.

(Continued on Page 483.)
ORE 483

The valleys of the Clarnet and Umpqua rivers, while the main chain forms the valley of the Willamette. Other offsets, directing streams to the sea, turn down toward the Coast Mountains. This middle section of the state differs considerably from that west of the Cascade range. The hills are barren, but in the valleys of the Columbia, Willamette, and Siskiyou rivers the soil is generally fertile, and in some places even luxuriant. On the high plains of the Willamette Valley, and on the prairies of the Columbia and Siskiyou rivers consists of rolling prairie land, and affords good pasturage. The southern portion of this middle section is for the most part broken and desert, with scarcely a tree or vegetable. The general elevation of these plains is from 1,000 to 2,000 feet above sea level.

The Rocky Mountains have been noticed elsewhere. [Rocky Mountains.] They are of great altitude, and only one practicable pass has been discovered over them along the International line. This, known as the Klamath, South Pass, occurs at the south-eastern extremity of Oregon, and is that crossed by the great stream of overland emigration to Utah and California. The country immediately west of the Rocky Mountains is everywhere broken by great spurs from the main chain, and though in some places partially timbered, is for the far greater part rocky, barren, extremely variable in climate, and incapable of permanent settlement.

The principal river of Oregon is the Columbia, which forms the boundary of the state along the entire distance from the Umpqua Territory and Washington, and is not only common to both Territories, but receives all the rivers of both which rise east of the Cascade Mountains. [Columbia River.] The Siletz, Siskiyou, or Lewis River, sometimes called the Southern Fork of the Columbia, also contributes to the flow of the Columbia at the smaller branches which rise in the Rocky Mountains between 42° and 43° N. lat., and flows first west and then south through Oregon, passing into Washington near 117° W. long., after a very serpentine course of nearly 800 miles. The Siletz in its course through Oregon receives numerous affluents, all near or nearly all of which belong entirely to this Territory. Of these the principal are the Wapatoes, Siletz, and Siskiyou, on the right, and the Malheur on the left. Most of these rivers are navigable, and have considerable value for navigation. The Willamette, which rises on the west side of the Blue Mountains near 43° 30' N. lat., is one of the most important tributaries of the Columbia; it has a generally northern course and enters the river nearly opposite to Fort Vancouver, considerably below where it becomes navigable; is itself navigable by small vessels for a considerable distance; and drains one of the most fertile valleys in the Territory. The rivers which rise west of the Cascade Mountains are all navigable, and have considerable value for navigation. The principal are the Umpqua and the Clarnet. The Umpqua, which, after the union of its two head branches, flows nearly west to the Pacific, into which it falls by Cape Gregory, about 43° 54' N. lat., is in its lower course a wide but deep river, forming the boundary of the Columbia on the north, and the waters of Oregon which fall into the Pacific, has its mouth obstructed by a sand bar. The Clarnet, the most southern river of Oregon, is also the longest south of the Columbia; but there are few settlements along its banks, and its navigable capabilities are very limited.

Geology.—Of the geological features of Oregon only very partial examinations have been made. The mountain ranges belong generally to the igneous and palaeozoic formations. Granitic, trap, basalt, hornblende, and other eruptive and metamorphic rocks occur very widely, with slates, limestone, sandstone, &c. Gold is found in the sands of several of the rivers which flow from the Cascade Mountains to the Pacific; and it is said to have been also found in various places east of that range. Other minerals, especially iron, lead, and tin are also said to occur, but none of them have, we believe, been worked. We have not heard that coal has been found, though it is known to exist in Washington. Saline springs occur in the middle section of the Territory, and near its south-eastern corner occur several soda and magnesia springs.

Climate, Productions, &c.—The climate is very varied in the different sections of the Territory. Along the Pacific, and generally west of the Cascade range, it is mild and genial during the summer months, and occasionally severe in winter, while in the middle section the changes of temperature are much greater, and the winter much colder; but the air is more bracing, and the change of seasons is more marked. The climate in the north-eastern coast, it is said that no dew falls in this section. In the vicinity of the Rocky Mountains the changes of temperature are extremely great and rapid. In the south-eastern part of the territory along the line of the great emigration route, the climate is very variable, but rain seldom falls, and there is little snow.

Wheat is the principal grain crop; but a considerable quantity of oats is also grown. Maize is cultivated, but not to any great extent. The other grains are scarcely cultivated at all. Potatoes are grown in the vicinity of the Columbia and Siskiyou rivers. The fruit crops are raised. Small quantities of tobacco, flax, &c., are grown. Most of the European fruits flourish in the valleys of the Columbia, Willamette, &c. At present however the chief dependence of the settlers is perhaps upon the rearing of cattle and sheep, which are usually of the finest quality, and on the excellent pastures. Horses, horned cattle, sheep, and swine are already very numerous; and butter, cheese, and wool receive much attention from the agriculturists.

Oregon presents a great variety of land, but there is no deer, elk, antelope, or other game are still very abundant. Vast quantities of aquatic birds frequent the rivers in the spring and autumn. Along the coast whales are found; and edible fish are extremely abundant both in the rivers and the sea. The river4 swarms with fish, which form the chief food of the Indians. The principal fish taken are salmon, sturgeon, cod, ray, carp, smelt, and innumerable other small fish, with crabs, oysters, mussels, and other shell-fish.

At present the wood and lumber industry is chiefly confined to the production of the articles required in a very thinly peopled agricultural country, and those connected with the shipping trade. The commerce of Oregon is not unimportant, a considerable coasting trade being carried on with California; the exports consist of large quantities of lumber, boards, flour, and provisions generally. There is also a good deal of trade carried on with New York, Boston, &c. The direct foreign trade is of little consequence.

Divisions. The Territory of Oregon is divided into ten counties. Salem is the political capital. All the towns are as yet but small; we notice some of the principal places; the population is that of 1850;—

Salem, the capital, stands on the right bank of the Willamette; it has a small population, and little trade, but contains the state buildings, &c.

Astoria, on the Columbia, 8 miles from its mouth, population 235, is one of the oldest American trading places in Oregon; however it is now but a small settlement, but its present increase is very slow. Milton City, Washington county, population 692, is one of the rising towns of Oregon. Oregon City, on the right bank of the Willamette River, 36 miles N.E. from Salem, population 692, is the chief town on the left side of the Willamette River, and a flourishing district in Oregon. The city possesses a great amount of water power, and appears likely to become a place of considerable importance. Portland, on the left bank of the Willamette, above its confluence with the Columbia, 47 miles N. by E. from Salem, population 891, is also a busy and flourishing place, being the port of entry of an extensive and rich country.

The constitution was enacted by Congress in 1848; by it the right of voting is vested in every white male inhabitant of Oregon, 21 years of age, and a citizen of the United States, or who shall in the usual manner declare his desire to become one. The legislature consists of a council of 9 members, elected for three years; and a house of representa

3  Q 2
ORTHAGORISCUS, a genus of Plectognathi fishes, belonging to the family Gymnotodontidae. On account of their round form the species are called Sun-Fishes. The genus has the following characters:—Jaws undivided, forming a cutting edge without teeth; mouth in a horizontal line, without spines; tail short and very high vertically; rays of the dorsal and anal fins long and pointed, both united at the caudal fin at the base. Two species of this curious genus have been described:—

O. mola, the short Sun-Fish, the Molebath, although only occasionally seen, has been taken around all the shores of Great Britain. When observed in our seas they have generally appeared as though they were dead or dying, and floating to the surface, fish in some distance, for a long time. The original name was derived from Colonel By, an officer of the Royal Engineers, to whom the British government in 1827 commissioned superintend the construction of the Rideau Canal. Byers in law was constituted a city, and the name was changed to Ottawa in 1826. Disagreement having arisen between the inhabitants of Canada West and Canada East respecting the seat of the Provincial Government, the matter was referred to the decision of Queen Victoria, who is stated to have selected Ottawa as the capital of the United Province of Canada. The situation is central for the whole of Canada, and has communication by river, canal, or railway, eastwards with Montreal and Quebec, and westwards with the Detroit River, through Kingston, Toronto, Hamilton, and Chatham.

Ottawa is situated at the entrance of the Rideau River into the Ottawa, 87 miles W. from the confluence of the Ottawa with the St. Lawrence. At the western extremity of the city are the celebrated Cataracts, unsurpassed in America except by the Falls of Niagara. The city is in Canada West, but a suspension bridge erected by the Provincial Government just below the Chaudiere Falls spans the foaming mass of water, and unites Canada West with Canada East. The Rideau Canal divides the city into Upper Town and Lower Town, entering the Ottawa by eight magnificent stone locks: and a massive bridge of cut stone, erected by the Royal Engineers and Tories, crosses the Rideau, and separates them from the Ottawa, one of the two latter falls, by which the Rideau River pours itself into the Ottawa. The water-power for driving mills or machinery is immense on both sides of the Ottawa, and manufactures of various kinds have already been established.

The city is well laid out, the streets wide and regular, the houses mostly of stone, and the principal quarters are lighted with gas. There are already several good hotels. The population now exceeds 10,000. The principal industries are flour and biscuit, the produce of which is sent chiefly to the north and west. The value of this property of 1855 was $3,000,000.

OUDE, according to the Manners and Customs of Hindustan, is bounded S. by Allahabad, N. by Nepaul, E. by Bahar, and W. by Delih. Its greatest length south-south-east to north-north-west is about 200 miles; its greatest breadth east by north west by south is about 150 miles. The area is estimated

484
at 35,000 square miles. The population is estimated at 5,000,000.

Oude was formerly a souabh, or subordinate government, of the Mogul’s dominions. By various treaties between successive victors and the East India Company, Oude became one of the dependencies, stated in 1799 as a British possession with some nominal political control. In 1819 the reigning prince renounced his nominal allegiance to the Mogul, and assumed the title of King. On the 7th of February, 1856, the Marquis of Dalhousie, governor-general, announced by proclamation, that the British government had obtained the annexation of the kingdom of Oude to the British possessions in India. The King of Oude was granted an annual pension of twelve thousands of rupees (120,000/). Oude forms a portion of the plain of the Ganges. The general character of the country, with the capital city, Lucknow, are noticed under HINDUSTAN.

OUDINOT, CHARLES NICOLAS, DUKE OF REGGIO, Marshal of France, and Grand Officer of the Legion of Honour, was born on the 2nd (some biographers state the 25th) of April, 1767, at Bar-sur-Oise. Having chosen the career of a soldier, in opposition to his father’s wishes, he joined the regiment of Medec in 1783; but parental influence induced him to withdraw from the army four years after his entry. Twenty years later, the Revolution revived his martial spirit, and offering himself as a volunteer in 1791, his former service at once procured him a battalion. In September 1792 Oudinot defended the fort of Bisach against the Prussians, whom he repulsed with great loss. He was soon after appointed by the Convention to the command of the regiment of Picardy, left vacant by its former colonel, whom the Jacobins expected of the day had induced to emigrate. At daybreak on the 3rd of June, 1794, being still at a distant outpost, the Austrians, on great numbers upon his regiment; but he held his ground for ten hours against a corps estimated at 10,000 strong. Surrounded by the enemy’s entire cavalry, he formed his men into a square, repulsed every charge of their cuirassiers, and, spiriting himself, opened a passage through them with fixed bayonets, he effected his junction with the main army, his lines never once having been broken. Instantly raised to a brigade for this intrepid conduct, he was sent to besiege Trévoux, and on the 7th of August 1794, capitulating a town, he led the advance of the army of the Rhone, and was ordered to join the army of the Rhine-et-Moselle, which he did on the 14th of September. During a desperate night-attack, October 14, 1795, he was disabled by five sabre-cuts; and having fainted from the loss of blood, was taken prisoner by the Austrians. Released by exchange a few months later, he joined Moreau’s army in 1796, distinguished himself at the battles of Nordlingen and Donauwurth, captured several fortresses on the Danube, and was again most severely wounded at Ingolstadt. On the death of Duroc, 1797, he was appointed to the command of Conde before Constance, and penetrated into the town, in spite of a second corps of Austrians by which it was defended.

Austria was created a general of division, April 19, 1799; and on the 4th of June contributed effectually to the great victory of Zurich. Being subsequently appointed head of the staff in Massena’s army, he shared with that commander the dangers and sufferings of the siege of Genoa. Twice during the siege he successfully passed through the English blockading fleet, bearing with him Massena’s despatches to Suchet. In 1800, as head of the staff under Brune, he obtained fresh honours at the battle of Pozzolo and the passage of the Minio. The First Consul was so highly satisfied with his efficient services, that he presented him with a sword of honour, to which he added one of the pieces of cannon captured from the enemy by Oudinot himself. At the opening of the campaign of 1805 Napoleon formed a picked corps of grenadiers, which the command of which he intrusted to Oudinot, presenting him at the same time with the grand cordon of the Legion of Honour. At the head of his grenadiers he was the first to enter Vienna; he crossed the bridge over the Danube, though undermined and defiled, which became the passage of the Austrian common. General Oudinot was likewise present at Austerlitz.

The following year he took possession of the counties of Neufchâtel and Valengé, relinquished by Prussia; and during his government conducted the liberties and rights of his subjects. Before he left his office, the burghers of Neufchâtel eviscerated their esteem by a public address and the present of a sword. After the battle of Jena, October 14, 1806, he marched into Poland, and gained the victory of Oströmla, February 6, 1807. The Emperor Napoleon now made him a count, to which he annexed a dotation of a million of francs. But the 14th of June 1807, the morning of Friedland, was the most signal of his life. On the famous ground, with his single corps, he checked for many hours the pass of the places by which the Austrians, after the sacrifice of half his men, enabled Napoleon to come up in one of his greatest battles. Meeting the general after the action, Napoleon said to him, with great emotion, you have done wonders but wherever you are my only fear is for yourself. This incident has since afforded a subject for one of Horace Vernet’s best pictures.

In the memorable campaign of 1809 the reputation of Oudinot was fully sustained; for after the death of Marshal Lannes, at Essling, the second corps, formerly commanded by him, was conferred upon Oudinot in these flattering terms — Given to you, as a general, tried in a hundred fights, in which equal skill and intrepidity have been displayed. After the battle of Wagram, Oudinot received the marshal’s baton, with the title of Duke of Reggio, and a pension of 100,000 francs. In 1810, Louis Bonaparte, tired of submitting to the dictation of his imperial brother, threw the whole of the eastern empire, and clandestinely left Holland. Upon this defection Marshal Oudinot was ordered to take military possession of the country; he fixed his headquarters accordingly at Amsterdam. In this government he continued nearly two years, exhibiting great capacity and tact, and adding to the credit of the Dutch people by his integrity and conciliatory behaviour.

Throughout the whole of the subsequent campaigns of 1812, 1813, and 1816, the name of Marshal Oudinot re-appears with the undiminished honour, as one of the best-trained and most efficient of the imperial band of generals. After the first incitement he submitted to the restored Bourbons, stedfastly adhered to their cause during the Hundred Days, and was loaded with favours by Louis XVIII. and Charles X. He was one of the prominent figures in Angoulême in his expedition for the re-establishment of the King of Spain. He was appointed governor of the Invalies in 1842, and died at Paris, September 27, 1847, in his eighty-second year, having been upwards of sixty-four years in the French army.

The marshal’s eldest son, Nicholas-Charles-Victor, the present Duke of Reggio, commanded the French army sent in 1840 to support the authority of the present pope in the Roman states. His younger son, an officer of great promise, fell into an ambush in the late wars in Africa, and was killed by the Arabs, June 26, 1835.

OUTLAWRY. Outlawry, in civil suits, was of two kinds, that on mesne process, and that on final process. The former was an action brought by a plaintiff against a defendant who could not be served with a writ, and it was consequently always reversed on application to the Court, and the defendant appearing to the action. A simple method of giving a most effective judgment, enabling a plaintiff to obtain judgment by default when the defendant does not appear, having been provided by the Common Law Procedure Act, 1839, outlawry on mesne process is by that statute abolished. Outlawry on final process may still be obtained against a judgment debtor, but there are so many other means of stripping him of all his property, that this mode of proceeding is rarely resorted to in practice.

OBEZ (Gray), a sub-tribe of the tribe Boreas and family Borelidae. It includes the common Sheep and allied species. The following is Dr. J. E. Gray’s definition of this family:—

Forehead flat or concave. The horns are more or less spiral, wider than deep at the base, and slightly annulated in front. The females are often hornless. The skull is small, very deep, and cylindrical in section, and shows no significant lobes to the grinders. The hoofs are triangular, and being shallow behind, they have distinct interdigital fossae. Males emitting no bellow.

The genera included in this family are:

1. Ovs. Crumen distinct. Tail elongated. Skin covered with wool or adpressed hair.
2. Caprina. Crumen distinct. Tail very short. Skin covered with thick hair, covering the wool.

Ovis Arsia, the Common Sheep, is subject to great variety, and many of its forms have been raised to the rank of species. Dr. Gray, in the 'British Museum Catalogue,' enumerates no less than 33 varieties of this species.

In the article Ssheep the subject is treated chiefly with reference to farming and grazing. We here present a few of the varieties which are more interesting to the zoologist. The Sheep is one of those animals which man has domesticated, and which, like the horse, dog, cat, pig, and ox, is subject to the greatest possible variety. These varieties have been often described as species; but the most distinguished zoologists of the present day regard all the forms of Ovis as belonging to the species Ovis Arsia.

The following is a list of the varieties from the 'British Museum Catalogue':

1. The Spanish Sheep. It is the Ovis Hispanicus of Linn.;
called also the Merino Sheep and the British Middle-Wooled Sheep.

2. The Common Sheep (Ovis rustica, Linn.; O. Gallicus, Deim.; O. brachyurus, Pallas; O. leptura, Schreb.); the Hornless Sheep (O. Anglicana, Linn.). Of this variety there are numerous forms, such as the Muga Sheep and Shetland Sheep, the Southdown Sheep, the Old Lincoln Sheep, the Romney Marsh Sheep, the Cobwold Sheep, the New Leicester Sheep, the Cheviot Sheep, the Old Teeswater Sheep, the Improved Teeswater Sheep, the Dumpy Sheep, the Zeland and Otway Sheep, the Welsh Mountain Sheep, the Soft-Wooled Sheep of Wales, the Wicklow Mountain Sheep, the Kerry Sheep, the Exmoor Sheep, the Black-Faced Sheep, the Black-Faced Heath-Sheep, and the Bass or Roohan (Ovis Foul, Blyth).

3. The Barwall Sheep, Ovis (Arsia) Bawrul, Hodgson; Ovis Barual, Hodgson; O. Amonoides, var. 1, Gray. It inhabits Nepal.

4. The Hunsia Sheep (Ovis Hunsia, Hodg.) The Hunsia or Black-Faced Sheep of Tibet. Also a native of Nepal.

5. The Cago (Ovis Cagia, Hodg.) The Kago, or Tame Sheep of Cabul region; the Cago Sheep of Gray. A native of Nepal.

7. The Curumbur Sheep of Mysoore.

8. The Sheep called Garah in India.

9. The Dukhan (Deccan) Sheep.

10. The West-Indias Sheep.

11. The Brazilian Sheep.

12. The Demerara Sheep.

16. The Guinea Sheep (Beller et Brebia des Indes, Buffon; O. A. Guineensis, Schreb.).

17. The Movran de la Chine, Buffon.

18. The Shyambular Sheep of Mysoore.

19. The Sheep of Zeyla, of Buckingham.

20. The Fantastic Sheep, of Bennett, from Tripoli.

25. The Zenn or Goitred Sheep (O. A. Zaltinum, H. Smith).

26. The Isalas (Isalas probostum, Ogilby; O. Salan, Sundevall).

27. The Cretan Sheep (O. Strepecarios, Ray; O. A. Strepecarios, Schreb. ; O. Creteos, Jous.; Capra Strepecarios, Brisson; Strepecarios Cretica, Beach; Beller et Brebia de Valachie, Buffon; Zachel of the Austrians; Wallachian Sheep of Bichtig).

28. The Long-Tailed Sheep of Russia (O. longicanecus, Brisson; O. Dolichura seu Proctoriaca, Pallas).

29. The Broad-Tailed Sheep (O. latiacaudas, Erx, Geoff.; Mem. Egypt; Lesson; Comp. Buffon; x. 321; O. latiacauda platyeroga s. Arabico, Linn.; O. Turcica, Charle; O. acauda obsca, Lindeli). It is a native of Barbary. There are several forms of this variety, of which the following are most prominent:—The Fat-Bumped Sheep (O. Strepecarios, Pallas; the forward Sheep of Bewick); the Persian Sheep (O. A. acauda, Geoff.); the Fat-Tailed Sheep (O. A. macacous, Schreb.); the Aera Fiyi, or Abyssinian Sheep; the

Bucharian Sheep (O. Bucharica, Pallas); the Tibetan Sheep (O. Tibetanus, Fischer); the Cape Sheep (O. Caprini, Erxleben); the Sheep of Belkah.

30. The Many-Horned Sheep (O. polyoxus, Linn.). It is called the Four-Horned Ram, and the Dumba Sheep.

31. The Puchis, or Hindustan Dumba (O. puchis, Hodgson).

32. The Short-Tailed Sheep (O. brachyurus bolealis, Pallas). It is a native of Northern Russia.

33. The Sheep of Tartary. They are said to eat bones like a dog.

The genus Caprae embraces the following species:

The Capra Ammon of Linnaeus, the Capra Murem of Brandt. It is a native of Armenia.

C. Murem, the Mouillon. This animal has a multitude of synonyms. It is the Capra Ammon of Linnaeus, and the Ovis Murion of Brandt. It is the Wild Sheep and Siberian Goat of Pennant. It is found in Cypress, Cadiia, and Cordia. For figure of Mouvion, see Suckir, p. 355.

C. Ammonorum, A. Trexelus, the Aouda of the Moors of Barbary and the Kebsh of the Albanian, is a native of North Africa. For figure, see Gogt, where it is named Jucrat.

C. Caspida, the Taye or Big Horn. It is the Ovis Montanus of Geoffroy; and a variety, the O. California, of Douglas. Dr. Gray says it is probably the same as the Ammon of Northern Siberia.

There is only one species of Pavoite, the P. Northor, the Naboer Nervate, or Sna. It is a native of Nepal.

C. Argalis, the Argali. It is the Ovis Argali of Pallas, and often confused with the former. It is a native of Siberia. Dr. Gray says of this species:—The Nyota or Rumbora, or Wild Sheep, seldom or never cross the Hemachal, the Indian side of which range is the special habitat of the Naoro, while to the north and west beyond Thibet our animal is replaced by other species, so that Thibet may be considered as the special habitat of one species (Ovis Amonoides), and the plateaux north of Thibet as far as the Altai of another (Ovis Ammon), cited as types of the true ovine form; and it may be added, that the six sorts of tame sheep of Thibet and the Sub-Himalayas
all without exception exhibit the essential characters of that form.

There are several species that may be confounded under this head: the Siberian Argali is found in the most northern part of that country, and it is probably different from the Himalayan animal; but I have not been able to discover any difference between the specimens received from Mr. Hodgson and those which were sent from Siberia by the Russian naturalist."

OVER. [CHESHIRE.]

OVERSEER. The duties of overseers have by recent statutes been extended and modified in various matters of detail; but the outline of their duties given under Overseers, vol. xvii, p. 70, is still sufficiently accurate, no alterations being of sufficient moment to call for comment.

OVERTON. [FLINTSHIRE.]

Paige, born July 24, 1822, in the city of Hamburg. He was educated at the University of Bonn, and afterwards at the University of Berlin, where he took his degree. His favourite study was geology, which he pursued for some years. In 1840, when Mr. Richardson, at the expense of the British government, was preparing to undertake a journey to Lake Tchad, in Central Africa, Dr. Overweg and Dr. Heinrich Barth were selected to accompany him, in order to make scientific observations. An account of the results of their observations is published under the title of Dr. Overweg's Narrative of an Attack of fever, Sept. 20, 1862, at Madanari, about ten miles east from Kuka, and near the western shore of Lake Tchad.

PACINIAN CORPUSCLES. [TISSUES, ORGANIC, s. 1.]

PAGRUS. [PAECULL.]"
PALABRIS. [LARIBL.] Palaea. [CALTULIB.] Palæmon, Palæmonians. [SHREWS.]

Palm Tree Wine. [BORAG.] Palmblad, Wilhelm Fredrik, a Swedish writer of considerable talent, was born on the 18th of December 1788, at Ljusnedal, near Söderköping, the 11th child of a military commissary, who had procured the situation of Kronofogde, or collector of taxes. The property of the family was confiscated by the government, so that Palmblad, when a student at Upsal, and before attaining his majority, bought, in conjunction with another student, the university printing-office, and with it commenced a series of publications, which had for their object to effect a revolution in Sweden. His first name-day was celebrated by publishing a new periodical by Atterbom and Palmblad, appeared in July 1810, within a month of his taking possession of the printing-office; at Christmas of the next year appeared the first number of the 'Postlak Kalender,' the earliest Swedish annual, and in the beginning of 1813 the first of the 'Svensk Litterat Tidning,' or 'Swedish Literary Gazette.'

The 'Tidning,' which lasted for eleven years—up to 1844—was the most long-lived Swedish literary periodical on record; while the Dans was published in 1824, boasting of one that had outlived a century. It circulation, we are told by Palmblad, was never upwards of 200, and averaged about 150; yet it had a great influence on the cultivation of Swedish literature. It excited the astonishment of the public by the audacity of its articles, and the freshness of its school in literature, which at that time was entirely French in its models and its opinions; and on one occasion the Rector of the University of Upsal summoned Palmblad, as the university had then a Right to influence him, that, if in his periodical contained any more unfavourable criticisms upon the Swedish Academy, his privilege would be withdrawn. The Swedish Academy had been founded in imitation of the French Academy by Gustavus III., who was accustomed to declare that there were more things held in utter abomination—the German language and tobacco. One of the chief objects of the new school, which from the title of its first periodical, the 'Phosphores,' became known by the name of the 'Swedish School,' was to bring the public to some knowledge of the masterpieces of Göthe and Schiller; and in spite of the efforts of the Academy, which in the first instance looked upon the Phosphorists as a body of uncontaminated rebels, the result was general though not local success. After the chief leader of the party, was indeed too fantastic in the character of his own writings to become unconditionally popular; but before the close of his career he was elected a member of the Academy of which he had been a stranger five years before. It is not certain whether the initiative in the new party was taken in the aspect of Swedish literature.

Palmblad, who was writing for the press, continued to contribute to the periodicals that successively arose on the ruins of each other, the 'Journal of the Swedish Literary Union,' the 'Svenska,' 'Skanda,' 'Mimer Frey,' &c., and also pursued an academic career. In 1839 he became 'Docent' or tutor of Swedish history at the university, in 1827 assistant professor of geography and history, and in 1838 professor of Greek. Many of his numerous works are on topics which occupied him as professor; his 'Handbook of Physical and Political Geography' (5 vols. Upsal 1826-37) is of high reputation, and has been translated from Swedish into German. His poetical translations of Sophocles (1841) and of Eschylus (1845) are of some note. When professor of Greek however he often felt an inclination to return to the early armament of writing novels, and his 'Falckenvärd Family,' (2 vols., Örebro, 1844-45), and 'Aurora Köningsmark' (6 vols., Örebro, 1846-51), met with much success, and were translated into German. The work however which has been most universal in its estimate and name is the great 'Biographical Dictionary of Celebrated Swedes,' which he left incomplete at his death, on the 29th of September 1863.

This dictionary, 'Biographiskt Lexicon 56er namnkunniga Svenska Män,' commenced in 1850, was interrupted at Professor Palmblad's death, but is now again in progress. The last volume we have seen is the twenty-second, which brings it as far as the alphabet of the end of the letter W. It embraces the names of the living as well as the dead, and a considerable portion of the information it contains is derived from private communications or from personal observation, and embodied for the first time in its pages. It aspires to give an account of every Swedish name of note, and a list of the works of every Swedish author. The only other biographical dictionary of the same kind as the Swedes possess, is that of Gesellius in three volumes, and a supplement commenced in 1778. But the new work is on a much larger scale in every way than the somewhat meagre compilations of Gesellius. Many of the lives are given at considerable length, several are autobiographies, as the account of Palmblad himself. On the other hand, some of the lives of living persons are little more than a string of dates, with no record of promotions; but such inequalities are of course unavoidable work of the kind. The book, less generally known as 'Palmblad's Biographical Dictionary,' but does not bear his name in the title, and in his life he speaks of himself as only one of the editors, and the author of a considerable number of the lives. It is one of the most indispensable books in a Swedish library, and will, as it comes to be more generally known, do much to spread abroad the knowledge of the illustrious names of Sweden.
adapted to the requirements of the profession in the present century. He retained his position as president till his death, on the 24th of December, 1856, and was succeeded by Dr. Thomas Mayo.

Dr. Paris devoted much attention to the study of the physical sciences, especially chemistry. When in Cornwall he conferred a great benefit on the mining population by suggesting that the bar used for moving portions of rock, should be covered with copper, which prevented the iron of the bar from rusting and which it was found fired against the rock, and which by igniting the gunpowder used for blasting, often produced the most serious ill consequences. In London he became an early member of the Royal Institution, and was the friend and biographer of Sir Humphry Davy. His 'Life' of the great chemist, published posthumously, is considered to be one of the best pictures of his character. He wrote anonymously a little work of great merit, and which has gone through many editions, entitled 'Philosophy in Sport made Science in Earnest.' He was a Fellow of the Royal Society, and a Doctor of Civil Law of the University of Oxford.

PARLIAMENT, IMPERIAL. The alterations which have been made in the law relating to the election of members of Parliament, and the constitution and powers of election committees, have been mentioned under Excerpts, S. 2.

PARONYCHIAE.E. Meiner's name for the family of Plants called by Lindley Knotwort. Brown named this tribe, under Necterum, Nectoreae, which is now most commonly adopted. [Encyclopedia.]
officers of the fleet on that station, and distributed it in manuscript. It was afterwards printed, under the title of "Nautical Astronomy by Night, comprehending Practical Directions for knowing and observing the Principal Fixed Stars of the Northern Hemisphere; to which is prefixed a Short Account of the most interesting Phenomena in the Science of Astronomy; the whole illustrated by several Engravings," 4to.

Lieutenant Parry was desirous of joining the expedition to the river Congo in Africa, but owing to his having been detained at the Bermudas, he did not reach England till the end of 1817, when it was too late. Meantime, in consequence of a report that the Arctic seas were then much less encumbered with ice than usual, the Admiralty had fitted out two expeditions for those seas, one under Captain Buchanan and Lieutenant Ross in the *Italia*, and the other under Commander John Ross for the purpose of exploring Baffin's Bay, and ascertaining the probabilities of a North-West Passage from the Atlantic to the Pacific. Parry having heard of these expeditions, wrote to request employment, observing that he was "ready for hot or cold, Africa or the Arctic regions." When he arrived in London, he was introduced to Mr. Barrow, secretary to the Admiralty, who soon afterwards appointed him to the command of the *Isabella*, under Commander Ross in the *Isabella*. The *Isabella*, followed by the *Alexander*, left the Thames at the end of April 1818. On the 19th of August the two ships were off Smith's Sound at the northern extremity of Baffin's Bay. They then turned southwards, and on the 22nd arrived at the mouth of Jones's Sound, and on the 30th reached the wide opening of Lancaster Sound. The water was deep and free from ice, and on the following day both ships under a press of sail were steered southwards towards the *Isabella*. Parry was full of expectation, as were all the crew on board the Alexander, who, suddenly the Isabella tacked, turned her head eastwards, and rejoined the Alexander. Both vessels then retraced their course, and Lancaster Sound was left behind. Considerable ice had formed in the highland district that was named the Croker Mountains, barring the passage to the westward. The two vessels entered the Thames on their return in November of the same year.

Lieutenant Parry's opinion that there was an open passage Lancaster Sound, and that the Croker Mountains were a mistake, though privately expressed, was soon known at the Admiralty. He had interviews with Mr. Barrow, and was introduced to Lord Melville; and a second expedition for the discovery of a North-West Passage having been re- solved upon, the Hecla and Griper were taken into dock at Deptford to be repaired and strengthened for service in the Arctic seas. Parry was appointed to the command of the *Hecla*, and Lieutenant Ross to the *Griper*; and Lord Melville placed under his orders in the *Griper*. The expedition left the Thames on the 11th of May 1819, and having sailed up the eastern side of Davis' Strait and Baffin's Bay, on the 21st of July they were in 73° 31' N. lat., nearly opposite to the entrance of the Croker Mountains, where they anchored, and lay in the westward intercepting their passage to it. Through these masses however, with excessive labour and frequently exposed to great danger of being crushed, the ships forced their way; and on the 29th of July reached open water on the western side of the ice, passing through eighty miles of it. They entered Lancaster Sound, and sailing westward through the imaginary Croker Mountains, on the 4th of September crossed the meridian of 110° W. long., in 75° 1' N. lat. From this place to their return to London, which was the 26th of September, they received the reward of 5000L, offered by an order in council to such of his Majesty's subjects as might succeed in penetrating thus far to the westward, within the Arctic Circle. Parry gave the name of Barrow's Strait to the continuation of Lancaster Sound; discovered Melville Island, on its northern side, and from its vicinity described the high coast on the southern side, which he named Banks' Land, but which Sir Robert McClure has since ascertained to be the northern side of Banks's Island. He also discovered the Wellington Channel, and penetrated as far as 113° 54' 43" W. long. On the 30th of September, after three days of arduous labour in cutting a channel, with the thermometer nearly at zero, both ships were got safely into their stations on the coast of the Queen's *New* Island. There the ships remained frozen up, with the sun entirely below the horizon from the 11th of November to the 7th of February, and were not released from the ice till the beginning of August 1820. After making several attempts to advance farther westward, they were compelled to return to England, and entered the Thames in November 1820. On the 4th of the same month Lieutenant Parry was promoted to the rank of commander; and several other rewards and honours were conferred upon him. He published his Narrative of a Voyage for the Discovery of a North-West Passage, 4to, 1821, with maps and engravings, which was published by authority of the Lords Commissioners of the Admiralty.

Arrangements were soon afterwards made for another expedition. Captain Parry received a commission, dated December 30, 1820, for the Fury, with Captain G. F. Lyon under his orders in command of the Hecla. This expedition was much less fortunate than the former. It sailed from Plymouth on the 28th of May 1821. After having entered Hudson's Strait, on the 8th of October the ships were frozen in at Winter Island, where they remained till the 2nd of July 1822. They were then released, and sailed northward up Fox Channel. Having discovered the Fury and Hecla, the ships were again frozen in on the 31st of October at the island of Igooolik, on the eastern end of Fury and Hecla Strait. There they remained till the middle of August 1823, when they commenced their voyage homewards, and entered the Thames on the 25th of November. Parry had been promoted to the rank of post-captain, November 6, 1821. His *Narrative of a Second Voyage for the Discovery of a North-West Passage, from the Atlantic to the Pacific, performed in the Years 1822-1825* was published in 1827, and was appointed Acting Hydrographer to the Admiralty.

The Hecla and Fury were soon afterwards retraced for another voyage, this time commanded by Captain Parry and the Fury by Captain H. P. Hopper. They sailed from the Thames on the 8th of May 1824, passed the following winter at Port Bowen in Prince Regent's Inlet, and remained there frozen up from the 28th of September till the 22nd of March next following. The Fury was here wrecked, and the Hecla reached England, with a double ship's company, in the following October. Parry's *Narrative of a Third Voyage for the Discovery of a North-West Passage* was published, in 4to, in 1826.

After his return Captain Parry was appointed Hydrographer to the Admiralty, and continued to perform the duties of the office till the 10th of November 1826. Having then proposed a plan for reaching the North Pole, and obtained sanction for it, he was again appointed to the command of the Hecla for that purpose, and sailed from the Thames on the 3rd of April 1827. The Hecla was secured in Treurenberg Bay, on the north coast of Spitzbergen, on the 27th of July. Parry's plan was to reach the pole by an expedient route which had been prepared for the enterprise, left the ship, and proceeded northward. One boat, with twelve men, was commanded by Captain Parry; the other, with the same number of men, by Lieutenant James C. Ross. The remaining men were employed in the usual manner. This was the discharge of the Hecla. With excessive labour the boats were paddled through the water and dragged over the ice till they attained the latitude of 82° 43', which is the nearest point to the North Pole yet reached. Finding then that a current was taking them southward as fast or faster than they could advance northward, they commenced their return, and reached the Hecla on the 21st of August, after an absence of sixty-one days. The Hecla began her return voyage on the 31st of August, and arrived at London at the end of September. This expedition terminated Parry's arduous labours in the Arctic regions. His *Narrative of an Attempt to reach the North Pole in Boats fitted for the Purpose, and attached to his Majesty's Ship Hecla, in the Year 1827* was published in 1828. He was appointed the deputy hydrographer by authority of the Duke of Clarence, then Lord High Admiral.

Captain Parry resumed his situation as hydrographer; but, as his health suffered considerably from close attention to business, he was appointed to the position of Secretary and Commissioner of the Australian Agricultural Company in New South Wales. Previously however to his departure from England, he received the honour of knighthood from George IV., together with Sir John Franklin, April 8th, 1829; he also was given the degree of Doctor of Laws, conferred on them by the University of Oxford. Sir Edward Parry sailed from the Thames for Australia on the 30th of July, and reached Sydney on the 13th of December. His
residence as commission was at Port Stephens, about 90 miles north from Sydney. He entered the Thames on his return, with his wife and family, in November 1834.

In March 1835 Sir Edward Parry was appointed an Assistant Commissioner of the Province of New Norfolk, but his health giving way under the pressure of work, he resigned the office within a year. In 1837 he was appointed to organise the packet-service between Liverpool and Ireland. Resigning in which in the end of December 1837 he was Comptroller of Steam Machinery for the Royal Navy. He then retired from active service, receiving the appointment of Captain-Superintendent of the Royal Clarence Yard and of the Naval Hospital at Haslar, near Portsmouth. On the resignation of the incumbent, under the provisions of the Organic State of the 26th of February, 1833, which unites Poland to Russia, and for the next sixteen years carried out his plan of subjecting the country, one of the main points in the proposition of the invidious critics, but with his usual good fortune he was enabled to commence a deposition to the emperor in August with the words, "Hungary is at your feet." In 1850 the jubilee of his fiftieth anniversary in the service was celebrated with great rejoicings at Warsaw, and on this occasion the Emperor of Austria and the King of Prussia nominated him a field-marshall in their respective armies. This was the culminating point of Paskevich's long career. When the recent war broke out between Russia and Turkey, the veteran was again summoned to the field, much, it is said, against his will. He planned the campaign against the Turks, which terminated disastrous for the Russians in the repulse of their attack on Silistria, and in that repulse Paskevich himself, had a narrow escape.

From this time he seems never to have thoroughly rallied, and after a long and tedious illness he expired at Warsaw on the 29th of January 1863.

Marashca, a young man, was married to a lady who was a relative of the poet Gribojev, his companion in some of his Persian campaigns, and had by her four children, one of whom, a son, Fedor, is a colonel of the Russian guards, and has also made his appearance as an author. A separate life of the career in France was published by Tolstoy at Paris in 1855.

PASSER. [Sparrow.]

PASSIFLORA. E, Passion-Flowers, a natural order of Hypogynous Exogenous Plants. This order is included by Lindley in his alliance Fidaceae. It is characterised by possessing polypetalous or apetalous corollas; flowers hypogynous imbricated petals; stamens on the stalk of the ovary; simple terminal styles; arillated seeds; and stipitate leaves. The species are herbaceous plants or shrubs, usually climbing, very seldom erect.

Considerable difference of opinion exists among botanists as to the real nature of the floral envelopes of this remarkable order. Jussieu and De Candolle, regarding the parts called petals as a second row of sepal, have made the order classified under Chrysogonum; Pallas, regarding them as a second row of floral envelopes as petals, and made it poly- petalous. Lindley makes the affinities of this order with the genus Passiflora. [Passiflora.] Murensia ocelata, a West Indian Climber, is said to be ananthemis and diaphoretic. Besides the fruit of several species of Passiflora, the fruit of Tussilago farfara, T. tripartita, T. speciosa, and Paropsia adelisa are all of them edible. The species are principally found in South America. There are 10 genera and about 216 species.

PASSION-FLOWERS. [Passiflorae, S. 2.]

PATENT. [Yorkshire.]

PETERSEN. The name of Peterse, to Patents, has been greatly simplified and improved by the statute 15 & 16 Vict. c. 83, the fees payable for a patent have been reduced, and the payment of them spread over several years. One patent now suffices for the United Kingdom; and is no longer scoped as formerly from trifling inaccuracies in the specification, as these may now be disregarded. A Register of Patents has likewise been provided, in which claims, assignments, and licences must be recorded.

PATRICK, JOHN, 3 R 2.
then again assisted by Palm, proceeded to London and Oxford to prosecute his studies. On his return to Germany he was appointed in 1789 professor of the Oriental languages in the University of Jena. Here he occupied himself in illustrating and explaining the Old and New Testaments in a philological-historical manner, which he first developed in his publication, "Die drei Briefe des Paulus," 1791, and "Clavis über den Jésus," 1793, with others. To these succeeded his "Philologisch-kritischer und historischer Commentar über das Neue Testament," which was given to the world in 4 volumes, from 1802 to 1804, which was met with much approval and added much to his reputation. In 1793, on Döderlein’s death, he was created professor of theology, but on account of his health, he removed in 1803 to Würzburg in a similar capacity, where he became also a counsellor of the consistory and government. He retired from the political professorship at Würzburg, he was sent to inspect the state of the schools and churches, in 1806 to Bamberg, in 1809 to Nürnberg, and in 1811 to Ansbach. In this year a call to the chair of exegesis and church history in the University of Heidelberg restored him to his academical life, and to his literary activity. In 1814 the endeavours then being made to give a constitution to his native state of Württemberg excited his attention, and in 1816 he commenced writing in a popular manner on constitutional and political questions, on his experience in dealing with important subjects, as well as on the influence of the Papist government on the national Roman Catholic Church of Germany, and others, gained great applause. In this he continued to write till 1829. As a theological writer he was deeply affected by the German Reformation, and his object was to defend against a once-sided nationality and a speculative deviation from the original doctrines of Christianity, as from mysticism and Jesuitism. With these ideas he began in 1828 a theological work, "Die drei Bücher der Derkter Danksprüche," 1829 to 1829, and another journal called "Kirchenbeleuchtungen," published in 1827. Among his other numerous writings we may mention 'Memorabilien,' published in parts from 1791 to 1793; "Sammlung der Merkwürdigsten Reisen in fremden Ländern," published in 4 parts, from 1800 to 1802; "Leben Jesu, als Grundlage einer reinen Geschichte des Urchristenthums," 2 vols. 1828; "Aufklärnde Beiträge zur Dogmen-, Kirchen- und Religions-Geschichte," 1830; "Exegetisches Handbuch über die drei Derkter Danksprüche," 2 vols., 1830 to 1833; "Skizzen aus meiner Bildungs- und Lebens-Geschichte, zum Andenken an sein fünfzigjähriges Jubiläum," 1839; and the "Vorlesungen Schelling’s über die "Offenbarung," accompanied with critical remarks. Few men have had a wider influence upon religious opinions in Germany than Paulus, though many of his views have been contested as too rationalistic. In 1844 on account of his great age he was allowed to retire from his situation on a pension, and he died 9th May 1849.

PAUKERISM. [Poor-law, S. 5.]

PECULIAR. The jurisdiction of all Royal and other Peculiars in the probate of Wills and the grant of Administrations has been transferred to the new Court of Probate. [P. 492.]

PECIDELLARIA, the name given by Müller to little pincer-shaped bodies found on the surface of many species of star-fishes and sea-urchins. When seen on the surface of the dried specimens they appear like little cleft spines. In Uroaster rudolphi, according to Dr. Sharp, they cover the surface generally, and are more numerous round the spines. Each one of these little bodies consists of a soft stem, which bears on its summit a little forcerole of calcareous matter. If animal happen to be alive between glass when the animal is alive, it is instantly grasped with considerable force. Those on the body and upper spines differ in shape from those on the spines immediately bordering the auras. When the star-fish is living the blades of the forceroles are in continual activity, but when cut off they seem to lose that power. These bodies have been observed by Sars in Echinus spharos, and he describes three species—

P. tridens, P. tripilus, and P. globifera.

The future of all species of the Echiurndormata under all circumstances, which would not be the case if they were parasitical animals.

3. The structure of the calcareous forceroles and stems to which they are attached, bear structurally a greater resemblance to the spines of the Echinodermata than to other structures.

3. The Pedicellaria have a vital connection with the skin and shell of the Echinus. The stem of the Pedicellaria is attached to a knob of the shell of the Echinus, on which it moves.

4. Sars states that when a single Pedicellaria is irritated, the rest are inclined towards it.

Although Professor E. Forbes states that he was not able to confirm Sars in his observations, in two last points, he is nevertheless inclined to adopt the opinion that they were peculiar organs of the Echinodermata, rather than parasitical animals.

(P. E. Forbes, British Star-Fishes).

PEDILANTHUS, a genus of Plants belonging to the natural order Euphorbiaceae. It has a common slipper-shaped involucre. The male flowers several in the circumference. Pedicel bracteolate, each articulated with a naked anther. Female flowers one in the centre. Calyx wanting; style 1; stigmas 3; capsules 3-loculars.

P. tithymaloides, Jew-Bush, is found in various parts of the West Indies in stony bushy places, near the coast. It is a shrub, throwing out runners, erect, about six feet high, usually with a low spreading branch, and may be hardy in the soft, weak, as thick as the finger; when old cinereous, when young green. The leaves are ovate, obtuse, or acute; coriaceous, entire, alternate, stalked, distichous, when young downy on each side, and vary at the edges, becoming as adult to entire, and more or less toothed, sessile, from 8 to 30. Prematurely set out against the extremities of the branches. Involucre slipper-shaped, bright-red with a green back. The practitioners of Curacao give a decoction of the whole plant, especially of the flowers, as an emmenagogue, and in large doses in some diseases. The root is emetic.

PEEL, SIR ROBERT, the second baronet of the name, was born on the 6th of February, 1778, near Bury in Lancashire, the eldest son and third child of the first Sir Robert Peel, one of the most prosperous and valuable landowners in the Borough of Bury. His Ramsgate was his seat. He was educated at Eton, where he was active and influential, and at Cambridge, where he was graduated B.A. in 1806. Both at school and at the university he was distinguished by his talents, his kindness, and the solid perseverance of his character; and, on quitting the university he took what was then (the modern examination system having been but recently introduced) the unprecedented honour of a double first-class—i.e. of paramount excellence both in classics and in mathematics. He had scarcely left college when, in 1806, at the age of twenty-one he was returned to the House of Commons as member for Caithness. His father had destined him for a political career, and from the time of his first entrance into Parliament he was placed in a position of absolute independence by an allowance out of his father’s income equal in amount to the fortunes of most a nobleman.

On entering Parliament Mr. Peel attached himself to the Tory party, to which his father already belonged. Peel was a very close friend of Lord Brougham, and Caithness was his most powerful conduit; while on the Whig benches sat Sheridan, Tierney, Whithread, Horner, Brougham, Romilly, and Sir Frances Burdett. The elder Peel had made no secret of the great expectations he entertained of his son’s success in Parliament; and many of young man’s first steps in the walk of life for which he had been cosily trained, were looked at with much interest and with some jealousy. But Mr. Peel was prudent, and was in no haste to make a measure. "Time is money," and he was笃信 of his character. His first speech of any length was in January, 1810, when he seconded the address at the opening of the session. His subsequent votes and speeches gained him the reputation of a steady and able young man, from whom much might be expected; and this, coupled with his youth, so far as he possessed as the son of a man of so much commercial influence, led to his appointment, in 1811, to the office of under-secretary for the colonies. It was the time of the Peninsular war, and the struggle against the Napoleonic power was formed a part; and as purely colonial questions were of comparatively small importance in the midst of events of so engaging a nature, Mr. Peel had not many opportunities of displaying his powers in his first office, whether as an administrator, as a member of the legislative council, or as a member of the cabinet, he never brought him a clear accession of parliamentary reputation.

The assassination of Mr. Percival on the 11th of May, 1819, occasioned the formation of a new Tory ministry.
The Earl of Liverpool became premier with Lord Castle-
reagh as foreign secretary, Lord Sidmouth as home secretary, 
Lord Eldon as chancellor, and others of the seniors of the 
same party in other places of the cabinet; while among the 
ministers out of the cabinet were Viscount Palmerston, 
secretary at war, the Duke of Richmond as lord-lieutenant 
of Ireland, and Mr. Peel as chief secretary for Ireland. 
The post accepted by Mr. Peel in this ministry, stationing him 
as it did in the midst of the tempestuous sea of Irish politics, 
was far from a pleasant one. How he had a share in the 
union of 1800 had not yet subsided; the agitation for 
Catholic emancipation was fiercer than ever; and Mr. 
O'Connell had just become the leader of the Irish people, 
and agitating out of his heart to drive them to that full 
force of the stormy period. The young secretary for Ireland 
was identified with the anti-Catholic policy of the existing 
ministry; he was nick-named 'Orange-Peel'; and Mr. 
O'Connell seemed from the first to conceive an implacable 
hatred to him personally. After various manifestations of 
this animosity, Mr. O'Connell in May, 1815, attacked him 
in one of his public speeches in terms so directly insulting 
that a challenge was the consequence. Some delay however 
having occurred in settling the preliminaries, the duel was 
prevented. The angry feeling thus attributed by one party 
evident afterwards was that it was at that time that, though 
Mr. Peel opposed the claims of Roman Catholic emancipation, 
and backed the ministry with which he was connected 
throughout the whole of his tenure of office, the Irish 
government of Ireland were by no means those of the 
extreme Orange party. From his first entrance," says one 
of his biographers, "upon the tumultuous arena of Irish 
politics to the end of his life, he would, if he could, have 
quieted the flames; and even when, in the storm, he 
amid their fires, in the cooler element of practical and 
secular education; but this was far beyond his power. His 
encouragement of schools, where the strife of religious proselytism 
might be merged in the soberer pursuits of ordinary mental 
culture, was not only an indistinguishable one, and to 
infidelity by the other; and by the diligence alone 
with which he sought to remedy the multifaceted abuses 
and total want of order which existed in the details of his own 
office, did he discern in Ireland with either the care 
else, for his own party he was too temporising, for the 
emancipationists too exacting." To all intents and purposes 
however he acted consistently with his position as Irish 
secretary under the Liverpool administration. Not only did 
he oppose Mr. Grattan's motion for a committee to consider 
the Roman Catholic claims in February, 1813, and again Sir 
Henry Parnell's motion on the same subject in 1815, but 
his speeches on both these occasions were the ablest that he 
had yet delivered, and came as well to the side of 
denunciation. They were closely bounded with the desirables 
under the ground of essential principle, but strongly and skilfully 
laid hold of the points of real practical difficulty. The truth 
is that a mind so thoroughly good, English, and moderate as 
that of Lord Liverpool, who was not charged, in a subordinate capacity, with the management 
of Irish affairs at a time of such heat and frenzy. Accordingly, 
as soon as an opportunity offered, he vacated the Irish secre-
taryship. The war with Napoleon I. was at an end; 
Waterloo had brought peace; Europe had been re-arranged 
by the Treaty of Vienna; and the Liverpool-Casterlreagh 
ministry, with gradually increasing unpopularity, was 
addressing itself to the home-questions the discussion of which 
formed the leading topic of the day. In this way, the state 
was the state of affairs when Mr. Abbott, the Speaker of the 
House of Commons, having retired into the Upper House as 
Lord Colchester, and a vacancy having in consequence 
occurring in the representation of the University of Oxford, 
Mr. Peel was elected his successor (1818). Mr. Canning 
resigned to the honour; but the influence of Lord Eldon, and 
the conviction entertained by the university of the orthodoxy 
of Mr. Peel's views on the Roman Catholic question, deter-
ned him from accepting. He was offered the chancellorship of 
Oxford, and the preference; it was a little to the damage of the government, already far 
from firm, resigned his post without accepting another. 
From 1838 till 1823 Mr. Peel had no official connection 
with the Liverpool-Casterlreagh ministry. He continued, 
surely, to be the sincere friend of the party which in 1821, 
consISTed of a remonstration signed of a counter remonstrance. 
In consequence. It was during this period, too, that by the 
lead, he took in the pressing currency questions of the 
day, he laid the foundation of his subsequent fame as a 
financier. He had already shown his sympathy with the 
views of what was then called the Economist party, of which Mr. Horner during his life had been the head, and to 
which the House about this time received a powerful acces-
sion of Mr. David Ricardo; and on the appointment of a 
Committee to consider the question of a resumption of cash payments and other allied ques-
tions, rendered necessary by the commercial disturbances attending the 
transition from a state of war to one of peace, Mr. Peel, then 
only thirty-one years of age, was appointed chairman, having 
avowed himself in his speech in the debate on the 
Barnett, Haukisson, Frederick Robinson, and Sir James Mackin-
tosh. In the proceedings of this committee and the debates 
which arose out of them, Mr. Peel displayed his ability both 
as a speaker and as a man of business; and it was in May 
1819 that, in consideration of the collections of the 
cash-payments, he constituted himself the champion, to use 
his own words, of "the old, the vulgar doctrine, as some 
called it, that the true standard of value consisted in a 
definite quantity of gold bullion." "Every sound writer on 
the subject," he said, "came to the same conclusion, that 
a certain weight of gold bullion, with an impression on it 
denoting it to be of that certain weight, and of a certain 
fineness, constituted the only true, intelligible, and adequate 
standard of value, through the whole range of human 
affairs." The same year took part with the Liverpool government in their opposition to the 
thenthen revived agitation for Parliamentary Reform. He 
approved of the famous "Six Acts;" and—what was long 
ago remembered by the other party to his discredit— 
fixed at all the damage of the new currency. Mr. Peel was 
not called upon to exhibit it by any official connection 
with government, the conduct of the magistracy in the 
called "Manchester massacre" of August 1819. He kept 
aloof however, with studious caution, from the ministerial 
connexion in the case of the Soho rioters, who found, in the 
denial of George III. and the accession of George IV. to 
the throne (January 29, 1830), and which were terminated 
by the queen's death in August, 1821. It was in the midst 
of this storm of ministrational politics that Mr. Peel began 
and married. His wife was Julia, the youngest daughter of 
General Sir John Floyd, Bart. The marriage took place on 
the 8th of June, 1830.

George IV., having retained the Liverpool ministry in 
office, Mr. Peel was induced again to become a member of it. 
In January, 1822, he took office as secretary of state for the 
home department. A further modification of the ministry 
was caused by the suicide, in August, of Lord Castlereagh, 
who was succeeded by Sir Francis Burdett. Till the fatal 
sickness of Lord Liverpool (April, 1827) brought 
up this ministry, Mr. Canning and Mr. Peel continued to be 
the most prominent and active members of it—agreeing 
sufficiently to co-operate, but having at the same time 
some differences on domestic politics. Mr. Peel, who was 
charged with the management of the foreign policy of the country, Mr. Peel was busy with new 
forms of the currency-question peculiar to a time of unusual 
commercial distress and panic. While Mr. Canning was 
unfavourable to a consideration of the Roman Catholic claims, 
Mr. Peel, as before, opposed them, though with a growing 
conviction that the opposition could not be long continued. 
Both remained opposed to parliamentary reform. Prior 
to the time of Lord Liverpool's resignation his ministry 
was threatened by a breach with Mr. Canning. Mr. Peel's 
party who stood opposed to the Roman Catholic claims, 
and of whom Mr. Peel was the active leader; and the more 
liberal party, who, with Canning as their leader, 
were approximating to the Whigs. The question, on 
Lord Liverpool's retirement, was the appointment of a 
imperial and an inestimable man, such as the 
Duke of Wellington, to succeed him, the two parties could 
be held together, or whether a new ministry should be 
constituted. There was a strong feeling that the issue 
was the alternative which actually came to pass. The king, 
though personally hostile to the Roman Catholic claims, 
empowered Mr. Canning to form a ministry in which the Roman 
Catholic question should be an open one, but which should 
include the whole of the present government. The 
operation of the Test and Corporation Act. In this ministry, the 
formation of which was regarded as a new epoch in the political 
history of the country, and was accordingly welcomed by 
many of the leading Whigs, Mr. Canning held the Chancel-
tonship of the Exchequer together with the premier's usual office of First Lord of the Treasury; and the blanks in the administration caused by the secession of Lord Eldon, Mr. Peel, the Duke of Wellington, Lord Melville, and others, were filled up by the selection of men willing to act along with Mr. Canning—among whom was Mr. Robinson (now created Viscount Goderich); Mr. Robert Canning; Mr. John Copley (now Lord Lyndhurst) as Lord Chancellor (April 1827). [CANNING, GEORGE]

On Mr. Canning's death (Aug. 6, 1827), his anomalous ministry was dissolved with dispatch, and now came the Whig of the old school, Mr. Peel, into office, and the Whigs, was continued for a few months by Lord Goderich; but on his resignation, in January 1828, a new ministry was formed of the old Tory construction, with the important and significant exception, that Lord Eldon was not re-instated in the old office of Lord High Chancellor. This was in it. The following was the composition of the cabinet of this memorable administration, which, from the names of its two chiefs, is now usually called the Wellington- Peel Administration:—

First Lord of the Treasury, the Duke of Wellington; Chancellor of the Exchequer, Mr. Goulburn; Lord Chanceller, Lord Lyndhurst; President of the Council, Earl Bathurst; Lord Privy Seal, Lord Ellenborough; Foreign Secretary, Lord Dudley and Ward; Colonial Secretary, Mr. Huskisson; Home Secretary, Secretary of State for the India Office, Mr. Granville; President of the Board of Trade, Mr. Grant; Secretary at War, Lord Palmerston. The ministry was afterwards modified by the secession of Mr. Huskisson. Its great act was the passing of the Bill for the re-establishment of the Catholic Relief Bill in the Commons, as member for the close borough of Westbury. His speech on this occasion was not only powerful at the time, but is interesting now as revealing what was called the cardinal principle of Mr. Peel's career as a statesman. "We are placed," he said, "in a position in which we cannot remain. We cannot continue stationary. There is an evil in divided cabinets and distracted councils which cannot be longer tolerated. . . . Supposing this to be established, and supposing it to be conceded that a united government must be formed, in the next place I say that government must choose one of two courses. They must advance or they must recede. They must grant full political privileges to the Roman Catholics, or they must retract those already given. New light has been broken in upon me. Why do I see a necessity for concession now which was not evident before? The same events, I am told, have happened before, and therefore the same argument ought to follow. Is this the fact? Are events in politics like equal quantities in numbers or mathematics, always the same? Are they, like the great abstract truths of morality, eternal and inviolable in their application? May not the recurrence—the continued recurrence—of the very same facts tend to alter its character, at least its practical results?" Mr. Peel on this occasion spoke out, as a statesman, the general sense of the nation; and the Emancipation Act, after running the gauntlet of the Upper House, was passed—Mr. Peel, as Home Secretary, introduced other measures of importance. Long before the New Metropolitan Police Act, which provided London with its efficient body of 'Peelers,' subject to the Home Office, in lieu of the old 'Charles.' Questions of currency also occupied him during this administration.

Though the Wellington-Peel government had yielded on the Roman Catholic Relief question, they were not prepared to yield on the great constitutional question of Parliamentary Reform. In December 1830, Lord John Russell moved the question of disfranchising the unrepresentable boroughs, and transferring the representation to some of the large commercial towns then unrepresented. Mr. Peel opposed the measure, "because it introduced a principle into the system of representation which the country—Mr. Peel said was the ultra-democratic principle, and with which the aristocratic and monarchical principle could not long co-exist." The death of George IV, however (June 26, 1830), and the ascension of William IV, followed as it was by an immediate dissolution of Parliament, and a general election (not to speak of the concurrent influence of the French Revolution of July), rendered the continued refusal of Parliamentary Reform impossible. After the re-assembly of Parliament on the 2nd of November 1830, the Duke again represented the party in the Commons; but Mr. Peel, whose name was also not, was more guarded. Amidst violent excite-
ment, the ministers resigned; and a Reform ministry—the first Whig ministry since 1807—was constituted the same night. Lord Grey became Lord Chancellor; Lord Palmerston, Foreign Secretary; the Marquis of Lansdowne, President of the Council; Lord John Russell, Paymaster of the Forces; Lord Althorp, Chancellor of the Exchequer; and Mr. Peel was succeeded by Lord Grey in the office of First Lord of the Treasury. In this juncture that the death of Mr. Peel's father raised him to the baronetcy and the estates.

For the first time in his life Sir Robert Peel was now in open opposition. He opposed with great determination the Whig schemes of reform, but in such a manner as to indicate his private conviction, from an observation of public opinion, that some change in the representative system was inevitable. His conduct in fact, during the whole of the session of 1830-1, was calculated to increase that impression. He declined at the last moment to join with the Duke of Wellington in the attempt to form a ministry to supersede that of Earl Grey. The Duke of Wellington withdrew his opposition; on the 4th of June 1833 the Reform Bill passed, and on the 26th of the same month the first reformed Parliament met. Sir Robert Peel was returned for Tamworth, which he continued to represent during the rest of his life.

Acquiescing in the new state of things, and abandoning all idea of abridging the constitutional change which had occurred, it was now Sir Robert's aim to organise, what he called a 'Conservative' party, as distinct either from that of the Whigs, or that of the invertebrate Tories. Supported in his new scheme by the Duke of Wellington, and with the active co-operation of the Duke of Richmond, he took the same shape, he acted as a vigilant, but not factious, critic of the various important measures introduced by the Whigs into the Reformed Parliament; first, under the premiership of Earl Grey; and, next, under that of Lord Melbourne. He gave his support to the Irish Coercion Bill; he advocated the abolition of negro slavery in the colonies, but advised great caution in the practical steps for carrying it into effect; and he acted a cautious part in the debates on the Poor Law Amendment Act of 1834, but, on the whole, approved of that momentous change. These measures were carried while Earl Grey was still premier; but before the prorogation of Parliament in August, 1834, Lord Grey had been succeeded by Lord Melbourne, with Lord Althorp as his Secretary of State for Foreign Affairs. Lord Melbourne, Althorp's father, Earl Spencer, in November 1834, having raised him to the Upper House, the king, to the surprise of all, availed himself of the ministerial difficulty thus occasioned, and availed the Whig Ministers another, and call the Duke of Wellington to his councils. Sir Robert Peel had not expected any such event, was then at Rome with his family. Being sent for, however, he hastened back to London, where he arrived on the 9th of December; the Duke, who had, in the meantime, acted provisionally as minister, immediately consulted with him, and a Conservative Ministry was arranged as follows:—First Lord of the Treasury and Chancellor of the Exchequer, Sir Robert Peel; Lord Chancellor, Lord Lyndhurst; President of the Council, Lord John Russell; Secretary at War, Lord Grey; Secretary at Home, Lord Melbourne; Secretary of State for Foreign Affairs, Lord Althorp; Secretary of State for the Home Department, Lord Grey; Paymaster of the Forces, Sir E. Knatchbull; Secretary at War, Mr. Herries; Secretary for Ireland, Sir Henry HARDING.

Sir Robert Peel's administration was short. It began in December, 1834, and in April 1835 it was at an end. On assuming office, Sir Robert, in a letter to the electors of Tam-
worth, had made a manifesto of the intended policy of his administration, with regard to the Reform Bill. He said, "I will now repeat the declaration which I made when I entered the House of Commons as a member of the Reformed Parliament, that I consider the Reform Bill a final
and irrevocable settlement of a great constitutional question—a settlement which no friend to the peace and welfare of the country could have been insensible to the necessity of. Proceeding on this as a fixed principle, the new ministry was to govern the country in a Conservative spirit, but with a readiness to carry into effect certain minor domestic measures in want of change. The policy of the ministry, however, while it was not satisfactory to the remnant of the old Tories, was certainly not satisfactory to the country at large. The Reform Bill had not, indeed, produced all the results that Sir Robert Peel had anticipated; the expected increased activity of the public spirit had not taken place; the disbandment of the militia had not the popular expectation, and the disappointment had begun to show itself among the Radical party, which cried the Whigs severely and were bent on carrying farther constitutional changes. Still, the reaction against Whig rule was not as great as had been anticipated, and the Whigs were again beaten in the Commons by a majority of seven on a motion by Lord Melbourne for an amendment on the address. Sir Robert's speech on this occasion was extremely able. Singling out the fact that the strength of the opposition to his address was a band of Irish members with the Whigs, he adumbrated in cutting terms on this conjunction, seeing that in point of fact the Irish party and the Radicals had been far more unfriendly to the defunct Whig ministry than he and the Conservatives had been, and seeing also that even now the Whigs did not pledge themselves, any more than he did, to the Ballot, the exclusion of bishops from the House of Lords, the repeal of the Corn Laws, or any other of those measures upon which the Reform Bill had been passed. The amendment was, that a Whig ministry could not really be a whit more innovative than his own would be. The answer to this given at the time, says Mr. Doublayle, was "that the Whigs would be more 'squeezeable' than the Conservatives"; and, accordingly, when the Whig ministry was formed, it was an wonderful patience and wonderful practical talent, till April, he was then defeated by so considerable a majority, in a skillfully framed series of motions of Lord John Russell's, which was on various occasions which were intended. This was no option but to resign (April 8, 1832). Lord Melbourne was again placed at the head of a Whig administration, consisting of nearly the same men who had been in office four months before, the chief exception being that in the interior he had before had to do with the Whigs and Lord Brougham, so that the chancellorship was given not to him but to Lord Cottenham. Lord John Russell became home secretary.

The second Melbourne administration lasted throughout the rest of the reign of William IV. (who died June 20, 1837) and during nearly four years of the reign of Queen Victoria. During these six years (1835-1841) though many questions were agitated, their chief success was in the Municipal Reform Bill, passed during the first year. From 1836 to 1839 they were able to do little, and, robbed of their strength as they were by the growth of the more extreme party and of the party who desired a repeal of the Corn Laws, they were becoming more and more unpopular. At last Sir Robert Peel, whose popularity had been in proportion increasing, and who had in the meantime been acting as a critic of their measures, and husbanding his own strength, opposed their bill for suspending the constitution of the Colony of Jamaica; and the majority for ministers was so small, the numbers being 254 against 280, that the Whigs resigned on the following day (May 7, 1839), and Sir Robert was called upon to form a new ministry. In this he failed, owing to the refusal of the queen to consent to the removal of Lord Melbourne. Finally, on July 3, 1841, the War Office was transferred to the Whig party Sir Robert deemed inconsistent with their holding official place under a Conservative government. The Whigs accordingly resumed office, and kept it for more than two years longer. This government, before it was dissolved by Mr. O'Connell's party and the Anti-Corn Law League on the one hand, and of Sir Robert Peel and his well-drilled Conservatives on the other. A general election in 1841, instead of giving them fresh strength, so increased the force of the opposition that an anti-Corn Law majority of 360 against 209 in the Commons on a motion for an amendment to the address so framed as to involve a vote of want of confidence in the policy of increasing specially their financial policy and their conduct in reference to the Corn Laws (Aug. 27, 1841). Three days afterwards Lord Melbourne and his colleagues resigned, and Sir Robert Peel was once more premier.

The new ministry consisted of the following members:—First Lord of the Treasury, Sir Robert Peel; Lord Chancellor, Lord Lyndhurst; President of the Council, Lord Wharncliffe; First Lord of the Admiralty, Lord Haddington; Lord Privy Seal, the Duke of Buckingham; Home Secretary, Lord Stanley; President of the Board of Trade, Viscount Abercorn; Colonial Secretary, Lord Stanley; President of the India Board, Lord Ellenborough; Secretary at War, Sir Henry Hardinge; President of the Board of Trade, the Earl of Ripon; Chancellor of the Exchequer, Mr. Goulburn; Paymaster-General, Sir Edward Knatchbull. Among the ministers not in the cabinet, was Mr. W. E. Gladstone, as Vice-President of the Board of Trade. At the head of this ministry, and with the command of a working majority of 149 and 2, about a half the members of the House of Commons, entered on the greatest period of his political career. The history of his ministry from August 1841 to July 1846 is full of interest. Having committed himself to no definite line of policy at the opening of his ministry, he added one after another of corn duties over a fixed duty, and such other general avowals, the country, on his accession to office, was left to form its own auguries and anticipations. Nor during the remainder of the session of 1841 would he bring forward any explicit statement of imperial measures, or involve himself to mature them during the prorogation. On the re-assembling of parliament in February 1842, he was prepared with his measures. They were of a bold and comprehensive character. First, in the matter of corn laws, he proposed to substitute (Feb. 9, 1842), according to which the duty on foreign corn, commencing in the case of wheat at 20s. per quarter when wheat was at 50s., should gradually diminish, as the price rose,—becoming, for example, 17s., when wheat was at 55s., 12s. when wheat was at 60s., 8s. when wheat was at 65s., 5s. when wheat was at 70s., and only 1s. when wheat should be at 73s. or upwards. There was a corresponding scale for oats and another for barley. The measure, displacing as it did the scale system, was on various grounds, and Sir Robert himself, because they had declared for a fixed duty, to the Anti-Corn Law League, because they desired a total repeal, and to many of the landed proprietors, because they disliked any stabilization at all. This was, however, rejected. After several motions against it on different principles had been rejected, it became law. Next came the important question of the means of repairing the deficit which had been going on in the revenue, at such a rate that the total for the five years ending April 5, 1842, was 7,022,638l. which began the year 1842-43, it was calculated by anticipation at 2,570,000l. On this head, says Mr. Doublayle, Sir Robert argued that the maximum of indirect taxation was then reached, and that to accumulate the already unbearable load of imposts upon the necessary or even the luxuries of life would be ruinous as well as futile. The conclusion, therefore, was that nothing but a direct tax upon income could be relied upon to fill up the hiatus in the exchequer. Accordingly he submitted a bill imposing a rate of 7s. in the pound on incomes of 100l., and a 1s. in the pound on incomes of 50l. and above; a tax of sevensnave in the pound, or nearly three per cent. This also, in spite of opposition, was carried. Then came the reversion of the tariff, by which the premier abandoned the duties on a great variety of minor foreign commodities, such as drugs and dye-woods; and diminished the prohibitory duties on cattle, sheep, pigs, salted meat, butter, eggs, cheese, and lard. Though the new tariff was also carried, it caused dissension between Sir Robert and many of his colleagues, and the most of the debates on the measures of the debates upon it, it distinctly appeared that he was a convert to the theory of free-trade. "I believe," he said in his speech on the tariff, "that on the general principle of free-trade, there is now no great difference of opinion, and that all agree that by the system of free-trade we shall be in the cheapest market and sell in the dearest." This statement drew rapturous cheers from the economists and
opposition generally; and though Sir Robert went on to say, that he deemed corn and sugar exceptional cases, the ulterior tendency was evident. With the exception of some debates on the poor-law, and some on foreign policy in reference to France, Spain, America, and China, the main bulk of the debates turned on the question of taxation and finance engrossed the parliament of 1842. The most important events of 1843 were extra-parliamentary. The permission of the disruption of the Scottish Established Church in May 1843 has been accounted by some a fortunate consequence of the efforts made in the House, and on the part of the citizens of conservation, and has been attributed to false or insufficient information on the part of the government. The contest with Mr. O'Connell, who was then agitating Ireland to be annexed or bought by France and the organised action of an association which had 'repeal' for its motto, occupied a greater share of the energies of the government. For a time Sir Robert, confident, as it afterwards appeared, that Mr. O'Connell himself did not mean to go beyond a certain length, allowed him to proceed without check; but at length (October 1844) the government took their measures, the Clontarf meeting was forbidden, and Mr. O'Connell, his son John, and seven of their associates, were arrested on charges of conspiracy and sedition, and, being tried, were sentenced to fine and imprisonment. From that moment, although the sentence was reversed on appeal to the House of Lords, Mr. O'Connell was virtually crushed; he was never able again to be what he had been.

Banking. The extraordinary activity in railways, had passed away; and 1845 opened with every outward show of prosperity. The parliamentary session of that year was comparatively easy; the renewal of the income-tax for three years longer, the augmentation of the Exchequer, the grants to supporting six new Irish colleges, open to all sects, were carried by the government; and though the Anti-Corn-Law League, represented in the House by Messrs. Cobden and Bright, were making way, the danger of a general drift towards enacting the Corn Laws was not materially affected. But the events of the long recess of 1846 were of a kind to disturb all existing arrangements and all ordinary calculations. The potato rot, followed as it was by a dreadfully famine, was considered it, and this, it was hoped, would come to some conclusion on the great question which the Anti-Corn-Law League had been maturing. Lord John Russell announced this in his famous letter of the 22nd of November, written from Edinburgh, to the electors of London. Sir Robert Peel lost no time in declaring to his colleagues that the Corn Laws must be totally repealed. In this Lord Stanley and others would not go along with him; and on the 6th of December, Sir Robert advised the queen to take a hand in the matter. Sir Robert joined with Lord John in attempting to form a cabinet, Sir Robert was recalled after a few days, and re-accepted office at the head of his ministry (Lord Stanley seceding) with the avowed intention of repealing the Corn Laws. Accordingly, a meeting of the peers was called on the 12th of December, and he brought out a new tariff, and with it his proposition to modify the action of the sliding-scale for the next three years, and after that period to abolish all duties on corn, except the nominal one of a shilling per quarter. Vehement debates followed, in which Lord Stanley, Lord George Bentinck, and Mr. Disraeli, as the heads of a new Protectionist party, attacked Sir Robert with every weapon of sarcasm and argument. The Duke of Wellington however, and other members of great influence, were among his leaders; and the repeal was carried. Defeated on the Irish coercion Bill, only a few hours after the tariff Bill had passed the Lords, Sir Robert resigned office (June 29, 1846). Before doing so he made a magnanimous declaration to the effect that the merit of the repeal of the Corn Laws was more due to Mr. Cobden than to himself, or to any other man in the House. Never perhaps was a minister followed into his retirement with such general applause as followed Sir Robert. His popularity continued unabated during the next four years. During two of these he lent a general and cordial support to the Whig government of Lord John Russell—voting with them on the question of the Navigation Laws, and supporting their various measures. European revolutionary movements of 1848-49 however, brought in a new set of questions, and Sir Robert disagreed seriously with the foreign policy of Lord Palmerston. Antipathies were general of his speedy return to power when, riding up Constitution-hill on the 29th of June 1850 he was thrown from his horse, and injured so severely that he died on the 2nd of July.

This is not the place for any attempt to appreciate Sir Robert's character as a man and a statesman. Many reviews of his career, some in the form of elaborate biographies, have been published since his death—among which may be mentioned The Political Life of Sir Robert Peel, by Thomas Doubleday, 2 vols., 1856; and M. Guisot's more recent Life of Sir Robert Peel, 2 vols., 1880. Papers referring particularly to his conduct in the Roman Catholic Emancipation movement, and in the Corn Law Repeal movement, have also been published by his literary executor. Those who have been in correspondence with him have agreed in their general estimate of him as a man of high conscientiousness, and of a species of ability peculiarly English and peculiarly fitting him for the work which fell to him—ability not of the speculative or philosophical, but of the practical, deliberate, and considerate order. His political genius consisted in perceiving when the necessity for carrying a great social change arose, and in devising the parliamentary means for carrying it. As the leader of a party, and as a master of the art of parliamentary management, he was probably unrivalled; the House of Commons was his element; and though there have been greater orators there, there have been few speakers combining such dignity, tact and courtesy, with fine powers of eloquence. Apart from that, the eulogy of his technical and practical work, which did not himself practise authorship except in connection with practical politics, were high and scholarly, and more wide in their range than might have been supposed.

Sir Robert left five sons and one daughter, Sir John Peel (born May 4, 1829), formerly secretary of legation in Switzerland, and in 1857 a junior lord of the Admiralty, and who has represented Tamworth in parliament ever since his father's death; Frederick (born 1835) who also sat in parliament for several years; and had been secretary for the colonies from 1851 to 1857, with a short interruption; William (born 1834) a captain in the Royal Navy, who has greatly distinguished himself in the Crimean war and in India; John Floyd (born 1837) an officer in the Scots Fusilier Guards; Arthur Wellingay (born 1838) a captain; two daughters, one married (1841) Viscount Villiers, eldest son of Earl Jersey; the other married (1850) the Honourable Mr. Stonor.

PEERS OF THE REALM. In the case of Lord Lansdowne, who had been a member of the House of Commons from 1835 to 1847, and as a mark of the immensely increased feelings of his natural life, it was held (in the Session of 1855-56), that such a grant did not constitute the grantee a lord of Parliament; in other words, that hereditary peerage alone entitled the holders to a seat in the House of Lords.

PEEL, Sir Robert, 2nd baronet, and 18th of the name, was created a peer of the realm for the British possessions in India, by proclamation of the Governor-General of India, dated June 20, 1853.

PEKTLJITE. [MINERATOLOGY, S.1.]

PELAGONIC ACID. [CHEMISTRY, S.2.]

PELLICO, SILVIO, was born in 1789, at Saluzzo, in Piedmont. His father was Onorato Pellico, of a respectable family, and in good circumstances. His mother was a native of Giovine, Venetia, where she had just married. In addition to that of her husband, was called La Signora Pellico-Tournier. They had six children. Luigi and Gioseffina were the two eldest; Silvio and Rosina, twins, followed; Francesco and Marietta were next in succession; and finally Silvio and Claudia, the youngest. Silvio was the son of their parents. Onorato Pellico, while his children were yet young, having established a manufactory for winding silk at Pinerolo, resided there some time; but removed to Turin, where he was appointed to a situation under the govern-
ment. There Luigi and Silvio were instructed in Latin and Greek, and other branches of education, by Don Manavella, a clergyman. Onorato Pellico, who had a taste for poetry and the drama, wrote scenes and short plays, which were performed by his children and others of a similar age, on a small stage constructed by Luigi afterwards became a dramatic writer as well as Silvio.

Silvio Pellico's twin-sister Rosina, who is described as having been extremely beautiful, was married at the age of eighteen to a cousin by the mother's side, who was prosperous, and the marriage was a happy one. Pellico-Tournier, with her son Silvio, accompanied the bride to the residence of her husband. The mother after a short stay returned home, but Silvio continued to reside with his sister's husband during four years. He tells of his first visit abroad ('The Lute') which was published, and was sent to him by his brother Luigi. The reading of it excited him greatly, and stimulated him to the prosecution of his poetical studies. Meantime his father had obtained a situation under the minister of war at Milan, and had removed to that city with his family. His brother Luigi was secretary to the Marquis Caprara, grand equerry of the kingdom of Italy.

Silvio Pellico returned to France in 1810, and went to Milan to be instructed in the Collegio degli Orfani Militari, an occupation which required two or three hours of the day. The rest of his time was devoted to his poetical studies and to the acquisition of the German and English languages. He became acquainted with Ugo Foscolo, with whom he afterwards corresponded. In 1812, a young lady named Piccardone, who resided at Verona. He was for a time tutor to the son of Count Biche, and afterwards to the two sons of Count Luigi Porro Lambertenghi, in whose mansion he was entertained with the most intellectual men of Italy, and with many distinguished foreigners, among whom he himself mentions Madame de Staël, Schlegel, Davy, Byron, Hobhouse, and Brougham. After the fall of Napoleon I, Onorato Pellico retreated to Italy, and in 1813 moved to Turin, where he again took an office under the government. Silvio Pellico continued to reside at Milan with Count Porro.

Silvio Pellico's first dramatic production was the tragedy of 'L'Amante Veneta,' which was followed by his tragedy of 'Rastacce da Rimini,' founded on well-known passages in the 5th canto of the 'Inferno' of Dante. This tragedy was much admired, was acted with great applause in the principal cities of Italy, and established his reputation as a dramatic poet. Byron translated it into English verse, but did not publish it, and Pellico translated Byron's 'Manfred' into Italian prose. He was desirous of publishing his next tragedy, 'Ennio da Messina;' but so many passages were objected to by the censorship that he sent it to Turin, where it attracted much attention. He afterwards removed to France and returned to Italy, and at last gained the consent of the government to publish it. In 1818 Silvio Pellico was the first man to establish a periodical entitled 'Il Conciliatore,' of which he became the editor. It was a kind of Catholic magazine, and with Manzoni, and similar literary men, were the chief contributors; but it was of too liberal a tendency to be endured by the Austrian government, and was suppressed.

On the 13th of October 1850 Silvio Pellico was arrested, and was confined in the prison of Santa Margherita at Milan. He seems to have become a member of the revolutionary society called Carbonari, but does not say so. He was transferred thence to a prison on the island of San Michele, near Venice; and while there he was tried at Venice, found guilty, and was sentenced to prison for a period of fifteen years of 'carcere duro.' In April 1832 he was removed to the prison of Spielberg, near the city of Brunn, in Moravia. Some of these sent to this prison are condemned to the 'carcere duro' (severe imprisonment), and some to 'carcere durissimo' (very severe imprisonment). Silvio Pellico says:—"Those condemned to 'carcere duro' are obliged to labour, to wear chains on their feet, to sleep on bare boards, and to eat the poorest food. Those condemned to 'carcere durissimo' are chained together; and with a band of iron round the waist, the chain being fastened in the wall, so that they can walk only just by the side of the boards which serve them for a bed. Their food is the poorest of all: they have only bread and salt. Moreover, earlier part of his imprisonment, during about eighteen months, he was treated with indulgence by his jailer, and read the Bible, Homer in Greek, Dante, Petrarch, Shakspere, Byron, Scott, Schiller, Güthe, and other writers, and was allowed paper, pen and ink. His friendly jailer having been removed to another situation, during the whole of the years 1824-25-26-27 his imprisonment was excessively severe, and his health was much injured. His imprisonment was afterwards less stringent, and on the 1st of August 1830 he received the announcement that he was to be set at liberty. This promise was soon afterwards performed, and he returned to his parents at Turin. In 1831 he published the account of his imprisonments, entitled "Le Miei Prigioni," which was very circular, and has been translated into the principal languages of Europe. It is written in a style of great simplicity, with much apparent truthfulness, and is very interesting. In 1832 he published at Turin 'Il Nove Tragedie,' which were 'Gismonda da Mandriva,' 'Leonci des Franchi;' 'Tommaso Moro;' 'Orseolo;' which was his tragedy of 'Tommaso Moro.' His mother died in 1837, his father in 1838, and his brother Luigi in 1841. In 1837 appeared his 'Opere Inedite,' 2 vols. One of his latest works was a treatise in prose, 'Dei Doveri degli Uomini.' ('On the Duties of Men'). During his later years Silvio Pellico was secretary to the Marchesa Barola, and he died at her villa of Moncaglieri, near Turin, January 1, 1854.

PENNACEE, a small natural order of Perigynous Exogenous Plants. The plants are shrubs with unisexual inesepaled flowers. The flowers are apetalous, the ovary composed of four carpels, the calyx tubular. Lindley places this order in his Rhammal alliance, and points out its relations with the Thymelaeae and Anacardiaceae. The species are mostly native of the Cape of Good Hope. A scented sweetish nauseous gum-resin, called Sarcocoll, is produced by various species. This substance contains a peculiar principle called Sarcocollin, which is converted into oxalic acid by the addition of water. It links the family of the Capsidae with the Echinodermata. It includes the genera Polinos, Cucumaria, and Oenus.

Polinos (Forbes) has an irregular ovate body, armed with five rows of distant suckers, those below being always bent; tentacula ten; dental apparatus short, truncate; no gizzard.

P. brevis, of Forbes and Gooden, is the only species. It was discovered in the Shetland seas, adhering to the stems and leaves of the fleshy plant, 'Tetraedra'. It is about half an inch in length, of an ovate form, with both its extremities bent upwards. The body is pinkish-white, with minute papillae. The tentacula are long, pedunculated, and directed downwards. The movement is sluggish in its movements, but moves its tentacula freely. Cucumaria has the body regular, more or less pentagonal, with five longitudinal rows of approximate suckers; ten tentacula; dental apparatus composed of nearly square plates of the species are called Sea-Cucumbers. They are the most typical of the Holothuriaceae, and their popular name is very expressive of their usual form. They have all of them the power of changing their shape, so that sometimes they are very long, and sometimes very short; and usually live among sea-weeds or in mud, and are supposed to seize their prey by their large tentacula. They are found very generally throughout the seas of the globe. The following are the British species described by Professor E. Forbes in his 'History of British Star-Fishes':—

C. frondosa (Holothuria frondosa, Gunner), the Great Sea-Cucumber. It has been principally found off the coast of Scotland.

C. peniculus (Holothuria peniculus, Müller), the Angular Sea-Cucumber. It has been taken on the coasts of Devonshire and Dorsetshire, and is found in the seas of France and Norway.

C. commersoni, Common Sea-Cucumber. Great numbers of these animals have been observed off the coast of Wales, and have been dredged in the north and south of Ireland, by Mr. W. Thompson and Dr. Ball.
C. fastuosa, the Long Sea-Cucumber. This is the longest of all the species in proportion to its thickness.

C. hyalina, the Glassy Sea-Cucumber. It is remarkable for its hyaline glossy appearance. It inhabits the Shetland seas.

C. Drummoidii. This species was named after Dr. Drummoid, who discovered it in Belfast Bay.

C. Hydnanae is named after Mr. Hydman, who dredged it in Belfast Bay. It has been since taken in large numbers off the coast of Ireland.

C. Jucica, the Tangle Sea-Cucumber. It has been found in the Shetland seas.

Octus (Forbes and Goodrich) has the body regular, cylindrical, pentagonal, with five rows of distant suckers on the anterior, and a short ventral dental apparatus very short.

Professor E. Forbes describes two species of this genus, which he calls, on account of its size as compared with the Sea-Cucumber, the Sea-Girkin. The two British species are O. brunnea and O. lophura, distinguished by their colour, the latter being milk-white, the former brown.

PEPSIN, a substance found in the gastric acid of man and the lower animals. If the glandular portion of the stomach is treated with extremely dilute acids a substance is thrown down from the fluid by corrosive sublimate, which Schwann first called Pepsin. Wasmann afterwards obtained peptic in a purer form. He proceeded in the following manner:—The glandular layer in the stomach of the pig, which extends chiefly from the greater curvature towards the lesser, is dissected out from the paunch, cut up, then digested with distilled water at a temperature of from 30° to 35°. After some hours the fluid was poured away, the membrane was again washed in cold water, and then heated in the fluid with acid of dilute acetic acid; and repeatedly washed, till a putrid odour began to be developed. The filtered fluid was transparent, viscid, and without any reaction; it was now precipitated with acetate of lead or corrosive sublimate; the precipitate was carefully washed and decomposed with sulphuric acid, the chloroform is then precipitated by alcohol from the watery solution in white flocks.

The peptic thus obtained, forms, when dry, a yellow, gummy, slightly elastic, sublimate moisture; is white and bulky; it dissolves readily in water, and retains a little free acid so as to redissolve it; it is precipitated by alcohol from its watery solution; mineral acids induce a turbidity in a solution of neutralised peptic, which disappears on the addition of a small excess of the acid; but if there be a considerable excess of the acid, there is a flocculent deposit. It is only imperfectly precipitated by metallic salts, and not at all by ferrocyanide of potassium. It has been asserted that peptic is coagulated by boiling, but Forbes and Goodrich have shown that it is not destroyed thereby, if allowed to cool on its admixture with albumen. This substance possesses the converting power so strongly that, according to Wasmann, a solution containing only 1/60,000th part of this substance digests albumen in six or eight hours. Similar experiments have been made by Peppenham, Valentin, and Elsasser.

C. Schmidt has proposed a new view with regard to the nature of the digestive principle. He regards it as a conjugated acid, whose negative constituent is hydrochloric acid, with Wasmann's non-acid or coagulated peptic, as an adjunct; and assumes that it possesses the property of entering into soluble combinations with albumen, gluten, chondrin, &c. Drawing a parallel to this, it more nearly resembles lipo-sulphuric acid than any other coagulated peptic, and as this becomes disintegrated into dextrin and sulphuric acid, so the peptic-hydrochloric acid becomes separated at 100° into Wasmann's coagulated peptic and hydrochloric acid, and in either case it is equally impossible to reproduce the conjugated acid from its proximate elements after their separation. On bringing the complex acid in contact with an alkali, the adjunct—the substance which has been in combination with that acid as a conjugated acid—is precipitated. Schmidt believes that he has ascertained that an artificial digestive mixture, which has expended its solvent and digestive powers, regains them on the addition of free acid; and that when hydrochloric acid is added, the peptic-hydrochloric acid is expelled from its combinations with albumen, and regains its former properties, while the newly added hydrochloric acid enters into its well-known soluble combinations with albumen, &c. By the repeated addition of hydrochloric acid, a digestive fluid or this peptic-hydrochloric acid might preserve its digestive power for ever, unless the fluid became saturated with the dissolved substances, or the conjugated acid underwent decomposition.

(Lehmann, Physiological Chemistry, translated for the Cavenham Press.)

PEPYS, WILLIAM HASSELDINE, F.R.S., was born in the year 1775, in the city of London, where his father conducted in the Poultry a superior business as a cutler and maker of certain classes of surgical instruments. His early histories in some degree resemble that of a remarkable alchemist, who laboured in the progress of chemistry, and of some other branches of science in this country, as well as with that of the various institutions formed for their advancement. In March 1796 he delivered a lecture before the Royal Society, on the 'Chemical History of the Ancients,' with a view of showing the importance of physical and chemical education by the discussion of philosophical subjects. Of these Mr. Pepys was one. He became a member of the British Chemical Society appointed by the society, and took an active part in the experimental elucidation to the members of facts generally understood, and in the repetition and examination of new discoveries. Mr. Pepys also contributed papers to the same body, which, from the residence or occupation of its members in the city of London, eventually led to the foundation of the London Institution, and, through the British Chemical Society, in part also to the establishment of the Geological Society of London, of all which Mr. Pepys was an early member and office-bearer. His skill and ingenuity in the construction of apparatus proved most important to the society, which was founded in 1818, and through the society established the foundation of our exact knowledge of the chemical changes produced in air by that process; while their preliminary experiments on carbon and carbonic acid, recorded in papers contained in the same collection, formed several points in the chemical history, which, which had remained in doubt or been insufficiently examined. In 1865 Mr. Pepys was elected a Fellow of the Royal Society, in the proceedings of which he took an active part on the committee.

As just intimated, he was one of the earliest promoters of the London Institution for the Advancement of Literature and the Diffusion of Useful Knowledge, which was founded in 1865 and 1866, with the intention of supplying for the City of London advantages corresponding to the services rendered in the west of the metropolis from the establishment of the Royal Institution, a few years before. He is named as one of the managers of the London Institution in the Charter of Incorporation, dated January 21st, 1807, and for many years continued to hold the office of treasurer and secretary. On his retirement, some years after he was elected a councillor, and afterwards a vice-president, which office he continued to hold during the remainder of his life. Under his direction a voltaic battery of 3000 double plates of zinc and copper was constructed for the laboratory, with which Sir Humphry Davy's experiments on the magnetic phenomena produced by electricity were made, with the personal assistance of Mr. Pepys and other friends. In the 'Philosophical Transactions' for 1825 is described another voltaic battery devised by Mr. Pepys, which has undergone electro-magnetic experiments, and constructed for the London Institution, consisting of two plates only, one of copper, the other of zinc, those each fifty feet in length and two in width, coiled around each other. A remarkable experiment repeated by Sir H. Davy with this apparatus is described in a paper by him in the same volume. A similar apparatus was produced, about the same time, but quite independently, by the late Dr. Seebeck, of Berlin.

For about 25 years prior to his decease, the progress of age and infirmity withdrew Mr. Pepys in a great degree from scientific society, but he retained to the last his interest in the progress of science, together with a vivid recollection of the paths which he and his friends and fellow lovers of science took through the chemical arts of Cheshire and the contemporaries of Davy and Wellington. He died at his house in Earl's Terrace, Kensington, London, on the 17th of August 1856, at the age of eighty-one.
PERCH. [Persian; Fish.]

PERCLUSION. [Perkussion.]”

PERRY, John, an eminent physician and pharmacologist, was born in the parish of Shorehit, Lon-
don, on the 22d of May 1804. He received his early education in his native parish, and was distinguished at school for his knowledge of classics. At the age of fourteen he entered St. John's College, Cambridge, for the study of theology, but afterwards practised as a surgeon and apothecary. His master having died, he commenced attending on the practice of the Aldera-
gate-street Dispensary in 1821. At this time this dispensary was conducted from a house on the Bank, but on the latter institutions, the attendance on the practice of which qualified medical students as candidates for the Apothecaries' licence. The physicians and surgeons of the dispensary gave lectures, which were also recognised by the Society of Apothecaries for the purpose of obtaining a dispensary licence. He practised as a surgeon at St. Thomas's Hospital, and in March 1823 obtained his licence to practise from the examiners of the Society of Apothecaries. He was not nineteen years old, and the facility with which he obtained his licence, indicates very plainly how small an amount of education was required for the medical man at this time. He was shortly after appointed apothecary to the Aldersgate-street Dispensary, and thenceforward his name was connected with the falling fortunes of this at one time somewhat celebrated school of medicine.

On his appointment young Pereira at once established himself as a private tutor or ‘grinder’ as teachers of this class are technically called. In this capacity he was very efficient, and his early publications all had reference to the wants of medical students. In 1843 he became one of the officers of the society.

He published an English translation of the Latin Pharmacopoeia of the London College of Physicians. He also published a collection of Latin prescriptions entitled ‘Selecta et Prescripta,’ a large number of which have been printed.

He was also appointed to the City-road, who published a ‘General Table of Atomic Numbers.’ In 1835 he became a member of the Royal College of Surgeons. In 1836 he was appointed lecturer in chemistry at the Aldersgate-street School of the College. He delivered the course of lectures on Materia Medica. These lectures were the foundation of his great work on Materia Medica and his reputation as a pharmacologist. The lectures were first published in the Medical Gazette, and the matter was subsequently re-arranged and published in two volumes in 1839, under the title ‘Elements of Materia Medica and Therapeutics.’

Dr. Pereira's mind was eminently discriminative. While lecturing on Chemistry and Materia Medica in Aldersgate-street he undertook the lecture of the class of students at the City-road, who fitted him for working successfully at the Materia Medica, and he produced a work more scientific and practical than any that had before been devoted to the prolific subject of medicines and their actions. Under the circumstances, this was no easy task, but his position as lecturer at the London Hospital School of Medicine, prepared the way for his appointment as physician to that institution. He accordingly in 1840 obtained the degree of doctor of medicine from the University of Erlangen, and was appointed in the same year assistant physician to the London Hospital. He subsequently submitted to the examination of the College of Physicians, and became a London licentiate of that body. In connection with Materia Medica, Dr. Pereira devoted himself to the Materia Dietetica, and in 1842 he published a treatise on ‘Food and Diet,' which, like his work on Materia Medica, was by far the best that had been published on that subject.

Of the works brought Dr. Pereira into considerable note as a physician, and increasing practice compelled him to give up his various lecturships. In 1851 he was appointed full physician to the London Hospital. His great knowledge of Materia Medica pointed him out as the most fitting person to fill the post of chief physician to the London University, an office which he held till his death.

Although Dr. Pereira occupied himself more with compiling and arranging the information obtained from others than making original contributions to the science, his considerable ability in chemical and physiological research. He published a series of ‘Lectures on Polarised Light,’ and many original papers and observations in the Pharmaceutical and Medical Journals. He took an interest in the formation of the Pharmaceutical Society, and delivered several courses of lectures on Materia Medica in connection with that Society. He was a fellow of the Royal Society and also of the Linnean Society. His death, which occurred in 1853, was sudden, and from the not improbable occurrence to this occurrence he had been to consult Professor Quinquet (of the College of Surgeons, London) on a scientific question, and whilst descending a staircase leading to the Hunterian Museum, made a false step, fell, and ruptured the rectus femoris muscle. In all probability, at the same time some internal injury was sustained by the heart or larger vessels; but as only local inconvenience was experi-
enced, no danger was apprehended; but whilst getting up, he fell upon his right side, and fainted. He died in the region of the heart, when he became fully aware that a speedy termination of his life was at hand, and this impression was verified within twenty minutes after." A bust was erected to his memory in the London Hospital by his friends.

PERCH,

PERICLEAE, a Mineral, occurring crystallised in regular octahedrons. Primary form a cube. Cleavage in three directions parallel to the faces of the cube. Colour obscure green. Hardness equal to felspar. Lustre vitreous. Trans-
lucence. Specific gravity 2.75. It is found in the lava of Vesuvius. Its analysis by Damour gives:

PERISTEDEON, a genus of Fishes belonging to the Acoumopharyngidae with hard cheeks. The body is covered with bony plates, forming a defensive armour. The nasal bone is divided into two parts. The first part is the snout and the second part the nose. The second part is divided into two parts, the first part being the upper nasal and the second part the lower nasal. The second part is divided into two parts, the first part being the upper nasal and the second part the lower nasal.

P. Malabarum, the Mailed Gurnard, was taken, according to Mr. Yarrell, off Plymouth in 1836. It is also a native of the Mediterranean. It is easily known from the other gurnards by its elongated and bifurcated nasal bones. It frequents deep water over rocky grounds, and is said to be dangerous only at the period of spawning. It swims with great rapidity, occasionally breaking its nose against the rocks. It is fished in the Mediterranean, and as an article of food is in greatest estimation.

PERIWINKLE, A Plant. [Viola.]

PERJURY. A summary power of committing persons guilty of perjury is vested in all the courts of the country by the statute 14 and 15 Vict., c. 100. One object of the statute is to give the prosecutor his costs, when the prosecution is directed by the court. It was passed to meet an expected increase of crimes from this nature, from the parties being allowed to give evidence in their own causes.

PEROVSKIT, [Munselly, S. 1.]

PERTH. [Canada S.]

PERTHES, CHRISTOPHER FRIEDRICH, one of the most distinguished booksellers of Germany, was born April 21, 1772, at Rudolfstadt, the capital of the petty German principality, which has since been united to the larger state of Thuringia. He was secretary of the exchequer, who, dying in 1777, left his widow and son unprovided for, except by a pension of twenty-one florins to the widow. The widow sought to maintain herself by going to service as a nurse, while young Perthes was confined to the care of his grandfather. On her death in 1779 he was transferred to his maternal uncle, Friedrich Hebel, also a state official of the Prince of Schwarburg, who as far as he was able instructed the young Perthes, instilled good principles into him, but little of literature. At the age of twelve he was sent to the gymnasiurn of Rudolfstadt, but his previous deficiencies rendered him unable to profit much by the instruction here afforded, a loss which he continued to lament in later life, and which he then made great efforts to repair. While at this seminary however, he was much delighted in reading travels, and they appear to have had much influence in developing a feeling of self-dependence on his own exertions; and another relation, Lieutenant-Colonel Hebel, the superintendent of public buildings, by taking particular notice of him, gave him a liking for natural scenery. A brother of his father's was a bookseller at Gotha, and this seems to have led to the idea of dedicating Perthes to that trade. In 1786, therefore, he was apprenticed to a bookseller in Berlin, where it was his fortune to find a master for him. He was rejected by one because he could not construe one, and by another as too delicate; but one, Bihme, agreed to take him as an apprentice at the end of another year. On September 11, 1797, he entered upon his new occupation. His master was not unkind, but strict; he was employed in the lower and more
irksome duties of his trade: particularly as a collector; his feet were frost-bitten in the winter; he was confined to his room for nine weeks, during which his master's daughter, Frederika, of 12 years of age, attended him, and read to him a translation of Muratorii's 'History of Italy.' He recovered and became fondly attached to his nurse. While serving his apprenticeship his desire for acquiring knowledge was great, but his means were so restricted that he could not continue this pursuit by his own exertions. His mother's pension (about 2L. a-year), a few occasional presents from his uncle Hebel, and two dollars yearly from his master, formed the extent of his funds, and with these he had to supply himself with shoes and clothes. After his discharge as an apprentice he was introduced to a young artist named Nessig, was introduced. This associate became a candidate for the affections of Frederika. The rivalry revealed to Perthes that he was in love, and like a true German, hid in his heart the consciousness of his rival. They agreed to each attempt to gain her, and that the unsuccessful suitor was to submit uncomplainingly to his fate. In 1792, when the French revolution broke out, both uncle and nephew took a great interest in its progress; but Perthes saw and expressed in his letters to his uncle reasons for apprehending danger. His manners appear to have been all his life peculiarly attractive, modest yet firm; and while with Böhme he became acquainted with Góthe, Herder, and Schiller. At the Easter of 1796, Hoffmann, a large publisher in Hamburg, having expressed a wish to see some of Perthes's drawings. His master released him from his apprenticeship, which had yet a year to run, and he departed with Hoffmann to Hamburg. While there, he sedulously attended to his business, he had, however, his relations with his master, a real friend, of his rival, Nessig, who undertook to give a faithful account of Frederika, and the state of her affections. His notions of bookselling appear to have far exceeded those of either of his masters. In 1794 he writes: 'Where will you find a body of men so deficient in the requisites of book selling, and so negligent of the duties of their calling, as the booksellers? Germany is deluged with wretched and abominable publications, and will be delivered from this plague only when the booksellers are put to shame for good.' After a residence of about three years with Hoffmann, during which he had won the esteem of many eminent literary men, and made great efforts to repair his defective education by study and by intercourse with the numerous French emigrants then in Hamburg, and having received a promise of the reversion of his uncle's business in Gotha, for which he was not inclined to wait, he determined to begin business for himself. This he effected on borrowed capital, and with the most zealous and unswerving energy, and in 1801, he opened an office of his own, and received the name of Alfred Perthes. As soon as this was effected, they both offered their professions to Frederika Böhme, who declined to marry either, though she owned that she loved both—a good reason, perhaps, for her resolution. Perthes was in despair. He writes, 'my whole life-long hope was crushed under her cruel foot.' He failed in his business, in hopes of thus overcoming his apprehended ruin—and succeeded. The partnership with Nessig did not last long, as it was found that, though not unsuccessful, the profits were not enough for two; and he now proceeded on his own account. His acquiescence with literary men extended. Fred. H. Jacobi, the Stolbergs, Voss, and Count Reventlow were among them. By Jacobi he was introduced to Claudius, the editor of the "Wandsbecker Botke" (Mes- senger of the German Art). He made an appearance at a short courtship, on August 2nd of that year. She was a delicate retiring woman, possessed of strong religious feelings, and an ardent love for her husband; but his active bustling habits gave her occasional uneasiness, and she would have preferred his being more calm and less worldly. To her gentle remonstrances he replied, "I am persuaded that I am a man born to turn my own wheel, and that of others, with energy." In 1799, with an addition of capital, also borrowed, he entered into partnership with a Bernhard von Gersdorff, a merchant, and the business prospered. By 1806, Perthes had an office of the same name in London, Paris, and a branch in Vienna. When his shop was incorporated in 1810 with the French empire. Still the firm went on, though embarrassed by the Milan and Berlin branches, and the censorship to which the press was subjected. Perthes, in compliance with a correspondence, lamented the apathy of Germany under the French yoke, and when the French re- tired before the Russians in 1813, he took an active part in restoring the old constitution, and became a member of the burgher guard. But the French under Davout and Vandamme almost immediately returned, regained possession of Hamburg, levied enormous contributions, and devastated the town. Perthes had sent his wife and family to Wandsbeck, but he was a marked man, and one of those exempted from the general pardon which was proclaimed. He was forced to wear a blue coat, the badge of a Jew, and was declared a spy. It was now that the calm heroism and devoted attachment of his wife displayed itself. She thanked him from her heart "that your name stands among the ten enemies of the tyrant," and subsequently, though suffering extreme depriva- tion, she never failed to do her utmost to assist her husband in persisting in fulfilling his duty. In 1814 they were enabled to return to Hamburg, where, by the exertions of Besser, they met all their trade obligations, and the business again pro- cured prosperity. In 1821 his excellent wife died, after which he resigned the Hamburg business to his partner, and in 1822 removed to Gotha, where he conducted more largely as a publisher, the works chiefly produced being on theology and history. In theology he published for Neander, Ullman, Tholuck, Bunsen, and many others, who were opponents of the rationalistic opinions; and in history he published the 'General History of the State of Europe,' edited by Heeren and Ubert, to which many of the most eminent writers of German literature contributed. It was also published as 'Abkommande von Gotha.' In all these undertakings he was not only publisher, but a most efficient adviser, and his opinions were highly valued, not only by the contributors, but by men like Niebuhr and Eichendorff. His business was almost as fortunate as his first. Charlotte Becker, a widow, was an excellent mother to his children, and an attentive and affectionate wife to himself. Some few years before his death he resigned the business to his son Justus, who is now (1845-5), and of five, published 1844-5, 500 for printing maps on a large scale forms a part. He retired to the village of Friedrichroda, a few miles from Gotha, where, with a cheerful and tolerant piety which had always characterised him, he awaited his dissolution, which took place on May 16, 1843.

Perthes' correspondence was very extensive, and was both instructive and entertaining. Excellent specimens of it are given in 'F. Perthes Leben. Nach dessen schriftlichen und mündlichen aufgezeichneten,' in 5 vol., published 1845-5, by his son, Clemens Theodor, who is professor of law in the University of Bonn. Besides these, some of his correspondence was published in 1819 in 'Etwas über den Deutschen Adel, in Berlin,' a correspondence with Perthes Fouqué, and a correspondence with 'Berichte zur Gesicht der Deut- lands in den Jahren 1800-1809, aus brieflichen Mittheilungen,' letters between Perthes, Johann von Müller, and others, issued in 1803. His son Clemens, besides the Memoirs of his father, has published a volume in honour of the Revolution. Eine Vorarbeit zum deutschen Staatsrecht,' 1845; and 'Einverleibung Krauskas, und die Schlußace des Wiener Congresses,' 1846. The Memoirs have been trans- lated with some condensation, in 2 vols. 8vo, published in 1856.

PESTALOZZI, JOHANN HEINRICH, was born January 13, 1746, at Zürich, in Switzerland. His father, who was a medical practitioner, died when Pestalozzi was about six years old. But his mother, with the assistance of her relatives, procured him a good education. He studied divinity and afterwards law, but instead of adopting either the clerical or legal profession, turned to farming as a means of support. At the age of twenty-three he married the daughter of a merchant of Zürich, purchased a small landed property which he named Neuhof, and went to reside upon it and cultivate it. The reading of Rousseau's 'Emile' had drawn his attention to the subject of education, and he began in 1770 to carry out his views by turning his farm into a school, and conducted the instruction of his pupils by the example of the industrial pursuits as well as in reading and writing. In this, however, he was little more successful than he had been in his agricultural operations: at the end of two years he was obliged to abandon the enterprise and was invol- ved in debt. In order to relieve himself from his incum- brances, and to procure the means of subsistence, he produced his popular novel of 'Leinhard und Gertrud,' 4 vols., Basel, 1751; in which, under the guise of depicting actual peasant life, he sought to show the neglected condition of
then, and till his death the name of Petrovics, equivalent to
'Petersen,' which showed that he was of Slavonic descent;
the son changed the name to Petofi, which has the same
meaning in the Magyar or Hungarian language. The father
was worthy of note, as showing, in conjunction with some similar
instances, that in a country where the rivalry of different
nationalities has been pushed to a disastrous extreme, the
most vehement defenders of one nationality may be recruited
from the other. Petofi, in his youth, was sent abroad, to which
his father, who, having succeeded in trade, was anxious to see his
son in a profession of some kind, and seems to have been indif-
ferent, whether in divinity, law, or medicine. The youth was
wild and unruly, and extravagantly stage-struck, and was
expelled from the University of Salzburg, to which his father
had sent him, for engaging in some theatrical performances.
Not daring or not wishing to return home, he went to Pesth,
where at the age of fourteen he gained a precarious livelihood
by assisting as a scene-shifter at the theatre, but spent most of his time in the streets. His father came to Pesth
in search of him, took him home by force, and kept him as
a sort of prisoner for about two years, after which he again
sent him to school at Oedenburg.

The first thing that Petofi did on arriving there was to go
to the barracks and enlist as a soldier in an Austrian regiment,
which he understood was to be quartered in the Tyrol, when
he intended to desert, and enjoy a free life among the
mountains. The regiment was sent instead to Croatia, and
in the discharge in that country he fell ill, and was con-
tinued seriously affected so long that the regimental doctor
in 1841 recommended his discharge. Being now of the age
of eighteen he resumed his studies at the college of Paps,
where he was a member of the University of Vienna, and
have since attained to some eminence—Orlay as a painter,
and Jokai as a novelist. At that time Orlay was ambitious of
becoming a poet, Jokai a painter, and Petofi an actor, and
all three failed in their respective ambitions. Petofi, who
left college to continue his studies of law in Pesth, seems
ever to have met with even the most moderate
degree of success, and was soon plunged in the most abject
poverty. He had long been in the habit of composing songs
and poems for his own amusement, and on this occasion
called on one of his old associates, a publisher called
Bajza, the editor of the 'Atheneum,' a popular periodical, mentioning to him that they were the composition of one Petofi, but not mentioning
that Petofi was himself. The poems awakened the attention of
Virovatsky, at that time the managing editor of the 'Debrecin,
who predicted that the author would soon stand high,
and began to exert himself to bring him into notice. Some other
friends procured him literary employment to translate into
Hungarian a novel of G. F. K. James, entitled 'Forest
Sorrows,' and he also translated a number of the works
of pupils and of visitors. Unfortunately dissensions arose
among the teachers, in which Petofi himself became
implicated, and which embittered the latter years of his life.
The number of the pupils actually present at the Institute
came to be a losing concern, and Petofi was again involved
in debt, which the proceeds of the complete edition of his
works ('Petofi's Sämmtliche Werke,' 15 vols., Stuttgart
and Tübingen, 1819-30) hardly sufficed to liquidate. This
event was the result of a subscription got up in 1816 for
the publication of his works, the names of the Emperor of
Russia, the King of Prussia, and the King of Bavaria standing at
the head of the list.

In 1837 Petofi retired from his laborious duties to
Nagymaros, where his grandson resided. Here he wrote his
'Schwanengesang' ('Song of the [Dying] Swan,' 1826;
and 'Meine Lebensschicksale als Vorsteher meiner Erzie-
hungsanstalten in Burgdorf und Ittern.' ('My Life's Fort-
resses as Superintendent of Educational Establishments
at Burgdorf and Yverdon,' 1826). He died February 17,
1837, at Brugg, in the canton of Aargau.
for hostility to the aristocracy, as well as by a warm feeling
of personal independence.

On the 16th of March, it was Petőfi who incited the
students of the university to action by reading aloud
in the yard of the university his poem of 'Tarlapa Magyar' ('Hunga-
rarian, up!') which was received with shouts of applause;
the poem is in manuscript and several copies, being the
first printed in Hungary without passing the censorship;
and at the theatre that evening, after the great
events of the day, it was sung again and again, the whole
assembly 'sing and shout'. The im-
vasion sobh.' ('Now or Never'), and 'Csataidal' ('Battle-
Song'), had a great influence on the popular mind. He
failed however as a candidate for a seat in the National
Assembly for Little Kumania, but seized every opportunity
of denouncing the government and his
low estate. When on the 21st of August 1846, the two parties of the
Moderate and the Extreme Liberals in the National Assembly
came to a conflict on the question, if the words of command
to the Hungarian army should be given in Hungarian, or as
they had always been before, in German, Vörösmarty, who
was one of the deputies, gave his vote in the side of the
Moderates, who, on that occasion, were first brought into
a majority by the party of Kossuth. Petőfi, who, only a few years
ago had denounced the influence of:
the poems to Vörösmarty, "as a sign of love and esteem," on
this occasion wrote a poetical address to him renouncing his
friendship, each stanza concluding with the lines,

'If I do not tear the laurel from thy brow,
Fix thy own hand on it now;'

and in spite of the remonstrances of mutual friends, gave it
to the public in the 'Eletkepek' ('Pictures of Life'), a
periodical he was then publishing in conjunction with Jokai.
Soon after he exchanged the pen for the sword, and joined
the division of the army under the command of General
Bem, who appointed him his aide-de-camp. A dispute with
General Mészáros, who found fault with the poet's inattention
to discipline, induced him to throw up the appointment in
Mátyásmező, and his publishing the mark- ing
the quarrel was between a butcher (the meaning of Mészáros
in Hungarian) and a butcher's boy. The approach of
the Russians led him to take up arms anew; he again became
aide-de-camp to Bem, and he shared the last terrible
campaign of that general in Transylvania. After one of the
most desperate fights of that period he was seen no more, and
it was universally believed that he was one of the slain. His
body however was never found, and in 1855 a report was in
appearance of a Hungarian regiment,
in London, and elsewhere, that Petőfi was still alive and in concealment.
Six additional years have now elapsed without any tidings
being heard of him; his wife has been long re-married, and
there seems to be no possibility that he is still among the
living. In the last poem of the first edition of his works
beginning 'Egy gondolat bán engemét,' he expresses a horror
of dying in bed, and puts up an ardent prayer for death
on the battle-field.

There is a collected edition of the poems of Petőfi up to
1846, in two small volumes, of which a first edition
was published at Pesth in 1847, and a second in 1848. Two
additional volumes, containing his subsequent works, were
seized and suppressed by the Austrian government after the
defeat of the revolution of Hungary. Many of them are to
be found in a volume entitled 'Hungok & multobul' ('Sounds
from the Past'), published at Leipzig in 1851, of which a
German translation by Vási and Benkő, with interesting
notes, appeared at the same time. The title of
'Nationaleider der Magyaren.' As the wonderfully idiom-
alistic elegance of the language is always spoken of as one
of the principal charms of the poems of Petőfi, the foreign
reader can hardly expect to appreciate them with any
approach to the results of a native; but there is a lore as to
information chiefly taken, informs us that in English his
favourite authors were Shakespear, Byron, Moore, and
Dickens; and that he was accustomed to call Dickens, from
the kindliness which his writings tend to inculcate, a "ben-
efactor of mankind." Characteristically enough in a
songwriter, he regarded Béanger as "the world's greatest poet."
His own long poems are very inferior to his short ones; and
in prose he can only be considered to have succeeded in
some measure in a translation of the 'Eletkepek.'

PEVENSEY. [S.]

PHARMACOSIDERITE. [MINERALOGY, S. 1.]

PHASMID. A tribe of Orthopterous Insects, embracing
embracing the Grasshoppers, the Crickets, and the
locusts, from which they are distinguished by the fore-
legs being of the ordinary size, and fitted like the rest for
walking rather than running. From the other Orthoptera
they are distinguished by the hind legs not being saltatorial.
The point of the hind legs is usually concealed in the
Mandibles, from which they are not separated by the
outer edges; the former are of moderate size, an oval subangular in form, with
large globular eyes, in front of which the antennae are placed, which
are variable in form, but ordinarily long, slender, and
composed of a great number of articulations. The occelli are
rudimentary or obsolete. The labrum is deeply notched in
front; the jaws are strong and horny. The dorsal surface in
both sexes consists of nine segments, but only seven are
distinct in the females. All the legs are alike, being long and
slender. The fore wings are of small size, and attached at the posterior
part of the mesothorax. The true wings are very large and
attached to the anterior part of the metathorax. 'As they
far exceed the wing-covers in size, it is essential that provi-
sion should be made for their defence, and that they may be
passed as in the earwig, by the transverse folding of the wing so as
to enable it to be folded beneath the small wing-cover, but
by the front margin of the hind wing being greatly thickened,
serving as a flat plate, beneath which the other part of the
wing is folded against the latter part being often dif-
ferently coloured. Thus in some species the short wing-
covers and the front margin of the wing are pale-green,
whilst the other part of the wing is pink. Many species
possess wing-covers throughout the year, others after
acquiring wings or wing-covers.' (Westwood, 'History of
Insects.')

The odd appearance of these insects have got them for the
name of Walking-Sticks, Staffs, Leaves, Spectres, &c.,
certainly nothing can be imagined more curious than the
forms they assume. In many instances they might be
misled for a portion of the branch of the trees on which they
rest.

RENKITE. [MINERALOGY, S. 1.]

PHENYLE. [CHEMISTRY, S. 1.]

PHILLIPS, RICHARD, F.R.S., some time President of
the Chemical Society of London, first Curator and Chemist of
the Museum of Practical Geology, an eminent mineral-
ologist, and another member of the "Ultimate Chemical Club.
James Phillips, a member of the Society of Friends, who
headed the business of a printer and bookseller in George
Yard, Lombard Street, London. Richard was born in the
year 1786. He was educated as a chemist and druggist, under
William Allen, at the well-known pharmaceutical establish-
ment, Plough-court, Lombard-street, London; but he received
his first instructions in chemistry from Dr. George Fordyce.
Richard Phillips and his older brother William, the
mineralogist, William Allen, Luke Howard, and several
other members of the Society of Friends, and three young
men who were not Quakers, were among the founders, eight
in number, of the Askean Society, already noticed in a pre-
ceding article on Mr. Pepys, who was one of those three.
Richard Phillips was elected a member of the Askean Society
as address president of the Chemical Society in 1866., "we
are indebted for the first correct analyses of the Bath waters,
in the course of which investigation he discovered the cause
of the apparent uncertainty in the indications afforded by the
steam tests for iron, caused by the variations that occur in
their effects, according as carbonate of lime is present or
not." The elaborate paper stating the process and results of
these analyses, was first communicated to the Askean Society.
His labours in mineralogical chemistry were characterised
by great neatness and precision, so that they may indeed be
appealed to at the present time as models of skilful and
exact research. The analyses of the Bath waters were suc-
ceded by the completion of one of the rarest of rare minerals.
In 1832 he discovered that the mineral called uranite was not the hydrated oxide of uranum,
PHI. 503 PHI

as it had been previously supposed to be, but by a hydrated double phosphate of that metal and copper. The presence of phosphoric acid in uric acid had escaped the scrutiny of Berzelius, who was thus as much outdone in this particular matter, owing to the subject of this paper, as Berzelius was when he detected the presence of the same acid in wattlewood, which the great English chemist had overlooked.

The late Dr. Thomas Thomson, Regius Professor of Chemistry in the University of Glasgow, the author of the course of lectures on the History of Chemistry, forming part of the 'National Library,' published in 1831, when reviewing the progress of analytical chemistry in Great Britain, bore the following honourable testimony to the merits of Mr. R. Phillips—a testimony involving also commendation of the work of Paul Hulth, the first chemist of science in this country, which thinking men of all ranks perceive to be of daily augmenting importance to the community:—"Of modern British analytical chemists, says he, in his 'History of Chemistry,' to whom we are indebted for not a few analyses, conducted with great chemical skill, and performed with great accuracy. Unfortunately of late years he has done little, having been withdrawn from science by the necessity of providing a livelihood in this country except by turning one's attention to trade or manufactures."

It was however in the pharmaceutical branch of practical chemistry that Mr. R. Phillips's services were most conspicuous, as may be seen by the several publications of which he was the author. One of them is 'The first edition of the famous "Handbook of the Pharamaceutical Society," which originally appeared in "Blackwood's Magazine," but which has been reprinted two or three times reprinted in a separate form. He afterwards wrote other tales in the pages of that and other periodicals, but none of them we believe were published with his name. In 1850 he published a brief space of time. Phillips died in 1854, and his brother-in-law, Mr. R. Phillips, was the last private of the profession to carry on the business of the late Mr. Phillips. In 1855 he was admitted to the bar at the seat of the Marquis of Ailsbury in Wiltshire, in order to read with Lord F. Bruce, and whilst he was there he was thrown from a horse and seriously hurt. He had perhaps always had a tendency to consumption; it was developed by the hurt, and during his remaining days he worked with the weight of that terrible malady pressing upon him. But he worked steadily on, and was able to secure himself a handsome income, and an honourable position among his literary contemporaries. Writing exclusively in newspapers and periodicals, it was only in the last year or two of his life that Mr. Phillips was at all known by the name of the general public, yet he probably exercised a much more considerable influence on public opinion and public taste than many much better known, as a writer in such papers as the "Times," the "Morning Herald," but he afterwards became one of the chief editors of the literary staff of the 'Times,' and during some years his brilliant criticisms on current literature awarded an agreeable relief among the news and politics of that powerful journal. In the 'Times' his pen was exclusively confined to literary criticism,—at any rate he never wrote "leaders"—and he continued to write its more important reviews down to his death. Two volumes of 'Essays from the 'Times,' by him, were published, though still without his name, in 1858 and 1864. "Locid, picturesque, often eloquent, and sometimes bitterly keen, yet discriminating, and with all the appearance of being scrupulously fair, they will no doubt keep their place as a permanent addition to our store of that class of writing which, in the opinion of many, is the most useful which appeared after the publication of these volumes, are of at least equal merit. Besides his papers in the 'Times,' Mr. Phillips wrote reviews in the 'Literary Gazette,' &c. He also purchased, and for a time edited, the "John Bull" newspaper, but without much pecuniary success. In the formation of the Crystal Palace Company he took an active part; and for a time acted as secretary, and subsequently as "literary director" to the company, and many of the arrangements for the exhibition, he the model of his own, were contributed by Mr. Phillips. The Crystal Palace was likewise the general 1. Guide to the Crystal Palace, and Park; and the 1. Portrait Galleria of the Crystal Palace. He died at Brighton, where he had gone on account of his health, on the 14th of October, 1864, from the rupture of a large vein in the innominate artery, which had been caused by the removal of the artery for which he had been enabled to make a comfortable provision. In 1852 the University of Göttingen conferred on him the honorary degree of LLD.
PHI

PHILLYRINE. [CHEMISTRY, S. 2.]

PHLEGM, a common name for Mucus. [Mucos.]

PHOEBUS. [IDIOLOGY, S. 1.]

PHOLARITE. [MINERALOGY, S. 1.]

PHOSPHATITE, a name proposed for the native Phosphate of Lime derived from organic sources, and usually called Coprolite. The latter term conveys an impression which is not altogether false, for the phosphates of bones of large size are constantly present, and it is questionable if any portion of this phosphate has ever been excremental. Some of these coprolites are of very recent date, but it has already occupied the liveliest attention of nearly all the most eminent investigators in modern science. The names of Davy, Wedgwood, Thomas Young, Wollaston, and the late Mr. T. M. S. Seebeck, Berthollet, and Becquerel on the Continent—testify to this effect. Photography is worthy of special attention from the fact that it requires for its rational and thoroughly successful pursuit a knowledge of chemistry, optics, and physics generally, together with an amount of artistic taste and manual dexterity such as must be useful not only for purposes of mental training, but under a variety of circumstances in actual life. The variety of its parts and aims gives it a special charm for those who like to pursue a complete activity of mind and body; its practical aims are carried on in the doors as in close laboratories. Further it has this charm, that while it furnishes problems of the greatest interest and intricacy for the most advanced philosopher in optics or chemistry, it has its practical processes, which may be readily apprehended, and exercised for purposes of utility or recreation by those who are but little skilled in physical manipulations.

Photography has been so fully treated of by Mr. Robert Hunt, in his "Researches on Light," and in his "Treatise on Photography," and also by the Abbe Moigno, in his "Reperoire d'Ooptique Moderne," that we need not do here more than recapitulate in a brief manner the points of chief importance previously given by those authors.

It may be well to say at the outset, that it was not till the year 1839 that Photography acquired for itself "a local habitation and a name," through the investigations of Fox Talbot and Daguerre, which resulted in the introduction of the two processes known as the Calotype or Talbotype, and Daguerreotype. As usual in the history of art and science, approximations had been attained to by earlier experimenters. It is interesting to inquire into the labours of some of these. Proceeding historically, we shall find that observations relating to the science of photography precede the first attempts at establishing the principles of the art.

In 1729 Petit noticed that solutions of nitrate of potash and muriate of ammonia crystallised more readily in the light than they did in darkness. In 1777 the ill-fated Scheele writes, "It is well known that the solution of silver in acid of nitre, poured on a piece of chalk and exposed to the beams of the sun, grows black. The light of the sun reflected from a white wall has the same effect, but much more evidently, with regard to liquid without solution. Again, "Fix a glass prism at the window, and let the refracted sunbeams fall on the floor. In this coloured light put a paper screwed with luna cornua (chloride of silver), and then let the paper be removed from the light, it will become sooner black in the violet ray than in any of the other rays."

Senebier repeated these experiments, and also experimented on the influence of light in the bleaching of wax.

In 1796 Count Bumford sent to the "Philosophical Transactions" a memoir entitled "An Inquiry concerning the Chemical Properties that have been attributed to Light."
produce in any moderate time an effect upon the nitrate of silver." Davy adds, "In following these processes, I have found that the images of all objects produced by means of the solar microscope may be copied with difficulty on prepared paper. This will probably be a useful application of the method; that it may be employed successfully, however, it is necessary that the paper be placed at a small distance from the camera."

The muriate (chloride) of silver was found to be more sensitive to light than the nitrate. "Even in the twilight, the colour of the moist muriate of silver spread upon paper slowly changed from white to faint violet; though under similar circumstances, the nitrate of silver was insensible upon the nitrate." Davy concludes with these remarkable words: "Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day, is wanting to render this process as useful as it is (now) seen.

From this time the art in England slumbered until 1834, when Mr. Fox Talbot, without knowing what had been done, commenced experiments with the same end in view.

But we must now turn to a neighbouring country, France. In 1813 M. Niépce, of Chalons on the Soane, was engaged in a task identical in conception with that of Wedgewood. He was endeavouring by means of bituminous varnishes and metal plates to fix permanently the images of the camera, and in order to accomplish the object he was engaged on, he carried on until 1827, in which year he presented a memoir with specimens to the Royal Society of London; but as he kept his processes secret no notice was taken of his labours. He died in 1833, and the art was lost for some years. He there however continued his experiments, making pictures in pictures of the surface of bitumen laid upon a metal plate, which he afterwards engraved by ordinary engraver's acid. The rationale of his process is this: Light is capable of hardening a bituminous surface in such a way that the usual solvents of bitumen no longer act readily upon the altered part of the surface, and therefore only the shaded portions of a partially illuminated plate would yield to such solvents as the mineral naphthas, for example, furnish. But when a metal plate had been thus treated, and the image was examined in the camera, the shadows nothing was easier than to etch such a plate by means of aqua fortis, and this was what Niépce did. A plate thus made and prints from it are now in the possession of Mr. Robert Brown, of the British Museum. It is to be hoped that they will be placed in the Museum itself. M. Niépce named his art Heliography.

In 1839 M. Niépce became acquainted with a M. Daguerre, who was noted for his dioramic paintings, and who was, it is alleged, as the first to apply the camera to the reproduction of the camera. A deed of partnership was executed between the two experimentalists, and they jointly pursued their labours until the death of Niépce, in July 1833. A new arrangement of the process was made between his son M. Isidore Niépce and Daguerre.

At length came the memorable year 1839, when the whole scientific and artistic world was startled at the announcement that objects could be made to draw their own pictures with an accuracy and minuteness quite unattainable by hand. In January 1839 the first specimens by Daguerre were shown, but the process was withheld until the month of July. This enabled Mr. Fox Talbot to secure to himself the merit of priority of publication of a method by which sun-drawn pictures could be successfully produced. On the 19th of January communicated to the Royal Society a paper, entitled "Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the Aid of the Artist's Brush." In the same year, the 21st of February in the same year, he gave another communication on the method of preparing sensitive paper and of fixing the images obtained. That the two experimentalists, Talbot and Daguerre, were independent discoverers is evident from the dissimilarity of their processes; the light and camera obscura being the only means strictly in common. Mr. Talbot's method consisted in washing letter-paper over repeatedly with alternate solutions of salt and nitrate of silver, which gave images under the influence of the camera, and these images were fixed by immersion in a strong solution of salt and water, in which the unaltered parts of the chloride of silver were soluble. This process was not very sensitive, and was therefore set aside by Mr. Talbot's later discoveries of 1840.

Let us now examine the nature of Daguerre's process called the Daguerreotype. A plate of silvered copper is highly polished, and then exposed to the vapour of the chemical element iodine, which imparts to the plate a series of black dots in proportion to the quantity of iodine absorbed. The exposure to the vapour was continued until the plate assumed a rosy tint, or simply a deep orange-yellow, bordering on red. The plate was now sensitive, and had only to be exposed at the focus of the camera obscura in order to obtain a picture of the objects in front of it, as perfectly as if they had actually been exposed to light; and this deposit takes place in proportion to the original intensity of light of the image. Thus a picture was produced which represented in shades of black and white, the original optical image seen on the ground-glass screen of the camera.

A solution of the hypsophlite of soda was used to fix the image by removing the compound of iodine and silver which still adhered in some degree the shadows on the plate. Subsequently M. Fizeau improved the appearance of daguerreotypes by imparting to them a warm tinge by a thin film of gold which was thrown down upon the image by a spontaneous electro-chemical action.

The original daguerreotype process was not sufficiently sensitive to be used in portraiture. To Mr. Goddard we owe the great improvement of the introduction of a second chemical agent which now enables us to make pictures in a second of time. In 1840 Mr. Goddard combined bromine with iodine and produced the process known as Goddard's process. In the dull weather of November of that year, he obtained a half-length portrait in a few seconds; Daguerre's process requiring many minutes, even in a strong light.

One of the best modes of procedure now adopted is the following: Take a plate of silvered copper and anodize it by means of tripoli powder and oil of lavender or rosemary, applied by cotton velvet; finishing the polish by clean cotton velvet alone. Then expose the silver to a mixture of iodine and bromine in such a manner that the vapour of the iodine shall act equally upon the surface of the silver plate, to which it imparts a coating which is seen to be coloured when examined by light reflected from any white screen, a piece of paper for example. As soon as the plate has assumed an orange-yellow colour it is developed in water and then exposed to the vapour issuing from a peculiar red compound of bromine with lime, called 'bromide of lime.' Over this it absorbs bromine, and assumes a rose tint, and as soon as the plate has been obtained, the plate must be removed and again exposed to iodine and bromine for a few seconds, the rose colour has deepened into a plum tint. The plate is then ready for exposure in the camera obscura. No time can be wasted for these various exposures as temperature influences the results. After such preparation a few seconds are sufficient. The plate must be prepared in a room which can be darkened, the light of a candle, or that obtained through yellow glass being alone used at the last iodizing, and in some of the subsequent operations. After exposure in the camera the plate is exposed to the vapour of mercury for a few minutes, the mercury being at a temperature of about 180° Fahr. Here the picture is developed by the action of the mercury upon the bromo-iodised surface, the mercury being, it is believed by some, deposited in the plate in proportion to the amount of light which fell upon its surface during its exposure in the camera. On its removal from the mercury box the plate is partially fixed by washing its surface with a strong solution of hypsophlite of soda. The final fixation is effected by boiling upon the plate a solution of a double salt, called hypsophlite of soda and gold. The image is now fixed upon the plate, and may be coloured by brushing over it colours in very fine powder. The image should be kept as to exclude the vapour of lime from the atmosphere under which it is usually found in large towns. Sulphuric and hydrochloric acid will affect the surface.

Having given an account of the daguerreotype, we might proceed to relate the history of Mr. Fox Talbot's researches, which led to the invention of the first successful process in photography on paper; but as these will be found detailed in Mr. Talbot's work 'The Pencil of Nature,' and in the Specifications of his Patents, we prefer to pass at once to con-
sider a process which has now almost superseded all others, and which consists in fixing the image on a film, on glass, on collodion, containing also iodide of silver with an excess of nitrate, the development being accomplished by pyro-gallic acid in the place of gallic acid. The analogy is complete, but the latter materials improve very much the ultimate result.

Collodion is made by dissolving in ether and alcohol cotton-wool which has been altered in its properties by treatment with strong acids. The following is a good mode of proceeding, and is referred to the researches of T. and J. R. Adams.

Take of pure nitrate of potassium 150 grains; 250 grains, of nitric acid (specific gravity 1.833 about 1834) draehms, of water 12 draehms; stir together, and when at a temperature of from 150 to 160° Fahr., add, bit by bit, 15 grains of cotton-wool to each ounce of the acid mixture. Allow the cotton-wool to soak for four or five minutes, and then wash it many times in water until it is quite free from acid. Then, to make the collodion, take 9 grains of the dry cotton, and add 6draehms of pure ether (ep. gr. 7.85 to 7.88), and 3draehms of nitric acid (specific gravity 1.833 about 1834) to the above solution, and the solution once dissolved. In another bottle prepare what is called the 'iodising solution' by taking alcohol (ep. gr. 818 to 830) one ounce, iodide of potassium 12 grains, iodide of cadmium 4 grains, and benzine 3 draehms, and mix all in the above solution for use. To make 'iodised collodion,' mix six draehms of collodion with two draehms of the iodising solution; this mixture changes by keeping, and should therefore be made only in moderate quantities. Having prepared the iodised collodion, a plate of glass is covered with it by pouring a quantity on the centre of the plate, and then allowing the liquid to flow to the corners in such a way that the glass shall be uniformly covered; the excess is then run off at one corner and the bottle set aside for the purpose. After a few seconds the surface of the plate forms a firm tough skin tight fit for immersion—in the dark—in what is called the 'nitrate bath.' This bath is made by dissolving 30 grains of nitrate of silver in one ounce of distilled water. The nitrate of silver should be pure, and free from excess of nitric acid, and it should be saturated, when in solution, with iodide of silver; a little acetic acid, too, may be added. The plate is immersed in this bath for a few minutes, drained, and then exposed in the camera obscura. To develop the image, a solution of hypo-sulphite of soda, 1 ounce, nitric acid, 1 ounce, water 100 grains, is fixed on a strong solution of hypo-sulphite of soda, in which it is eventually mered, or, instead, a weak solution of cyanide of potassium may be poured upon the plate, and left there until the yellow film of iodide of silver disappears. The plate is then washed and dried, and protected by a film of varnish: amber in chloroform being usually preferred for this purpose.

The picture thus obtained is, as in the calotype or Taltotype process of Mr. Fox Talbot, a negative one, that is to say, a picture having its light and shade reversed; though by modifying the collodion process direct positives may be at once obtained; a good negative, however, is a more valuable acquisition. In order to obtain copies correct in light and shade and position, a positive has to be made. There are many processes by which this may be done, but we shall only detail one which answers perfectly. Take the white of an egg and beat up, with every fluid ounce of it 12 grains of common salt; remove the froth thus obtained, and continue beating until all has become froth. Leave this froth to itself, and the greater part of the water will separate and be again precipitated. Pour the liquid into a flat shallow dish, and upon it place carefully, so as to exclude bubbles of air, a sheet of thin paper, French paper is usually chosen; leave the paper for two or three minutes, and then only take it up, as in the calotype albumen.' As the white of egg mixture is now called. Then carefully remove the sheet, and pin it up by a corner to dry. This operation can be carried on in daylight. To make this paper sensitive, it is floated upon a solution of nitrate of silver: the white of egg paper floats on, and remains white. Here it is left for two or three minutes, and then removed and suspended to dry. This last operation must be per-
of the Paris Academy of Sciences, in our own Royal Society's 'Transactions,' and above all in the journals of the various Foreign Academies.

PHY, CIS, a genus of fishes belonging to the family Gadidae. It has an elongated body; two dorsal fins, the first short, the second long; ventral fins with a single ray only at the base, afterwards divided; chin with one barbel. It is named after the Common Fork Beard, a rare fish on the British coasts. It has been taken most frequently in Cornwall. It is about two feet in length, but not very good eating.

PHYSIC, PRACTICE OF. The more common diseases of the human system are treated of in the 'Penny Cyclopædia,' either under the head of the particular disease, or the organs or system of organs disordered. In the First Supplement, under the article Necessity, a classification of diseases will be found. In the present article, some forms of disease are noticed which have either been recently described or on which new light has been thrown by recent research. The subjects have been arranged for the convenience of reference in an alphabetical form.

ACCLIMATIZATION is a term applied to that change in the human system produced by residence in a place whose climate is different from that to which he has been accustomed, and which enables it to resist those causes of disease which render it injurious under the first treatment. A person is thus rendered similar in constitution to the natives of the country which he has adopted. This subject is one of great importance, and has not yet received the attention which it deserves. It appears that the white races attain their highest physical and intellectual development, the greatest amount of health, and reach the greatest age, above 40° in the western and 45° in the eastern hemispheres. Whenever they pass below these latitudes they begin to deteriorate and exhibit unmistakable symptoms of decadence in both health and strength. The same law holds good with the dark races of the tropical parts of the earth. The negro who lives in the interior of Africa, is killed by cold. The limits of his health and strength are at 40° or 45° north or south. If he proceeds to higher latitudes, he deteriorates and becomes exterminated. In the northern states of America the mortality of the black population is double that of the white.

"The laws of climate show that each race of mankind has its prescribed salubrious limits. All of them seem to possess a certain degree of constitutional liability by which they are able to bear, to a certain extent, great changes of temperature and latitude; and those races that are indigenous to the equatorial or tropical regions, are the most insensible to the extremes of other latitudes. The inhabitants of the arctic regions, as also of the tropics, have a certain pliancy of constitution; and while the inhabitants of the middle latitudes may endure 30° south or 30° north with comparative impunity, the Eskimians in the Arctic North, and the Negroes in the equatorial regions, on the other hand, have no power to withstand the vicissitudes of climate encountered in traversing the 70° of latitude between Greenland and the equator. The fair races of northern Europe below the arctic zone find Jamaica, Louisiana, and India, to be extreme climates; and they and their descendants are no longer to be recognised after a prolonged residence there. When an Englishman is placed in the most beautiful part of Bengal or Jamaica, where malaria does not exist, and although he may be subjected to no attack of acute diseases, but may live with a tolerable degree of health his threescore years and ten, he nevertheless ceases to be the same healthy individual he once was; and, moreover, his descendants degenerate. He complains bitterly of the heat, and becomes tanned to a rich plum plethoric frame becomes attenuated; his blood loses fibrine and red globules; both mind and body become sluggish; gray hairs and other marks show that age has come on prematurely—the man of forty look forty, and sooner or later the superfluous duration of life is shortened (as shown in life insurance tables); and the race in time would be exterminated if cut off from fresh supplies of emigrants from the home country. Our army medical historians tell us that our troops do not become homesick in the tropics; but in the habitations on the distant land affords no immunity from the diseases of its climate, which act with redoubled energy on the stranger from the temperate zones. On the contrary, the mortality among officers and troops is greatest among those who remain longest in those climates." (Johnson, Martin, Tulliboch, Macpherson, Boudin.)

"Dr. Macpherson also makes the significant remark, that the small mortality among officers compared with soldiers, in India, is due to the greater facilities they enjoy of obtaining changes of situation, or cool climes when they fall sick. Although the constitution of the man may be so modified that comparative health may be retained, yet there is a morbid degradation of the physical and intellectual condition of the man; and when his descendants are taken back to their native climate, they may yet revert to the healthful standard of their original types. The good effects of limiting the period of service of our troops abroad to three years, has shown this in sustaining for a greater period the strength of the regiments; a prolonged residence of the European regiments in India having been followed by the most disastrous results. "European regiments in India have melted away like the spectres of a dream. A regiment long men form this year a regiment: a year passes, and one hundred and twenty-five new recruits are required to fill up the broken column; and eight years having come and gone, not a man of the original thousand remains in the dissolving corps."

"With regard to the M. de Fuzelier European regiment, for instance, Dr. Arnott has shown that its losses average 104 per 1000 per annum; a loss equivalent to the entire absorption of the regiment in nine years and seven months. In Bengal also it is an ascertained fact, that a British regiment is reduced by a loss of 1000 men in nine years, and seven months in favourable times, and with all the improved conditions of the service. Dr. Arnott's statistics show that the Bengal army loses annually 9 per cent. of its numbers, giving a total loss of eight years of upwards of 14,000 men out of an army of 150,000 men."

(Atten's 'Handbook of Medicine.')

"In the island of Ceylon the rate of mortality has been recorded among five different races of which the British troops are composed. The following table gives the result:

<table>
<thead>
<tr>
<th>Race</th>
<th>Annual death in 1000 men</th>
</tr>
</thead>
<tbody>
<tr>
<td>Native troops of Bengal and Madras</td>
<td>12</td>
</tr>
<tr>
<td>Troops recruited on the coast of Ceylon</td>
<td>23</td>
</tr>
<tr>
<td>Malays</td>
<td>24</td>
</tr>
<tr>
<td>Negro troops</td>
<td>69</td>
</tr>
<tr>
<td>English troops</td>
<td>69</td>
</tr>
</tbody>
</table>

Although from these facts it would appear there is an insuperable barrier to the prolonged occupation of tropical countries by white races, yet much may be done by attention to the laws of health and disease. One cause of the great amount of mortality amongst Europeans in the tropics is that they are in habitually cold climates; when they arrive in the hotter parts of the world. An attention to diet, clothing, and residence, would do much to remove many of the causes of disease. It would appear that not amongst the natives of these countries, but made their way from warmer countries, and that changes gradually produced in the constitution, as by the slow advance of peoples north or south, may overcome that tendency to succumb which is so evident in the rapid removal to which the above data refer. The question of the permanent occupation of tropical countries has become one of vital importance to the two great European governments of England and France. How this can be done at the least expense of human life can only be ascertained by the study of the laws which regulate accultilation.

Addison's Disease. The name of Dr. Addison, physician to Guy's Hospital, has been connected with a diseased condition of the system, which is made apparent by a discolouration of the skin. Hence this disease is called 'Bronzed Skin.' The existence of this discoloured skin has long been known as a symptom of certain cachectic states of the system; but Dr. Addison was the first to point out that this state of the skin always existed in connection with actual discompositions of the supra-renal capsules. These bodies belong to the class of ductless glands, and till the time of Dr. Addison's researches upon bronzed skin appeared, little was known of their use and functions in the human body. The following conclusions with regard to these bodies arrived at by Dr. Martby as the result of his experiments —

1. The supra-renal capsules are not solely fastid organs.
2. They are not absolutely essential to life.
3. The removal of the right is generally more fatal than the left.
4. That convulsions do not necessarily follow their removal.
5. That the absence of their function is attended neither by amnesia nor debility.
6. That death follows an experiment, it occurs as the result of injuring neighboring parts.
7. That absence of the supra-renal bodies is not proved to be a cause of death, but a consequence of the transformation of hematin or in increasing the formation of blood-crystals.
8. That the suppression of the supra-renal capsular function is not attended by an increased deposit of pigment in the skin or its appendages.
9. That the presence of the connection of the bronzed skin and supra-renal capsular disease is more likely to be solved in the dead-house than in the physiological laboratory.

These conclusions were chiefly arrived at by experiments on rats, but they would seem to indicate that the connection betwixt a bronzed skin and supra-renal capsules is not clearly made out.

The distinguishing features of the disease to which the name bronzed skin has been given, are general languor and debility, great feebleness of the heart's action, irritability of the stomach, a peculiar change of colour of the skin, and these symptoms usually occurring in connection with a diseased condition of the supra-renal capsules. The general symptoms are in fact those of anemia, or cases in which the blood is not of the proper character. The patient is said to have this discoloration of the skin, that it usually increases with the advance of the disease. "The anemia, languor, failure of appetite, and feebleness of the heart become aggravated; a darkish streak usually appears upon the commissure of the lips. The patient is emaciated and dry, and the dry harsh condition of the surface so commonly observed in ordinary malignant diseases; the pulse becomes smaller and weaker, and without any special complaint of pain or uneasiness, the patient at length gradually sinks and expires. In one case, which may be said to have been acute in its development as well as rapid in its course, and in which both capsules were found universally diseased after death, the mottled or checked discoloration was very manifest, the patient was emaciated, the heart of the patient was so emaciated and vomiting urgent; but the pulse, instead of being small and feeble as usual, was large, soft, extremely compressible, and jarring on the slightest exertion or emotion, and the patient speedily died." (Addison.)

Although the connection between the state of the skin and the disease of the capsules was exhibited in all Dr. Addison's original cases, many exceptions have been recorded. Cases have occurred in which extensive disease of the suprarenal capsules has been observed without the bronzed skin, and cases of bronzed skin have been seen where no disease of the supra-renal capsules could be detected after death.

Dr. Harley, in the paper referred to, concludes—
1. That bronzed skin may exist without the supra-renal capsules being diseased.
2. That complete degeneration or total absence of the supra-renal capsules may occur without any bronzing of the skin.
3. That bronzed skin may be associated with a variety of differently-marked conditions of the system, among which a prominent one is disease of the suprarenal capsules.

4. That bronzed skin may be present without any derangement of the other functions of the body being observed. ('British and Foreign Medico-Chirurgical Review,' No. 42, 1848.) Dr. Harley is of opinion that the general symptoms in this disease are produced by a "diseased state of the solar plexus per se, on by irritation of the ganglionic system of nerves, caused by the close proximity and intimate connection of diseased supra-renal capsules." The blood has been examined by the microscope in some of these cases, and found to present an increased quantity of the white cells, as the transformation of the disease known as Leucocytoma. [Blood, Diseases or.]

The microscopic character of the skin has been carefully examined in this disease, and it has been found to present the same pathological changes observed in the skin of the black man. The pigmentary matter of the skin is found to be increased, and existed in larger quantities in the under than in the upper layers of the epidermis.

The treatment of this disease is not affected by our knowledge of its cause. The remedies which would be applicable to bloodless and depressed conditions of the system should be used here. Tonics, nutritious diet, fresh air, and the means resorted to for restoring health in anemia and iron in their various forms, are recommended.

The prognosis in this disease is unfavourable, although cases are reported in which recovery has taken place.

Anemia, a diseased condition of the human body, in which is implied either a morbid condition of the blood, or a relative insufficiency of the active constituents. This disease is also called oliganemia and spasmnemis, terms which, like anemia, express a deficiency or paucity of the constituents of the blood. This state of the system is generally indicated by the excessive paleness of the skin, and the sense of the heart being in the center of its movements. It is generally a nervous disease, the conjunctiva is of an unnatural white, having a pearly lustre. The veins on the surface are small, blue, and collapsed. General symptoms are frequently attended with derangements of the nervous system. There is frequently violent pain in the head, and not infrequently, excited and ordered sensations, as singing in the ears and flashings before the eyes. The whole surface of the body is frequently prematurely tender, the slightest touch causing the patient to start. The course of the spleen is frequently excessively tender, leading to the supposition that there is spinal irritation. The circulating system is deranged; palpitations of the heart come on after slight exertion. The pulse is mostly small, feeble, and quick, excited to rapid action on slight motion, at rest diminutive and slow. The patient is generally lassitude and inability to take much exercise. This disease is accompanied with disturbances of the circulatory system, which may be detected by means of the stethoscope. There are heard in the heart are a 'bell-like' sound, and heard in the heart is a 'belting' murmur of varying intensity, and is heard most distinctly at the apex. This sound is not present in all cases of anemia, nor is its occurrence diagnostic of anemia; but it is very important to know that it may be entirely dependent on the anemic condition, and removed with it. The arterial murmurs are not frequently heard; they are synchronous with the beat of the pulse, and when present may even be recognized by the character of the pulse. The venous murmurs are generally present, and may be heard in the neck, ears, and various buzzing, humming, musical, and singing murmurs. "They are most frequently heard on the right side of the neck, at the junction of the external and internal jugular vein." (Aitken.)

The venous murmurs are seldom absent to a greater or less extent in anemia.

When the blood of anemic persons is examined under the microscope a deficiency of blood globules is observed. The number of blood corpuscles may be from 20 to 30 millions in 1 cubic inch of blood globules in 1000 of blood. The other constituents of the blood, as far as observations at present go, seem to suffer little alteration.

The cause of anemia are anything acting on the system by which the production of blood is diminished or the healthy development of the blood cells prevented. Thus, amongst the causes of this disease we may reckon: 1. Want of food. 2. Want of proper food. 3. Indigestion or imperfect nutrition, from whatever cause. 4. Derangement of the liver, spleen, &c. 5. Haemorrhages, as from haemorrhoids, the stomach, lungs, wounds, &c. 6. All extensive discharges from wounds, ulcers, or mucous surfaces.

A knowledge of the cause of anemia at once suggests its treatment. Where it depends on a want of food altogether, or of proper food, then food of a proper kind must be supplied. Where improper food, as alcohol, produces imperfect assimilation, it must be withdrawn. Deficient nutritive changes often come on as the result of impure air, and change from an impure to a pure air often acts most beneficially. In certain cases dependent on imperfect blood-cell formation great benefit results from the administration of iron. Cases are recorded in which, under an iron treatment, the blood corpuscle-count increased from 38 to 72 millions. Other tonics may also be administered with advantage. In cases of anemia in marshy districts quinine is of great service.

Baum's Disease. An affection of the kidneys, having very definite symptoms, and exhibiting uniformity of struc-
several stages or varieties, and some discussion has taken place as to whether the symptom of albumen in the urine may occur in several distinct classes of conditions of the kidney. There is no doubt that albumen may be found in the urine in even functional derangements of the kidney; but the term Bright's Disease is very conveniently applied to all those forms of structural change in the kidney which are accompanied with albuminous urine.

The general symptoms accompanying this disease vary according to the intensity of the disease and the condition of the patient. One of the first symptoms to which the physician is made aware, is the presence of dyspepsia. This may occur in the skin or in any of the cavities of the body. It is frequently noticed in the face; and in all varieties of this disease an effusion of fluid is observed underneath the conjunctiva, producing the appearance of a watery eye. A discolored discoloration of the mucous and serous membranes are very common accompaniments of Bright's disease. The heart also is frequently affected, and pericarditis and endocarditis are observed. Affections of the brain are also not infrequently present, especially in the more severe cases arising from the poisoned condition of the blood.

In all cases of this disease, the urine contains albumen. This is easily detected either by coagulating the albumen by heat, blood, or urine, whilst healthy urine has a specific gravity of 1.020. It contains less urea than healthy urine. Under the microscope it also presents appearances indicative of the nature of the disease. These appearances are very characteristic of the minute tubes of the kidneys, formed by substances produced in various stages of the disease. They are thus classified by Dr. Bennett:

1. Excretive casts, consisting of the coagulated exudation only which is poured into the tube during the inflammatory stage.
2. Desquamative casts, consisting of masses of the epithelium lining the tubes, and occurring in all stages of the disease.
3. Fatty casts, consisting of patches of epithelium as in the last, but which have undergone a fatty transformation by the accumulation of a greater or less number of fatty granules in its cells.
4. Waxy casts, presenting an exceedingly diaphanous and structureless substance. They are frequently associated with the last two.

Dr. Bright originally described three stages of this disease, but later observers have recognized six.

1. The natural form, in which the kidneys are enlarged, and contain an increased quantity of blood. In this stage only a small quantity of urine is passed containing the excretive and desquamative casts.
2. In this stage the kidneys are enlarged to nearly double its usual size, and the surface is highly granular in its appearance. The tubes of the kidney are obliterated by the inflammatory deposit. The urine is very albuminous, and of light specific gravity.
3. The kidney presents a mottled appearance. It is probably a transition from the first to the second stage.
4. In this stage the kidney is large, dense, and white. The tissues of the kidney have become charged. The urine is scanty, of low specific gravity, and defective in urea and other excretory matters.
5. In this stage the kidney is hard, granular, and contracted. The kidney is smaller than in health, the surface is uneven and pocked, the tunic adherent. There is no deposit in the tubes, but fibrous matter has been deposited in the walls of the kidneys, and the tubes are stringed. The urine may not contain albumen. Its specific gravity is sometimes as low as 1.006.
6. This stage has been called the 'cousine kidney.' The organ is large and dark. The specific gravity of the urine is high.

The presence of fatty matter in the casts of the kidneys may occur in any of these stages, and does not appear to exist as a separate form of the disease.

This discussion which will unduly excite the action of the kidney. Thus it comes on as the result of spirit drinking, which powerfully excites the action of the kidneys. Exposure to cold and diminution of the action of the skin will also produce it. It comes on frequently after scotomata, when the skin is highly susceptible of any diminution of temperature.

The treatment must be active in the early stages. Purifications may be given and blood abraded locally, and the patient kept in bed and placed in a suitable situation. Operation is beneficial. When chronic, diaphoretics and diuretics are both admissible. Amongst the former, Dover's powder and warm baths, and the latter, bitartrate of potash and digitalis. The patient should be protected from cold; a warm climate is serviceable; and a nutritious but non-stimulating diet, with fresh air and exercise, are desirable.

Blood, Diseases of. A large number of diseases are now referred to disordered conditions of the blood. Amongst these are sickness—consumption. Continued Fevers, Eruptive Fevers, Syphilis, Mercurial Poisoning, Rheumatism, Gout, Scrobutics, Obesity, Leucocytosis, and Pyemia. With the exception of the two last, these diseases have been treated of in the 'Fenny Cyclopaedia.'

Leucocytosis is a term applied by Dr. Bennett, of Edinburgh, in 1845. The name is derived from the fact, that in these cases the white or colourless corpuscles of the blood are increased in number. This state of things is brought about by loss of blood, chronic diseases, more especially affections of the lymphatic glands and spleen. It is accompanied by debility, wasting, cough or diarrhoea, and a generally unhealthy condition of the system. The increase of the white corpuscles of the blood, which are called leucocytes, is due to two causes: first, to the destruction of the red corpuscles, and secondly to the liberation of the corpuscles from the lymphatic glands and spleen. The leucocytes are the organs most extensively affected. The occurrence of this disease has led to highly interesting inquiries as to the origin and nature of the white cells of the blood, which are known as leucocytes. Dr. Virchow in his work on the 'Principles and Practice of Medicine,' (1858), gives the following conclusions as to the result of his own elaborate and carefully conducted inquiries:

1. That the blood-corpuscles of vertebrate animals are originally formed from the lymphocytes of the lymphatic glands, and that the great majority of them, on joining the circulation, become coloured in a manner as yet unexplained. Hence the blood may be considered as a secretion from the lymphatic glands, although in the higher animals that secretion only becomes fully formed after it has received colour by exposure to oxygen in the lungs.

2. That in mammals, the lymphatic glandular system is composed of the spleen, thymus, thyroid, supra-renal, pituitary, pelvic, and several accessory glands.

3. That in fishes, reptiles, and birds, the coloured blood-corpuses are nucleated cells, originating in those glands; but that in mammals they are free nuclei, sometimes derived as from such glands, at others developed within colourless cells.

4. That in certain hypертrophies of the lymphatic glands in man, their cell-elements are multiplied to an unusual extent, and under such circumstances find their way into the blood, and constitute an increase in the number of its colourless cells. A corresponding diminution in the formation of free nuclei, and consequently of coloured corpuscles, must also occur. This is leucocytosis."

The treatment of this disease must be directed to the removal of those affections by which it is preceded and accompanied. Unfortunately, these are mostly of such a nature as to resist all treatment after the white cells have been discovered in the blood.

Pyemia. Put in the blood. By this term is understood a peculiar and dangerous disturbance of the system, supposed to be produced by the admixture of pus with the blood. In the cases in which this disease occurs, the pus is supposed to gain access to the blood from a suppurating surface in which the veins are opened, or by the production of pus on the surface of the vegetable matter, or of an erupting phlebitis. Many cases, however, of this disease have been recorded in which no open suppurating wound of the body could be discovered.

The removal of pus in more or less violent shivering fits. When suppurating surfaces exist they dry up, or the discharge becomes greyish and fetid, the surfaces of the wound assume a withered, flabby aspect. The patient becomes exceedingly languid and exhausted, and is sometimes plunged into a deep stupor, or has occasional delirium. On the inspirations increase, the breath exhales a purulent
colour, the lungs are congested, the skin becomes daily more yellowish, articular pains with swelling, and intra-synovial effusion occur successively in several of the joints. The tongue is dry, and coated with a brown fur; the teeth and lips are covered with sores, the abdomen is tender and frequently tympanitic, the pulse is quick and becomes tremulous and thready, the head is hot and dull, and if the patient examine himself, the voice is lost, and the patient sinks from the fourth to the tenth day.

After death abscesses are found in the lungs, liver, spleen, brain, kidneys, heart, pleurs, joints, muscles, and the subcutaneous regions. In many cases pus-cells, or an increase of the white corpuscles, have been found in the blood. This increase is not, however, a diagnostic symptom, as many cases have occurred in which the white corpuscles have not been noted and distinguished in the blood from the pus-cells, and have been supposed to be identical (have been observed.

The pathology of this disease has excited much discussion. Whilst some have regarded it as entirely dependent on the introduction of pus into the blood, others maintain that it depends on the introduction of a peculiar poison into the blood. Dr. Bennett injected pus into the blood of an animal without producing ill effects, and the above symptoms came on in the animal, and the symptoms of scarlatina, were more probable therefore that the disease arises from a peculiar state of the blood, either arising from vital changes in itself, or produced by the introduction of an external poison.

This disease is most frequently fatal, and no one plan of treatment can be laid down. Where suppuring surfaces are present these must be attended to, and accumulations of pus in abscesses should be removed by free incisions. The system must be supported by stimulants. Large doses of quinine have been recommended when only a few distinct symptoms resembling each other have been included.

Dr. Jenner has given the following summary of the various forms of fever now recognised as follows:—

**Fibrículos.**—A disease attended by chilliness, alternating with a sense of heat, headache, white tongue, confined bowels, high-coloured scanty urine, hot and dry skin, and frequent pulse, terminating in from two to seven days, and having for its cause exposure, over-fatigue, &c. (t. e.) the cause of fibrícula is not specific.

**Recurrentes:**—Disease arising from a specific cause, attended by rigors and chilliness, headache, vomiting, white tongue, epigastric tenderness, confined bowels, enlarged liver and spleen, high-coloured urine, frequent pulse, hot skin, and occurring at definite intervals. It resembles a tertian fever, but with less esence in from five to eight days; in a week a relapse (i.e.) a repetition of the symptoms present during the primary attack. After death, spleen and liver are found considerably enlarged; absence of marked congestion of internal organs.

**TYPHOID FEVER.**—A disease arising from a specific cause, attended by rigors, chilliness, headache, successive crops of rose spots, frequent pulse, sonorous rale, diarrhoea, fulness, resuscitation, and tenuity of the abdomen, gurgling in the right side of the abdomen, increased spleenic dulness, delirium, dry brown tongue, and prostration, and terminating by the 30th day.

After death enlargement of the mesenteric glands, disease of Feyer's patches, enlargement of the spleen, disseminated haemorrhage, and inflammation of the heart, and blood vessels in this country as a variety of croup, and by others as a form of scarlet fever. Now that it has appeared, few observers could be found who would not agree that it is a disease with specific symptoms. The invasion of this disease has been looked on with peculiar alarm, as there is something very sinister belonging to the contagious or communicable class. It is also very fatal, and already a large amount of mortality has been caused by it in this country.

The symptoms of this disease are the formation of a false membrane upon the surface of the mucous membrane of the larynx, and the fauces. This membrane is of a whitish or ash-grey colour, and frequently extends forwards from the pharynx and tonsils to the soft palate and into the nostrils, and sometimes covers all the mucous membrane of the larynx and the trachea, and in this respect it differs from croup, and may be easily distinguished from it. When the
membrane is found in the larynx or trachea, it is always sub-
sequent to its appearance in the fauces. At the commence-
ment of the disease, the membrane is seen in the form of a
white spot on the pharynx or tonsils, from which it gradually 
extends all around. As it goes on, and the disease becomes more 
severed, the membrane is found to have spread to the base of the tongue, and when the tongue is loaded, the pulse is frequent and feeble. In the early stages it may be taken for scarlet fever. But there is no active 
fever, nor eruption of the skin, no redness of the papillae of 
the tongue, and when the patient recovers, no disappearance of the 
membrane as is constantly the case in that disease.

The general symptoms are those of low fever. The dis-
case sets in with shivering and intense depression, there is 
dryness and tingling of the throat and ears, difficulty of 
swallowing followed by flatulence. As soon as the tongue is loaded, the pulse is frequent and feeble. In the early stages it may be taken for scarlet fever. But there is no active 
fever, nor eruption of the skin, nor redness of the papillae of 
the tongue, and when the patient recovers, no disappearance of the 
membrane as is constantly the case in that disease.

The prognosis in these cases is unfavourable. This 
disease generally terminates life by extending to the air pas-
sages and producing effusion in the glottis, which specially 
tends to cause death.

This disease is from the beginning attended with a great 
depression of the vital powers, and its treatment demands 
that the vital processes should be sustained. A purgative 
may be given at the onset, but in most cases wine may be 
administered to keep the bowels open. The writers also speak highly of the chloride of potash adminis-
trated in the same way as in scarlet fever. To this may be 
added the preparations of ammonia. Quinine has also been 
highly recommended, with good effect. In some instances, 
the cases have been kept in a local treatment. Two remedies have been generally 
employed, nitrate of silver and chloricine. The nitrate of 
silver is applied in the proportion of one drachm to an ounce 
of water on a sponge several times in the course of the day.

Dr. Watson recommends the use of a solution of 
chlorine in water. This relieves the fetid smell which is 
very disagreeable to the patient and those around.

This disease occurring in districts, and attacking in su-
cession the members of a family, has led to the conviction 
that it is contagious. As it is so dangerous a disease, it is 
well to act on the doubt, and to take those measures which 
would be adopted in the case of contagious diseases, as small-
 pox and scarlet fever.

Guarnaschelli in 1821, by veterinary surgeons to 
a disease affecting horses and cattle. It appears in the 
form of a suppurative disease of the mucous membrane of 
the nose and of a suppurative eruption. The former is sometimes 
called glanders and the latter farcy, but the two often occur-
together. The glanders is the result of an attack of the 
other. In 1821, Mr. Muscroft drew attention to the fact 
that this disease could be communicated from the horse to 
the human system. In the same year cases occurred in Germany, 
and since then it has been demonstrated by a large number of 
cases that this disease often spreads from the horse to 
man. When it attacks man it is characterised by vascular 
injection of the nasal mucous membrane, on which chancre-
like sores are formed, extending to the frontal sinuses and 
neighbouring mucous surfaces from which a profuse and 
offensive discharge flows. At the same time a tubercular or 
putrid ulceration appears upon the skin, followed by sup-
putrating bloody or gangrenous ulceration in various parts.

These symptoms may be either acute or chronic. In the acute 
case the pain is severe, and the disease is quickly fatal. In 
chronic cases the local affection alone presents itself. The 
acute disease is ushered in by rigors, pains in the back and 
limbs. These symptoms are followed by phlegmonous tumours 
in various parts of the body, which are accompanied with 
pain and distressing affection of the abcesses or ulcers.

At the same time a discharge takes place from the nostrils of a 
matter more or less purulent, viscid, and mixed with blood. The 
eyelids frequently become tumefied, and discharge a thick 
serous exudate. A matter, that is to say, is formed and 
empties itself. The patient is accompanied by 
pro 
and intermittent. The tongue is at first loaded with white 
se, which afterwards becomes brown or black. Diarrhhea 
and tympanitis often come on in the course of the 
disease. This disease is generally fatal from the seventeenth to the 
thirty-first day. In the chronic cases the febrile symptoms 
are not so severe. They last about a month. A twelvet, when their 
ahed has been known to elapse before a patient has recovered or died.

There is no doubt that these symptoms are the result of a 
poison introduced into the system of man from the horse. 
In all cases contact with glandered horses has been ascer-
tained, and in the horse the disease has been traced to the 
lower parts of the body. Matter has been taken from the ulcers and mem-
embranes in men and horses have been inoculated, and the 
disease has been produced. The disease has also been pro-
duced by compelling animals to swallow the poisoned 
matter in their food. There can, therefore, be no doubt that 
the poison can be absorbed both from mucous and cutaneous 
surfaces. This being ascertained, it becomes more than ever 
necessary to prevent contact with glandered horses. Such 
horses should be kept as far as possible from the houses of 
the sick and healthy, and the dwellings of men who have 
had contact with them should be kept perfectly isolated.

Mr. Turner inoculated two young donkeys, and in one of 
the maxillary glands became tender on the second day, and the 
discharge took place from the nose on the third day, whilst 
in the second they became swollen on the third day, and 
the discharge took place on the sixth. Cases have been recorded in which the incubation of the poison must have 
taken at least three months. In the human being the 
poison has remained latent from two to eight days after 
course.

This disease in its acute form is very fatal. Of fifteen 
cases recorded by Rayer only one recovered. Of the treat-
ment, therefore, little can be said as a matter of experience.

The general symptoms in the latter stages are those of low 
malignant fever, and a stimulant plan of treatment is indi-
cated.

Cased have been bled, and the blood was buffed 
and cupped, but there is no reason to believe that the bleeding 
did any good. In the chronic forms of the disease recovery 
are more frequent. The symptoms indicate the necessity of a 
general treatment.

Microscopic Diagnosis. The recent improvements in the 
construction of the microscope have not only rendered this 
instrument necessary in physiological and pathological in-
vestigations, but essential as a means of diagnosis in many 
diseases of the human system. The very general 
requirement for this instrument as an important aid to the eye in 
examining minute structures and objects, has led to the 
construction of various forms adapted for the use of the 
medical man. The description of this instrument will be 
found in the article Microscope, and an account of the 
methods of using it under Microscope, Urns or, in the second 
supplement of the 'Penny Cyclopaedia.' In the present 
article the application of this instrument to the diagnosis of 
diseases will alone be referred to, and the subject may 
be divided under the heads of Diseased Structures and 
Diseased Secretions.

Diseased Structures.—1. Cancer. The distinction be-
 tween cancer and other forms of growth in the 
human body, is one of the most important departments of 
diagnosis, as upon this depends a just estimate of the action 
of any particular system of treatment, and the solution of 
the question of the curability of cancer. There can be no 
doubt that, although the mind may have no claim to be regarded as such; whilst others, with a 
true cancerous character, have been overlooked. Although 
the microscope cannot in all cases decide the character of a 
questionable alteration, it has nevertheless thrown great 
light on the subject. Cancer exudation generally presents three forms, which, however, are con-
stantly found running one into the other. These have been
named squilimus, encephaloma, and colloid cancer. In all these forms certain cells are discovered by the aid of the microscope, called cancer-cells. These cells may be round, oval, cunoid, spindle-shaped, oval, long, square, heart-shaped, or of other indescribable forms. In size they vary from 4 to the 6th of an inch in diameter. The cell-wall when young is smooth and distended, but when old it becomes roughened and less translucent. These cells contain in their interior always one nucleus, often two, and sometimes a larger number. These nuclei vary in size. Besides the nuclei the cells contain a colourless fluid, which is at first clear, but afterwards becomes opalescent from the presence of a colloidal matter. The addition of young water makes the cells become enlarged by its absorption into their interior. On adding to them acetic acid, the young cells become absorbed, whilst the older cells are rendered more transparent, and the nuclei remain unaffected, or become thicker from contraction.

In squilimus these cells are found either in distinct cysts or isolated amongst a mass of filaments which vary in size, and run in different directions, sometimes forming waved bands, and at others an inextricable plexus. In encephaloma the same fibrous structure is observed, but it is looser. In the softer parts no traces of fibres are observed, and the cancer-cells abound. When blood is extravasated in this structure, it constitutes the form of cancer known by the name of hemangina. This form is also to consist of a fibrous structure, but which is so arranged as to form argole or loculi, which are filled with a gray or amber-coloured glutinous matter. This matter is sometimes quite fluid. Sometimes it presents the nucleated-cells characteristic of cancer.

Sometimes the cancerous matter is found mixed with oil globules, and crystals of cholesterol and margarine. At other times it becomes hardened by the deposit of calcareous substances. This indicates the tendency of the cancer to assume the forms of fatty and mineral degeneration. (Bennett, 'Principles and Practice of Medicine.')

2. Tubercle. This form of diseased structure is found in the lungs and other organs. The generative tubercle presents a yellowish or dirty white colour, and has a consistence varying from that of cream to a substance resembling tough cheese. A small portion squeezed between glasses and examined under the microscope presents a number of irregular-shaped bodies approaching a round, oval, or triangular form, varying in their longest diameters from the 4th to the 6th of an inch. These bodies contain from one to seven granules, are unaffected by water, but rendered very translucent by the mercure. (Bennett.) These bodies are called tubercle-corpuscles, and are mingled with molecules and granules, in a greater or less number, according to the consistence of the tubercle. When the tubercle becomes hardened by calcareous deposits, few of these bodies are found in the mass, and the majority of the irregularly-shaped bodies of phosphate of lime, and crystals of cholesterol.

In the earlier stages of tuberculous deposit of the lungs, the system is found to contain small portions of the disintegrated tissue of the lung, and in some cases this appearance has been observed when no physical or other decided indications of tubercle existed.

3. Blood. In some forms of the disease the blood-cells exhibit a changed character, which can alone be detected by the microscope. This is seen most remarkably in a disease recently discovered by Dr. Bennett, of Edinburgh, called 'Leucocythermia,' in which the white corpuscles of the blood, which are much fewer than the red in healthy blood are found to be greatly increased in number. (Bennett, 'Diseases of the Skin.')

In many diseases the blood presents an unusual degree of thickness. In this condition the red corpuscles easily lose under pressure their rounded margin, and assume a cunoid or flattened shape. They do not aggregate together in the usual form of rolls, but present masses of an irregular shape.

In blood produced by internal hemorrhage the red cells readily break down and are partly dissolved. The liquor amnini and liquor albus have been observed to contain a large number of granules. In these conditions also the blood-cells frequently present nuclei in their interior.

Cholera the blood has been observed to undergo a remarkable change. As stated by Bennett, that in blood he examined the red corpuscles were paler than usual, the colourless ones were normal, and mingled with these were others which varied both in shape and size. The latter were generally circular, but some were oval and a few were irregular. The diameter of the corpuscles varied from the 6th of an inch, and their transverse diameter about the 6th of an inch.

In certain cases the serum of the blood presents a milky appearance, and on being allowed to rest a creamy pellicle is formed on the surface. These changes have not been observed in all cases, but it is found to be composed of minute particles of oil, which resemble the smaller molecules found in milk and the chyle.

The blood has been observed to undergo other changes, observable by the microscope, in conditions of plethora, fever, or acute inflammation. These changes have not been observed in all cases, nor have they been sufficiently accurately described to be relied on at present as a means of diagnosis.

4. Pus. It becomes sometimes a matter of considerable diagnosis to detect those cells present in the gland or in discharges from the human body, as when present they indicate the occurrence of suppuration, sometimes in parts of the body which cannot be observed. Normal or good pus, as it is called, consists of numerous corpuscles floating in a clear liquid. The corpuscles are globular in form, with a smooth margin and a finely granular surface. They are exceedingly like the white blood-corpuscles in their general appearance. They vary in size from the 4th to the 6th of an inch in diameter. They generally contain in their interior a nucleus, and are surrounded by a thin film on the addition of water, and the rough surface of the cell also becomes smooth. The nuclei are liberated from the cell by the addition of acetic acid, in the form of two, three, five, or more, each of different sizes. Occasionally the pus-corpuscles are surrounded by a second membrane. At other times they are not perfectly global, presenting a greater or less irregularity of their margins, and accompanied with granules and molecules. This occurs is pus from various ulcers and other kinds of what is called unhealthy pus.

5. Vomited Matters. It is frequently of importance to examine the matters thrown up from the stomach by vomit. The microscopic appearance of the microscope to these matters has been the discovery of a plant which has been called Sarcina Ventriculi. Occasionally other forms of plants have been found in the vomited matters, although these have probably been introduced from without. In cases where poisons have been taken which produce vomiting, the application of the microscope will detect the kind of poison. In this way the husks of the ripe fruit of the Deadly Nightshade, the seeds and leaves of Lobelia Medical, and other poisonous substances, have been discovered. It is also a matter of interest to ascertain the nature of the food taken by children or inconsiderable persons who can give no account of themselves, and this can be done by the examination of the vomited matter.

6. Feces. The contents of the bowels, when examined by the microscope, often afford important diagnostic indications. They contain naturally the matters secreted by the mucous membranes of the intestines and the remains of the food. They will also contain various morbid products. Amongst these latter may be mentioned plants and animals. Conferre and fungi have been found in the faces, and various organic bodies, now known to be introduced from without, were at one time regarded as the cause of cholera. The presence of pus- and blood-corpuscles may also indicate diseased conditions of the membranes of the intestines. In cholera the rice-water evacuations consist of mucus and the remains of epithelial cells. The nature of food of an injurious character may frequently be discovered, by the aid of the microscope, in the fecal matters.

7. Plants. The lower forms of plants, belonging to the orders Conferre and Fungi, frequently accompany diseases of the body. These are mentioned in the article Ecorrhiza, S. 5.

The most important point made out in the history of these creatures is that the eggs which they pass from one animal body to another, and that the whole group of what are Cystic worms but immature states of the more perfectly formed worms. The history of the common tape-worm (Tentia solium) of the human body may be taken as a type of the whole. The eggs of this worm are contained in the segments of the mature worm, which are called progloti- 

ides. These eggs, in order to their future growth and development, must be swallowed and submitted to a process of digestion by some other animal before they reach maturity. This process may occur in many species of animals, but that in which it takes place most commonly is in the pig. In the intestines of the pig the egg becomes an embryo, which is supplied with six hooks, by means of which it penetrates the tissues of the intestines, and during the blood-vessels is carried by the current of the blood to the various organs of the body. This embryo having reached a place of rest, is developed into the cystic worm known by the name of Cysticerium cellulotae. This form of the worm is well known, and produces in the flesh of the pig that appearance which is called in the markets "mealy pork." Here it remains and dies, unless the flesh containing it is eaten by some other animal. When eaten by man and submitted to the process of cystic worm, it is further developed. In the cyst there is a head called the "Scolex head," sup- 
plied with suckers and hooks, adapted to laying hold of the mucous membrane of the intestines, which, when effected, results in the growth of those segments which are known as the characteristic of the tape-worm. The scolex head is now the head of the tape-worm, and the segments are the proglot- 
ides which continues to increase, and eventually each segment is developed into a sexual being, containing both the male and female organs of generation, and the eggs are produced. These facts have been well established by expe- 
riments made by both Von Siebold and Kitchemeister. Man is also subject to the attack of cystic worms, Echinocoe- 
coccus, &c., which attain their mature development in other animals. The tape-worms of the lower animals have the same origin, and their history has now been traced in a large number of animals. Other forms of worms have been found to undergo similar changes in their larval conditions. The common fluke, which is sometimes found in the liver of sheep, commences its development from the stomach to the intestine Aescarii, being swallowed by fresh water mollusca undergoes a further development before it enters the stomach of the sheep, and becomes developed into the fluke in its liver. The Trichina spiralis, a little worm found in the intestines of a great variety of animals, is now believed to be the early stage of the growth of the Trichocephalus diopetr, a very frequent inhabitant of the intestines of man. The mature and immature forms of these worms found in man and some of the lower animals, are exhibited in the following diagram :—

[...]

The practical conclusion to which these researches lead, is the necessity of preventing the introduction into the system of Dysenteria E. V. of the future forms of these worms. The eggs of the various forms of tape-worms which produce the cystic states of the worm, are introduced into the stomach by water, salads, and all kinds of uncleanly food. The cystic worms themselves are introduced through the medium of raw and partly cooked flesh, especially pork, which should be carefully avoided.

PLATA, LA, STATES OF. [The historical notice of the Argentine Confederation has been brought down to 1856 (Plata, La) when Rossa had been created governor, or to be general-capitán, with almost dictatorial power. By this arrangement the provincial government of Buenos Ayres was invested with extraordinary powers, and temporarily charged with the transaction of all matters appertaining to the commonwealth, and the execution of the Confederation, being at the same time guarding out of its business with foreign nations. Rossa had previously served as governor and captain-general of Buenos Ayres for the usual term of three years, and had obtained univalved influences in that province, chiefly through his military powers, as displayed against the Indians. His decision and energy secured for a while internal peace, and the provinces began to recover from the effects of the long prevalent anarchy. But cruelty and despotism marked his sway at home and abroad, and it continually prompted him to endeavour to extend his influence and augment his power. The whole country, watered by the Plata and the Paraná, led him into disputes with foreign powers: and these ultimately brought about his downfall. His commercial policy had for its object to secure to the province the monopoly of the trade of the Plata, by a political policy to obtain a like territorial superiority. On the death of Francis, diezator of Paraguay, he refused to acknowledge the independence of that power, insisting that he should join the Argentine Confederation, and at the same time he resolved to allow the navigation of the Paraná by vessels bound to Paraguay. Lopes, the new dictator of Paraguay, therefore entered into alliance with the Banda Oriental, now called Uruguay, with which Rossa was at war. These powers applied for assistance to Brazil. The war was prolonged, and the country was in a state of confusion and the Paraná was in a state of blockade. On the earnest appeal of the merchants and others interested, Great Britain volunteered her mediation, but it was rejected by Rossa who marched his troops within a few miles of Monte Video, which was at this time the only place of blockade. The emperor of Brazil now interfered, and sent a special mission to request the intervention of the courts of London and Paris. The British and French governments in February, 1848, decided on sending envoys to the Paraguay, to place the three nations in a state of mediation, and to announce their intention to enforce a cessation of hostilities if needful, by an armed intervention. The offer was rejected by Rossa, but readily accepted by his opponents. The united fleet of England and France at once commenced operations by seizing the fleet of Rossa which was blocking Monte Video, and the island of Martin Garcia which commands the entrance of the Paraná and the Uruguay. The harbour of Buenos Ayres was at the same time the object of the war. Rossa had caused the entrance to be prepared to open the Paraná and convoy as far as Corrientes any merchant vessels that might desire to ascend that river. Rossa on his part had made haste preparations to intercept this fleet by planting batteries with parks of heavy artillery at Pointe D’Honneur, and in level with the river, supported by 24 vessels and 10 fire-ships. On the 19th of November, 1845, the combined fleet consisting of eight sailing and three steam vessels forced the passage with trifling loss to itself, but entirely destroying the batteries, and이며 the passage of the river. On the return of the fleet, with a convoy of 110 vessels, it was encountered at San Lorenzo by a very powerful battery which Rossa had erected in an admirable position, in the full expectation of destroying the enemy, and as a means of rendering the capture of the river, supported by 24 vessels and 10 fire-ships. On the 19th of November, 1845, the combined fleet consisting of eight sailing and three steam vessels forced the passage with trifling loss to itself, but entirely destroying the batteries, and overrunning the army of Rossa. On the return of the fleet, with a convoy of 110 vessels, it was encountered at San Lorenzo by a very powerful battery which Rossa had erected in an admirable position, in the full expectation of destroying the enemy, and of marking the capture of the river, and the surrounding country. The battery commanded the river, and was difficult of attack by the steamer, but it was speedily silenced by a rocket-boat, which had been the previous night secretly landed on a small island in the river. The combined fleet escaped with trifling loss, the rocket-boat lost not a man; but four of the merchant vessels with which, through unskilful piloting, ran sabores, were burnt to prevent them falling into the hands of Rossa. The loss to the Argentine army was very great. Again plenipotentiaries were sent out by the combined powers, but Rossa refused to yield, and England withdrew from the blockade in July, 1848. It was however continued by France until January, 1849. On the final withdrawal of the two great powers in 1849 there commenced a new period of active interference. The country of Rossa, essentially despotic, and devoted to the maintenance of the supremacy of Buenos Ayres, had moreover become intolerable to the provinces which desired a federal form of government. Accordingly, towards the close of 1848, Brazil, Uruguay, and Paraguay entered into a treaty, to which Corrientes and Entre Rios, as represented by General Urquiza, became parties, by which they bound themselves to continue hostilities until they had effected the deposition of Rossa, "whose power and tyranny," they declared to be "incompatible with the peace and happiness of this part of the world." Early in the spring of 1851 a Brazilian fleet blockaded Buenos Ayres, and soon after an Argentine army commanded by Urquiza crossed the River Plate. The struggle was long. General Urquiza, after deposing Rossa, commanded the army of Rossa in Monte Video, made a show of resistance, but it was merely to gain time in order to complete his arrangements with Urquiza, and he soon after capitulated. His forces, numbering 70,000 men, crossed into Buenos Ayres. A general engagement was fought on the plains of Moron, February 9, 1851, when the army of Rossa was entirely defeated. Rossa, who commanded the army, attempted to escape by crossing the river, succeeded in landing on the opposite bank, and in the dress of a peasant, he reached in safety the house of the British minister at Buenos Ayres. From thence, with his brother, he proceeded on board H. M. steamer "Rattlesnake," on the 10th of February sailed in the "Rattlesnake," on the 10th of February sailed in the Conflict steamer for England. But the fall of the tyrant did not bring peace to the unhappy country. Urquiza, by the governors of the pre-
PLA 515  PLU

Vinces assembled at San Nicolas, was invested with the
chief post, and appointed Provisional Director of the
Argentine Confederation. The Congress of Buenos Ayres, however, declared against him, and pro-
tested against the proceedings of the convention, on the
ground of the superior privileges of Buenos Ayres being
meracned. Urquiza died 1853; 1-2, orthodox; suspended. Nuts elevate, with a persis-
tent style. Seeds usually solitary and albaceous; radicle
inferior. They are natives of the Levant and North America
northward. They are tree plants, but their timber is not
endurable. There is but one genus (Platanus) in the order and six species. [Plana.] The family resembles Arceaeoideae and
Althaeae.

POTYSTERON. [Tomatoes.]
PLEASING, AT LAW and IN EQUITY. Although
modern Statutes have made several alterations in the pro-
cedure of the Superior Courts both of Law and Equity, the
outline of the system prevailing in the Courts of Com-
mon Law, which is here described, in Plummer's
System, xviii, p. 245, et seq, is still substantially accurate. The more important changes
affected in the procedure of the Common Law Courts have
been mentioned under ABETMENT [S. 2], INTUITION [S. 2], and MANDBANUS [S. 2]; those in the Court of Chanery
under Equity [S. 2]. It may be added here that the system
of pleading devised for the new Courts of Probate and
Divorce, is of the nature of that now in use in the Courts of
Common Law.

PLAGA, a genus of Plants belonging to the alliance
Aglaia, the order Coraceae, and the sub-order Sphaero-
cocceae. One of the species, P. Helminthocorrum, is called
Coriscan Moss, and has a considerable reputation as a ver-
montal remedy for liver and indigestion.

PLUMBO-CALCITE. [Mineralogy, S. 1]
PLUNKETT, WILLIAM CONYNOHAM, first LORD
PLUNKETT, of Newton, County Cork, was the second son of the
Rev. Thomas Plunkett, a Presbyterian minister at Ennis-
killan, in which town his son William was born in July 1764.
Having some scruples as to the received doctrine of the
Trinity, the elder Plunkett removed to Dublin, where he
became minister of the Strand-street chapel. His eldest son
practised for many years as a physician in that metropolis,
and bequeathed to his brother a large library and a consider-
able fortune. William was still a boy when his father died,
leaving the care of his family to the piety and zeal of his
congregation. His dying request was not in vain, and the
sacred administration of the Christian mysteries was
sent to Trinity College, Dublin, where he obtained a scholarship and a degree, and where he was the friend and
contemporary of the late Dr. Magee, archbishop of Dublin.
Mr. Plunkett was called to the bar in 1797. He had already
gained some reputation by his speeches delivered in the
debating club of the university, then known as the Historical
Society; and the late Earl of Charlemont soon afterwards
introduced him into the Irish Parliament, as member for the
brave. Mr. Plunkett commenced his public career by bold and
sarcatic oratory, reserving himself almost entirely for great
occasions. Hence his name is but little associated with the
every day business of legislation; the fame which his
speeches in the House of Lords have acquired is but little connected with the seal with which he opposed the legislative
Union in 1800. The vehement oratory with which he de-
ounced the ministry on this occasion, proved the means of
increasing his professional engagements in the Irish courts of
law. His reputation for eloquence and acuteness was not
repaired, with liberal interest, the contributions of his father's
congregation which had been the means of enabling him to
get a start in life. About the same time he married Cath-
erynna, daughter of Job O'Sullivan, Esq., who had repre-
sented the county of Donegal in Parliament. When the rebellion of 1798 broke out, Mr. Plunkett gave the aid of his professional talents to its victims, and indeed was at one time so intimate with Robert Emmett and his associates, that he was moved to make this public observation of
being concerned in their unhappy proceedings. The accu-
sation however was shown to be unfounded.

In 1803 he was appointed solicitor-general for Ireland, from
which he was removed in 1810 to that of attorney-
general. In the following year, he was appointed Solicitor-
with his son at the head, into office, and he determined to
throw in his lot with them. Accordingly he retained the
attorney-generalship under their administration, whose well-
known views offered an opportunity for the Catholic Asso-
ciation to press upon them the notice of granting Roman Catholic emancipation. Of this subject, Mr. Plunkett
never was an easy and energetic advocate. The death of Mr.
Fox having broken up the Graveline administration in 1807,
Mr. Plunkett, back in the good graces of his friends, pursued
his chancery practice with such success, that for several years
he was engaged as leading counsel in almost every important
Irish chancery suit, and rapidly accumulated a large fortune.

Mr. Plunkett first entered the British House of Commons in
1807 as member for Midhurst. In 1812 he was elected to represent the University of Dublin, which at that time
returned only a single member; and he was re-elected in
1818. On his first speech in the House of Commons he
at once secured for him a high reputation, Mr. Canning
affirmed, that it brought back the days of Burke and Pitt,
of Fox and Sheridan. In 1822 a number of ministerial
changes took place in Ireland, the Marquis of Lond-
onderry, and among others Mr. Plunkett, was appointed
attorney-general for Ireland, the late Marquis of Wellesley
being lord-lieutenant, and in that capacity he was engaged to prosecute on behalf of the crown a large number of the
Dublin Orangemen, and of the insurgents in the south of
Ireland. Early in 1837 Mr. Canning proposed to appoint Mr.
Plunkett master of the rolls in England, but the intention
was ultimately abandoned. In the following June however he
was elevated to the post of lord chief-justice of the com-
mon pleas. He assumed the duties of the judicial reform
which was to be one of the most momentous events to call forth. But it was otherwise in the English
House of Lords, where he sat by the Duke of Wellington, at
his Grace's special request, to advise with him at every step
of the Roman Catholic Emancipation Bill, of which he ' took
charge' in its passage through the Upper House.

With the passing of this measure the political career of
Lord Plunkett may be said to have closed, though he was
appointed Lord Chancellor of Ireland by the ministry of Earl
Grey at the close of 1830. This post he occupied for eleven
years, with the brief interval of a few months in 1834-36,
during which the seals were held by Sir Edward Sugden
(now Lord St. Leonards). He ultimately only resigned the
chancellorship a few months before the removal of the Liberal
ministry. The liberal measures of that administration
he was induced to resign in order to make way for Lord
Campbell. During his later years Lord Plunkett had almost
wholly retired from political life, and indeed for several years
before his death he had not come over to England to take
his seat in the House of Lords, but spent his declining days
in the enjoyment of the society of his family and private
friends, at his country villa near Bray, where he died on
the 4th of January 1854. His eldest son, now second Lord Plun-
ket, is also a person of note.

On the whole, nature was bountiful to Lord Plunkett, and
accident favoured him at almost every step of his long and
brilliant career. He was sixty-six years of age when he took
his seat in the Irish Court of Chancery, and it could scarcely
be expected that he should not have obtained some share of
his previous fame. His reputation shot upwards from a narrow
ground-work. His speeches were at once few and famous;
more striking instances of perverted talent, and personal advantages thrown away, than that of Edgar Poe. Two small volumes of tales and one of poetry, besides the 'Eureka' already mentioned, are all that remain of him.

POLAND. The Empire of Russia, by a ukeu, dated August 2nd, 1862, to President Maciora, President of Congresses, exclusive of the city of Warsaw, which are governed in the same manner as the other provinces of the empire, each having a military and a civil governor. The following table shows the area and population of the present divisions according to the official returns for the year 1861:

POLAR COUNTRIES AND SEAS. The countries and seas which lie between the northern coasts of America and the North Pole are noticed in the article NORTHERN WEST PASSAGE, S. 2; those which are situated on the other sides of the North Pole are described under their respective names. The great American ice front in the Arctic Ocean is the subject of the article AMERICA. [For NORTHERN PASSAGE, S. 189, and AMERICA.] It only remains to notice certain conditions of the countries and seas which surround the North Pole. The discoveries which have been made in the seas surrounding the South Pole are narrated in the article SOUTHERN POLAR COUNTRIES.

The seas which surround the North and South Poles are named the Arctic Ocean or North Polar Sea, and the Antarctic Ocean, or South Polar Sea. The two oceans are bounded by two large archipelagos which are separated at about 66° 30' N. lat. and 66° 30' S. lat. At the Poles themselves there is only one day of six months, during which the sun never sets, and one night of six months, when the sun never rises. In the spaces comprised between the Polar Circles and the Poles the quantities of continuous day and continuous night vary according to the distances from the Poles. Thus, at the north point of Nova Zembla, 75° N. lat., there is uninterrupted light from May 1st to August 12th, and uninterrupted darkness from November 8th to February 15th. At the Arctic Circle, the extreme northern point of Greenland, and at the North Pole, the sun is 24 hours above the horizon; and the reverse at the South Pole.

The Polar Regions arise from the sun's rays striking the earth obliquely, as at the equator the heat is produced by the sun's rays falling upon the earth vertically.

The two great continents of the Northern Hemisphere terminate towards the North Pole near 70° N. lat., which probably may therefore be considered as the general boundary-line of the North Polar Sea. The lands comprised within this polar basin, besides the northern shores of Europe, Asia, and America, include the part of Greenland and Nova Zembla, the islands of Spitzbergen, the Lofoten Islands, and the great mass of islands which lie opposite to the northern coasts of British America. The North Polar Sea has only one entrance from the Pacific Ocean, by Behring's Strait, the narrowest part of which, between East Cape and Prince of Wales Cape, is only about 18 miles across. From the Atlantic Ocean, besides the great entrance by Spitzbergen Sea, it is now known that there are entrances by Smith's Sound from Baffin's Bay, and by the Wellington Channel from Barrow's Strait.

A large portion of the Arctic Ocean is constantly filled with extensive fields and moving masses of thick and impenetrable ice. This portion seems to extend round the Arctic Circle, where it is divided by the submarine barriers of Novaya Zemlya, the northern part of Greenland, and the Lofoten Islands. In an easterly direction it extends from the north point of Nova Zembla to the western side of Melville Island. Here the navigation westward up Barrow's Strait ceases, the 'pack-ice,' as it is called, pre-
senting an impassable barrier. On entering the Arctic Ocean from the Pacific through Behring's Strait, the most daring and skilful navigators have not been able to penetrate much farther in a northerly direction than 70° N. lat. Captain Cook, in his last voyage, after passing through Behring's Strait, sailed as far westward as North Cape, 180° W. long.; but here the masses of ice prevented any farther advance. If the navigator, after passing through Behring's Strait, turns eastward and proceeds towards Spitzbergen, he passes through Terra Nova, the bread and the pack-ice, a narrow passage, much encumbered with broken ice, and may thus with some difficulty reach the most north-eastern point of the American continent; or, having reached Baring Island, may turn northward and try to advance towards the Polar Sea by following either of the tracks of Captain McClure.

The great entrance to the Arctic Ocean by the Spitzbergen Seas is not attended with much difficulty. Ships sail every year from the shores of the Atlantic Ocean to Archangel, and must necessarily pass round North Cape, 71° 10' N. lat.; other vessels proceed annually to fish for whales, which they never expect to take south of about 70° N. lat.; and others much smaller go every year from Hammerfest and other places to fish for walruses along the western shores of Spitsbergen. Barents, the Dutch navigator, in 1594 and 1596, traced the western shores of Nova Zembla as far as North Cape, 70° N. lat.; and the Russian navigator Ziwolks, who in 1636 surveyed the island of Nova Zembla, found no difficulty in sailing around Cape North, 70° N. lat., to the eastern coast at 61° E. long.; but impenetrable masses of ice prevented his advance farther to the east.

The greater or less severity of cold in the Arctic Seas appears to depend upon the degrees of latitude. Thus, on the European side of the Polar Basin, the navigation, as has been shown, is open as far as 80° N. lat.; on the Asiatic side it is generally closed by masses of ice; on the American side the cold is very severe, and the navigation is entirely shut out, and in many parts dangerous. At North Cape, in Europe, 71° 10' N. lat., the mean temperature of the year is 32° Fah.; at Bear Island (Cherry Island), between North Cape and Spitzbergen, 70° 45' N. lat., it is 38° Fah.; but opposite the coasts of Siberia, farther to the east, the floating masses of ice render the navigation so dangerous that some of the ports of the line have not been surveyed. This tract includes the most northern point of Siberia, Cape Severo (Severo Vostochinni Nosi). In this part of the Polar Basin are the Liakhov Islands, the largest of which are named Kotelnof Fadiseifako, New Siberia, and Liakhov. They are situated between 73° and 76° N. lat. On these islands the snow does not entirely melt even in summer, and there is no vegetation whatsoever. It is not to be wondered at that in winter the large body of the sea is free from ice at certain distances from the shore. North of New Siberia and Kotelnof the distance is less than 20 miles. Farther eastward, near Wrangel Island, the distance is about 170 miles distant; but between 175° and 180° E. long., opposite Cape Yakan, it is only about 4 miles distant. At Ustyanik, in Siberia, near the mouth of the river Yana, 70° 55' N. lat., the mean temperature of the year is only 4° Fah. At Winter Island, on the north-eastern coast of America, in 66° 11' N. lat., 83° 30' W. long., the mean annual temperature is not more than 7° Fah., while on the south shore of Melville Island, about 74° N. lat., the mercury of the thermometer is frozen every winter during four or five months.

That there is a great sea comparatively unincumbered with ice in the vicinity of the North Pole, and perhaps flowing over it, seems to have been rendered probable by many facts and circumstances. Barents, in 1594, remarked, "as soon as we made from the land [Nova Zembla] and put more into the sea, although it was much farther northward, presently we felt more warmth." Captain Parry, in his attempt to reach the North Pole in 1857, leaving his ship, the Hecla, marooned on the fast ice, was able to proceed with his party over the ice, dragging the boats and sledges which had been constructed for the purpose. On July 27th they reached 85° 45' N. lat., 19° 35' E. long., when they descended the island, and the next morning took the ice over which they were travelling northward was itself drifting southward, they relinquished their attempt, and commenced their return-journey. On August 12th they reached Little Table Island, or rather a rock north of it, which Captain Parry named Rose's Isle, and which is the farthest land known in the northern hemisphere; it is in 80° 47' 30" N. lat., 20° 34' E. long. Captain Parry and his party were absent from the Hecla 61 days, the distance traversed being 324 miles. On July 16th, being in 88° 17' N. lat., it raised incessantly for 31 hours. On July 16th the temperature was 37° Fah. in the shade. "In the evening it was so warm in the sun, though the temperature in the shade was only 35°, that the tar was running out of the seams of the boats." This great open sea is not a great distance when they were farthest north. After the middle of July no ice entered the bay where the Hecla was moored, and for some weeks afterwards not a piece was seen in the vicinity.

In further confirmation of there being a great sea in the vicinity of the North Pole, it may be stated that Sir Edward Belcher saw an extensive sea with little ice north of the Wellington Channel, as did also Captain Penny north-west of the Victoria Channel; that Captain Inglefield saw that sea north-east of Whale Sound, near the head of Baffin's Bay, and also north of Smith's Sound, which is an outlet into the Polar Basin from the head of Baffin's Bay. The same extensive open sea was seen by Dr. Kane from a position still further north of Smith's Sound than that which was attained by Captain Inglefield.

The difference of temperature between the north-western shores of Europe and the north-eastern shores of America is owing to two main causes—the Gulf-Stream, and the drifts of the ice masses from the Polar Basin. The Gulf-Stream is a great warm current many miles in width, which flows in a north-eastern direction from the Gulf of Mexico across the Atlantic, and passing by the British Islands, north of the Polar Basin, reaches the Polar Sea as far as the northern shores of Spitzbergen and Nova Zembla. Here in the spring it meets the powerful current caused by the breaking-up of the ice in the great rivers of Siberia. As this vast body of water and broken ice advances towards the shores of Nova Zembla and Spitzbergen, the Gulf-Stream opposes its farther progress south and gives it a direction westward, so that it passes by East Greenland and Iceland, and reaches the shores of America and New-Foundland, in 60° W. long. and 60° N. lat. (in length and of great thickness) descends in the spring as low as 40° N. lat. On the coast of Norway, on the contrary, as far as 71° N. lat., not a piece of drift-ice is ever seen.

The countries which surround the North Pole generally afford an abundant supply of animal food, consisting of the walrus, the polar bear, the moose-deer, the rein-deer, the wolf, the polar hare, and the seal. The number of aquatic birds is very large, and various kinds of fish are in great abundance.

POLEVY, NIKOLAY ALEXIEVICH, one of the few distinguished authors whom Siberia has yet produced, was born on the 22nd of June (old style) 1796, at Irkutsk. His father, who was a merchant, settled for some generations at Kurak, where the names of Polevoy and Golikov are excessively common, had been left an orphan at the age of thirteen, and sent to Tobolsk in the employ of a relation of the name of Golikov. Most of the elder Polevoy's life was spent in commercial enterprizes in Siberia, and at one time he had the prospect of making a fortune by establishing a new company for commerce with Russian America, but the union of the two old companies, which had taken place in 1808, he set up a manufacture of earthenware at Irkutsk, and "he used," says his son, "to pronounce with enthusiasm the name of Wedgwood." In assisting in the business of this manufactory, and of a brandy distillery with which his father was also connected, the early years of Polevoy were passed. He never apparently received any schooling; he seemed to read from an elder sister at six years old; at eight he used to read aloud to his mother novels, and to his father the Bible, and the 'Moscow News,' and the Fateshekov newspaper; and amused himself by composing a manuscript of a paper (in imitation of the 'Moscow News' ['Monokovskii Vedomosti']), which he called the 'Asiatic News' ('Asiatskii Vedomosti'). The father was in the habit of boasting of his relation to the history of Peter the Great in thirty volumes, and the boy formed the singular project of writing additions to a work already so voluminous. He also tried his hand at composing plays, and produced a drama, 'The Marriage of the Tsar Alexis Mikhailovich,' and a tragedy, entitled 'Blanche of
Bourbon. "At last," says Polevoi in the autobiography prefixed to his 'Ocherki Rosskoi Literatury,' published in 1839, "I became more interested in the history of my country, and, of letters and history, for my memory at that time was such as I have never met with in anybody else. To learn by heart a whole tragedy cost me nothing. In a word, if I must describe
my mental progress up to the year 1811, it was this: I had read about all that was published, and I knew and remembered all that I read from the verses of Karamzin, and the articles in the 'Courier of Europe' (a Russian Magazine), to the Chronological Tables and the Bible, from which I could repeat whole chapters by heart. I was known in the town of Irkutsk, and I was a good talker. I was the first and only Russian
agent of his quitting Irkutsk, passed through all Siberia, saw a play for the first time at the theatre of the great Makariev, and on his arrival at Moscow spent much of his time at the theatre and the bookshops, wrote tragedies and romances, and was unwillingly recalled to business and the brandy distillery by the arrival of his father. This took place in June 1812, and both business and pleasure were soon at an end in the devoted city, where the configuration was familiar, and he was fugitive from before the army of Napoleon I. For a few weeks after this Polevoi was almost in constant movement from St. Petersburg to
Irkutsk, and from Irkutsk to Kursk, and his literary ardour, deadened by the reproaches of his father, who now wished him to return to Moscow, and the losses and debts of his parents, was extinguished. It suddenly revived when he was about eighteen, a clerk at Kursk; but the main cause of its renewal, according to his own account, was his discontent with his then situation and its limited prospects, and his conviction that in Russia there was no other way to consideration for a poet except in his position but through learning and literary success. Himself and his younger brother, Xenophont, began to study French and German in secret, devoting many hours of the night to these studies. He took up 'Imitation of Jesus Christ,' and began to bring it into a new world of reading. In 1817, when the Emperor Alexander paid a visit to Kursk, Polevoi sent to the 'Russian Courier' an article describing the event, and had the pleasure of seeing for the first time his name in print. Other contributions followed, and the name became known; on a visit to St. Petersburg he was introduced to Zhukovsky, Gribboyedov, Grech, and Bulgarin; and in 1826 he commenced at Moscow the publication of a magazine entitled the 'Moscow Telegraph.'

For the twenty-one years that followed, Polevoi was in incessant literary activity. The 'Moscow Telegraph' soon made itself conspicuous by the vigour and spirit of its remarks on the literature of the day; the example was extended to other Russian literary reviews. The new era in criticism from the articles of Polevoi. It was naturally supposed that the editor had little spare time at his disposal, but the public was surprised to hear in 1829 that he had completed a history of the Russian nation, in 12 vols., containing a continuous narrative from the earliest times to the reign of the Emperor Nicholas. The early volumes of this history were assailed without mercy by many who were astonished at the presumption of its author in measuring himself with Karamzin, and of the twelve volumes only six appeared in print, the last in 1833. Possibly its further progress may have been checked by the censorship, as the 'Moscow Telegraph' was thought too liberal in its tendencies, and opposed to the Russian government. This was in or about 1835. Polevoi removed to St. Petersburg, and his activity, instead of slackening, became greater than ever. In "Moscow," says Nikitenko, in an article on his work in the 'Biblioteka diya Chteniya' for 1846 (vol. lxxvi.), "Polevoi was a journal, an historical and romantic-writer. In St. Petersburg he was both an editor and reader, contributing to several journals; he composed romances, tales, essays, translations from Shakspeare, and such a multitude of dramas, tragedies, comedies, vaudevilles, national farces, and so on, that criticism from abroad was astonished at the number and bulk of his productions, the variety of their character, or the rapidity with which he threw them off." The natural result of the name of Polevoi, which at one time promised to be one of the brightest in the Russian literary horizon, lost much of its luster. For the last ten
years of his life his reputation sunk instead of rising. He died at St. Petersburg, on the 2nd of February 1846 (a.s.), leaving his father and three medical attendants that his constitution was completely worn out by his incessant literary labors. He died in poor circumstances, and left a large family.

The most interesting work of Polevoi is perhaps his 'Ocherki Rosskoi Literatury,' 'Sketches of Russian Literature,' 5 vols. St. Petersburg, 1839. It consists of reprints of select critical articles which had appeared in the 'Telegraph' and elsewhere, on Dovzhavin, Karamzin, Pushkin, and other of the most eminent names in Russian literature. The complete edition of 'Stroitsy i lavki,' 'Government Work and Translation' of N. A. Polevoi ('Dramatischesschi Sochneniya i Pervovodi,' 4 vols., St. Petersburg, 1842-43, comprises only the more popular of his productions, several of which enjoyed a great success. In particular his 'Grandfather of the Fleet' ('Diedushka Rosskogo Flota'), founded on the history of the old boat which bears that name, which Peter the Great took as the model for his ship-building. The author's favourite, as he tells us himself, was 'Parasha Sibirevschina' ('Parasha the Siberian Girl'), founded on the same historical anecdote which supplied Madame Cottin with the ground-work of 'Elisabeth, or the Exiles of Siberia.' In another play, 'Boldatkovskoe Sredstvo' ('A Soldier's Heart'), he has made the most of his knowledge of the conditions of life in whose life it is founded. Polevoi's translation of 'Hannet,' which was produced at Moscow in January 1837, is unusually close to Shakspeare; not even the scene of the grave-diggers is omitted, and the dialogue passes from blank verse to prose, the same limitations of time that limit Shakespeare being far from successful. His 'Life of Suworov,' or Suvorov, is a very popular book in Russia. His 'Life of Peter the Great' (4 vols., 1843), is the best biography of that wonderful man the Russians yet possess, and superior beyond all comparison to the tedious compilation of the author's kinsman Golikov. His 'Life of Napoleon' (6 vols.) was only brought by himself to a point a little beyond the confugration of Moscow, and was finished after his death by his brother in-law, 'Ataman G. Golikov,' who states that the work was finished at Kharkov, where Golikov was Russiani's Secretary, and that Golikov's son, the 'Ataman,' who was at Petersburg at the time, was engaged in finishing the work. This conclusion of this work, 'is not a shapeless mass like the Roman empire, not violently put together like the dominions of Napoleon, not scattered over the whole world like the British sovereignty, the three examples of vast empires common to European people.' Russia was a nation, it is Russiani, but it is not Russia," or an historical picture of Russia from 1746 to 1846 (9 vols., 1845), is perhaps the least satisfactory of his historical works, but it contains passages of interest to a European reader.

Though the 'Moscow Telegraph' was suppressed in Polevoi's hands, and its author is spoken of by Hertzen as having the reputation of a decided liberal, his patriotism as a Russian is one of the qualities which most forcibly strike the reader at his death. "Polevoi," says his biographer, "was a Russian man. After all from the original elements of the Russian empire, the Russian mind and the Russian soil, that Peter the Great reconstructed Russia. He still remained a Russian sovereign, and his subject, though fromerwise with the German, remained a Russian man. With his decided tendencies towards western Europe, it is impossible that something supernatural should not find admission, that traces of it should not remain till even now, but they are perishing and will perish, as the Gallicisms die out of our Russian tongue." And sixty millions of a nation like this, fastened together by one glue, inspired with faith in that power, are directed by a single will, on lines which will not these sixty millions do? The future belongs to us. Whenever else comes the fear with which we inspire Europe and the West, the fear from which it strives to remove us, then we come against this darkness as nothing but the rise from a consciousness which is not the consciousness of strength, from a feeling different from that of hope in the future, on which we Russians look with such boldness and such faith.

The establishment of a police force all over England has at last been made compulsory by the Statute
POLISHING SLATE. [MINERALOGY. S.1]

POLPERRO. [CORNWALL]

POLYergus, a genus of Formicidae, separated from Formicini in 1822. A peculiar species of the Amazon Ant. The species are destitute of stings, and have the antennae near the mouth and the mandibles narrow, curved, or very much hooked. The habits of the Amazon Ant, P. recurvea, are very remarkable. The neuters of this species are often carried in the nest of the ant, war upon the neuters of other species of Formicidae, especially C. curvilineus and F. fusca. The result of the conquest is the making slaves of the latter, who are always found doing the hard work of the colonies of their enslavers. [Art.]

POLYPTERUS, a genus of Fishes belonging to the family Clupeidae. The sides of the upper jaw are immovable; the head is covered with sharpened bony plates; the body is silvery, the scales separate fins on the back; the teeth like a rasp, with long ones in front; the stomach large; a double air-bladder, with large lobes, the left one opening freely into the gullet. There are two species; one found in the Nile, the other in the river of Hong Kong. The neuters can produce a number of living representatives of a large family now extinct. They belong to the large division of extinct fish called Sauroïd, on account of their resemblance to the Lizard tribes.

POLYZOA, frequently termed Bryoza, the animals belonging to the Molluscan Steinkircher, closely allied in some respects with the Tunicata, and especially with the Phyllognatha, especially with the Mucronata, whilst in others they approach the Branchiopoda.

The analogies presented in their structure with that in other Molluscan groups having been pointed out in the article Mollusca, S.3, it will be needless here further to refer to them. The present article, after giving a brief view of the more important structural peculiarities of the class, will be devoted more especially to their mode of classification; but since the term Polyzoa, here employed, has by no means obtained universal adoption, it appears requisite to say a few words explanatory of the reason why we have introduced it is the purpose of the present work.
Month, or that opening, as it may be termed, through which the polypide makes its exit and its entrance. The borders of this opening are sometimes furnished with Oral Spines, and it is sometimes closed when the creature has retreated into the cell, by a Crescentic Lip, usually having a cartilaginous base (fig. 6a). In many cases the wall of the cell is of equal thickness and similar structure throughout, but in the Cheilostomatous sub-order the front of the cell, or that side upon which the mouth opens and the animal comes out, very often differs from the rear. Upon this side, the thickest, a greater or less extent of the front may remain wholly or in great measure membranaceous, as in the genus Membranipora (fig. 14); or be filled in by a sculptured or perforated calcareous plate (Cerithium, Leporina, fig. 15), and many others. The space thus defined when left membranaceous (as it appears in most if not all cases to be at an early period in the formation of the cell), is termed the Aperture. The borders of the aperture are sometimes furnished with Marginal Spines. In some instances, as in Cabearea and Scrupocellaria (sp.), the aperture is protected in front by a curious outgrowth from near the margin, which is termed a Pedunculate Operculum. The back of the cell is that part, of course, which is opposite to the front; the mouth is situated at or near the upper part of the cell, and is either terminal or subterminal. Other parts, which may be regarded as appendages to the cells, but which are not universally present, are certain organs, either of offence, defence, or both, as the well-known Avicularia, a form of the avicularia, or a form of a avicularia of a pinch, of the ossicles, or the sponges constituting a long, slender, moveable sets. However diverse in appearance, these two kinds of organs are all constructed upon the same general type; that is to say, the organ consists of a hollow tube, or tube, and in the latter the analogous organ seems to represent a metamorphosed cell, and in situation corresponds with the other cells of the polypide.

The importance of the avicularian and vibracular organs, in a systematic point of view, may be estimated from the circumstance that, out of 36 genera of Cheilostomatous Polyzoa, 20 include species armed with one or the other, or with both; and that of 101 species no less than 120 are so furnished. They appear to be confined solely to the Cheilostoma.

In many cases the polypide is affixed by numerous slender corneous tubes, which seem to be merely subserous to that portion of the polypide which is the true stalk. The Polypide, or colony itself, is formed of an aggregation of cells, which throughout the two former orders of the class as here arranged, arise one from another, either singly or in pairs, from each cell (fig. 15a), which represents the beginning of the polypide of Leporina ciliata, and from various parts of the cell, as on the back or sides, near the top or not far from the bottom. And it is to the variety of modes in which the cells arise that the diversity of form of the polypide is due. In one division of the third sub-order, the Cheilostomatous, the cells do not arise in this manner, but from a tube common to several cells, and which is either divided or not into distinct intermedium. This portion of the polypide is termed the Basal Tube.

Having thus defined most of the terms which it is necessary to employ for the purposes of classification, we will briefly describe the anatomy of the various parts of the animal in the order in which it is given by Professor Allman.

Organs for the Preservation of the Individual.

A. Dermal System.

The Polypide is formed of a number of little chambers, or cells, each of which contains a polypide, and consists of two portions—an internal tunic, soft, transparent, and contractile (the Endocyst), and an external investment (the Ectocyst). The endocyst lines the interior of the cells and when it arrives at their orifice would protrude beyond the ectocyst, were it not that here it becomes invaginated, or inverted into itself, and then terminates by becoming attached round the base of the tentacular crown; during the exertion of the polypide it undergoes eversion, sometimes complete, sometimes incomplete. The endocyst consists of a thin, firm layer of gelatinous tissue (fig. 6b) and the polypide is suspended, surrounded by the perigastric space. These sacs are all closed above where they are attached to the polypide, and below, in some cases, their cavities are in communication with those of the neighbouring sacs (or with the stomach itself). The cavities of the ectocyst, however, are not connected.

The ectocyst and endocyst represent respectively the external and middle tunics of the Tunicata, or the mantle and shell of other Molluscs.

The Endoderm is a simple thin and membranaceous, and often contains transverse muscular fibres. A portion, perhaps the whole, of the inner surface is clothed with vibratile cilia. The ectocyst varies greatly in composition and aspect. Throughout the greater number of the Polyzoa it is hardened by the deposition of calcareous matter, whilst in many others it is horny and flexible, and in some even of an almost gelatinous consistence. In the P. hippocrepis it is in most species composed of a tough peramentaceous brown membrane, strengthened by the deposition of irregularly formed siliceous particles, sometimes rendering it quite opaque. In other cases again, as in the genus Angiostoma v. Bem., the soft and flexible, and as it were florolcetous ectocyst, is pervaded by aluminous and siliceous particles, and the same is true of the outer layer of Ctenostomata. In Ostracida and Polycystina the ectocyst would, at first sight, seem to be entirely absent, and the cell to be composed exclusively of the endocyst. Careful examination however shows that both are present, and that the ectocyst consists of a lining of organous and transparant, usually free from any earthy deposit. In some instances, and very distinctly in the Solenaridae, or Luniulites, the surface of the calcareous ectocyst is further covered with a thin horny pellicle, apparently resembling that on the shells of many Molluscs.

B. Organs of Digestion.

These consist of an alimentary canal, commencing at the mouth and terminating at the anus; and subdivided into several portions, which have received the same names as those of the apparently corresponding parts of the alimentary tract in the higher animals. The mouth is edentulous and usually unarmed, though sometimes (as in the proper P. hippocrepis) furnished with a valve-like organ of very peculiar formation, and which is considered by Professor Allman to be analogous with the 'langue' of the Ascidians.

From the mouth an osophagus, or pharynx, leads downwards into a tube, the intestine, in some cases furnished into a sort of gizzard, which in that genus is armed on each side with a serrated tooth. The stomach is a thick walled sac, which in most cases dilates inferiorly into a rounded or more or less pyriform cavity, from which is derived the pyloric orifice.

The pyloric orifice is distinctly villous, and is furnished with prominent lips, which project into the intestine. The intestine, wide at the origin, rapidly diminishes in diameter till it terminates at a distinct anus near the mouth. The liver is represented by spherical corporaces of a brown colour, seated on the wall of the stomach. The mouth and upper part of the osophagus and the commencement of the intestine, are, in most cases, at any rate, furnished with vibratile cilia.

C. Organs of Respiration and Circulation.

Upon the tentacular crown and the walls of the perigastric space, which corresponds with the 'sinus system' of the Tunicata, would seem chiefly to devolve the function of bringing under the influence of the gastering medium the nutritive fluid of the tissues.

The tentacular crown of a Polyzoan consists of two portions: 1. a sort of stage, or disc, which surrounds the mouth (fig. 15d); and 2. the lophophore, which are born in an uninterrupted series round the margin of the lophophore. The lophophore throughout almost the entire class is orbicular or annular; but in the Hippocrepis it is not as a rule orbicular, but consists of two triangular lobes, or arches, so that in that order it exhibits the form of a deep crescent. This condition of the lophophore is found in no marine species, and in Fredericia, a fresh-water form, the arms of the
crescent are obsolete, and the lophophore might, on a superficia
view, be regarded as orbicular; but a careful exami
nation, Professor Allman goes on to say, will render manifest
its departure from the orbicular form, the side corresponding to
the arms of the crescent being slightly prolonged obliquely
upwards. In all cases the lophophore forms the roof of the
perigastic space; in the species with crescentic lophophores
the interior of the arms is clothed with vibratile cilia.

The tentacles are tubular, closed at their free extremity
and opening at the other end into the perigastic space. In all
the Polyzoa they are armed upon their opposed sides (in Pe
cellina on one only!) with vibratile cilia, arranged in a single series, and vibrating towards the exterior, projecting from one side and
towards the base on the other. A nervous filament and muscu
lar fibres may be traced into the tentacles. In the proper
P. hippocrepia the entire plume of tentacles is surrounded at
its base by an exceedingly delicate transparent membrane in the
form of a cup or calyx, considered by Professor Allman as
analogous to the membrane of the respiratory sac in the
Tunicata; but this calyx has not yet been detected in any
marine Polyzoa. In the genus Pedeticellina the tentacles are
also surrounded at their base by a kind of membranous calyx,
which is a sort of an investment, attached to the submerged part
of the membrane connecting the bases of the tentacles of the
P. hippocrepia.

The perigastic space and the interior of the lophophore and
tentacular calyx, are filled with thousands of small, oval,
and are filled with a clear fluid, in which float numerous particles
of a very irregular form and size. This fluid obviously
represents the blood or common nutrient and respiratory fluid of other Moluscs. It is kept in motion by the cilia with
which the entire bottom is covered, but there is no special
circulatory organ as in the Ascidia.

D. Organs of Motion.

The muscular system of the Polyzoa is highly developed,
and the muscles are especially interesting in a physiological
point of view, for they seem to present an example of true
muscular tissue reduced to its simplest and essential form.
They are composed of bundles of elementary fibres, totally
separate from each other, throughout the entire body, and
which are distinctly marked with transverse strie. They
resemble in fact very closely the fibres of the thoracic mus
cles of insects. In the marine Polyzoa however another
kind of fibres may be noticed, presenting nodular enlarge
ments, which would seem to resemble very closely the isolated,
organic muscular fibres of the higher animals. These
muscles are disposed in distinct sets, and it is by the agency
of these various groups that the different movements of pro
trusion and retraction of the anterior and posterior ends, as
well as the actions of the tentacles and of the avicularia and
vibracula. For the arrangement of the muscles in the former
class of organs see fig. 8 in, the article Mollusca, S. 2.
The curious analogies in the disposition of these muscles in the
Polyzoa, between that of the invertebrate class of the Animal
Kingdom, and those of the Brachiopoda are also pointed out in that place.

E. Organs of Sensation.

A distinct nervous system was first shown to exist in the
Polyzoa by M. Dumortier in Lophophora crystallina, and has
been demonstrated by Van Beneden in Laguncula, and by
Allman in all the hippocrepian genera except Pedeticellina;
it may be deemed therefore to exist generally in the class,
and is probably developed along the same lines, as in all the
species of the hippocrepian order there may be seen,
attracted to the external surface of the oesophagus, on its
rectal aspect, just below the mouth, a hollow oval body of a
yellowish colour, which is undoubtedly a nervous ganglion,
as Professor Allman has succeeded in distinctly observing ner
vous filaments in connection with it; some of which may be
traced going to each tentacle. The ganglion also sends off
filaments upwards towards the mouth, and one may be
found near the base of the ciliary filament of the oesophagus that
nothing like a complete collar surrounding the tube has been
observed. The Polyzoa do not seem to possess any special organs of sense.

F. Organs of locomotion.

In Cristatella, the ectocyst, according to Professor Allman,
is highly contractile, and presents, below, a flattened disc,
destitute of spurrers. Upon this disc, which closely resembles
the foot of a Cestodarium, the singular polygonal creeper
about upon the stems and leaves of aquatic plants. Except
in the embryonic condition no other Polyzoa would seem to
carry capacity for locomotion; or at any rate none has
been possessed, but several reasons would seem to render it
probable that a species belonging to the Solenocysta may
be capable of locomotion by means of their curiously
constructed vibracula.

G. Reproduction.

In the Polyzoa, observes Professor Allman, there are three distinct
modes of reproduction, and they are seen to be exemplified,—By buds
or gemmæ; by true ova; and by free locomotive embryos.

1. Reproduction by Gemmæ.—The gemmæ always origi
nate in the endocyst, first appearing as small tubercles
projecting into the perigastic space, but which may soon be
seen to take a decided position in an arc or circle. The bud
now presents the appearance of a vesicle projecting from
the exterior of the parent-cell, closed at its external or free
extremity, but having its cavity in communication with the
perigastic space. The polyzoid is gradually developed in
the interior of the gemma by the differentiation of its fine
granular contents, and the extremity of the bud ultimately
opens so as to admit of the excretion and retraction of the
young animal. Thus is produced a fresh cell of the polyzo
a, whose ultimate form, as has been before observed,
depends upon the point of the cell at which the bud springs.
This differs in almost every species, and upon this difference
depends the diverse physiogomy of the various species.

2. Reproduction by Ova.—All the fresh-water, and proba
bly also, all the marine Polyzoa, produce true ova, which
sometimes remain formed in a definite form; sometimes
are thrown off in a large number, and are present in the
upper and back part, a polyzoid, consisting of a single series
of cells, such as that of Acaea, or of Hippothoa (fig. 6),
will be presented; if from each cell two are given off and remain
in close apposition, a circularly expanded disc of greater or
lesser regularity is developed, which is the regular endocyst,
which is the regular way of reproduction in the Polyzoa.
In Laguncula Professor Allman says, 'that the ovary and
testes are both found in the same cell. The former is an
irregularly shaped body, adhering to the under surface of the
endocyst, towards the upper part of the cell. The testicle
is an irregularly lobed mass attached, like the ovary, to the
inner surface of the endocyst. It occupies a position near
the bottom of the cell, and is thus separated by a wide in
terior cavity from the ovary. The ovary and testes of this
organ is described and figured by Van Beneden. In
Pedeticellina Professor Allman says, "that the ovary and
testes are both found in the same cell. The former is an
irregularly shaped body, adhering to the under surface of the
endocyst, towards the upper part of the cell. The testicle
is an irregularly lobed mass attached, like the ovary, to the
inner surface of the endocyst. It occupies a position near
the bottom of the cell, and is thus separated by a wide in
terior cavity from the ovary. The ovary and testes of this
organ is described and figured by Van Beneden. In
Pedeticellina Professor Allman says, "that the ovary and
received that name, and as to the relation which those organs bear to the rest of the animal. There can be no doubt that these organs do contain an ovum or ova, and that these ova are developed ab origine, in them, and there undergo segmentation; but how these ova are fertilised, and why a difference so great as this in the position of the ovarious organ should exist in apparently closely allied genera or even species, is at present inexcusable.

Section III. Classification.

The more general relations of the Polyzoa having, as before observed, been described under the head of Molusca, the remainder of this article will be devoted to the mode in which they may be conveniently arranged among themselves.

With our present defective knowledge of many particulars respecting the conformation of the Polypide, the classification of the Polyzoa can only be attempted with any prospect of useful results, from the study of the Polycysto; that is to say, so far as regards the determination of the subordinate groups—the orders themselves being defined by characters derived from the Polyptide, or soft portion of the animal. The following scheme, which in its main features has been long received, appears to offer as convenient, and so far as our present acquaintance with the subject allows, perhaps as natural a classification as can be expected.

Class POLYZOA.

Social molluscan animals, whose nervous system consists of a single post-oesophageal ganglion, with branches, but without a nervous ring around the oesophagus; and without any special organs of sense or of circulation. Mouth surrounded more or less completely by a single row of ciliated tentacles.

Bryozoa, Ehrenb., 'Corallen-Thiere des Roth. Meer,' 1831 (1834).
Mollusca Zoophyta, seu Zoophyta Ascidicida, John-
ston, ' Mag. Zool. and Bot.' 1836.
Ophiobrachioidea, Farre, 'Phil. Trans.,' 1837.

Order I. Polyzoa infundibulata, Gervais.

Tentacles disposed on an uninterrupted annular lophophore, surrounding the unarmed mouth.

Sub-Order I. Cheilotomata.

The crescentic subterminal mouth of the cell is furnished with a moveable lip, by which it is closed when the animal retires.

Escharacea, Planocraea, Colograda (ex. Oria), Fleming.
Polyplaxia operculifera et edellaris (ex. Oria), Blain-
ville.
Escharina, Collapsina, Ehrenberg.
Urococata (pars), Hagenow.

A. Cells disposed in a single series.

Family 1. Catenicellidae, Busk.

Cells connected by short flexible tubes.

Gen. 1. Catenicella, Blainv. (Fig. 1, 2.)

Cells connected by short conical tubes, all facing the same way; polyzoary phytod, erect, dichotomously branched; cell at the bifurcation geminate.

a. Fenestrata. Cells fenestratae in front; ovicella terminal, B. Vittata. Cells with a narrow elongated band or vitta on each side in front; ovicella girleriform, not terminal.

Catenicella, Blainville; 'Brit. Mus. Cat.,' p. 3.

Catenaria, Savigny, 'Egypt,' pl. 13.

About seventeen species known; mostly Australian.

Gen. 2. Alysiidum, Busk.

Cells connected by short conical tubes. Two cells arising from each cell at a bifurcation.

Three species known.

Gen. 3. Calpida, Busk. (Fig. 3.)

Cells with an avicularium on each side; each cell with three distinct apertures, arising one from the upper part of another in a linear series, connected by short conical tubes.

Calpida, Busk; 'Voyage of Beagle,' l. 364
(fig. 3); 'Brit. Mus. Cat.,' p. 14.

One species.
arsoles; aperture large; no avicularia; ovisells inconspicuous.

Vincaulina, Defrance; Blainv.; Hagenow; 'Brit. Mus. Cat.', p. 96.
Glaucosoma, Goldfuss.
Siphonella, Hagenow.
Cellaria (pars), Reuss.
One recent species; numerous fossil.

Gen. 4. Paracorina, Busk. (Fig. 8.)
Polyselen cuneatus, flexible; margin of aperture much raised; aperture very large; ovisells cuculate, prominent; no avicularia.

One species.

Cells disposed in the same plane, forming linear branches of a dichotomously divided phylloid, erect, articulated polyselen.

Bugulida (pars), Gray.
Cellulariades (pars), Johnston.
Escharides (pars), Johnston; Gray.

Gen. 1. Cellularia, Pallas. (Fig. 5.)
Cells bi-triserial; more than four in each internode; oblong or rhomboidal, contiguous; perforated, unarmed, or very rarely with an avicularium on the upper and outer angle of the cells.

Cellularia (pars), Pallas; Fleming; Johnston (pars); 'Brit. Mus. Cat.', p. 19.

Bugula (pars), Gray; Oken.
Three species.

Gen. 2. Menipea, Lamouroux.
Cells oblong, or elongated and attenuated downwards; perforate behind, with a sessile avicularium (frequently absent) on the upper and outer angle, and one or more sessile avicularia on the front of the cell below the aperture (not always present).

Cellaria (pars), Lam.; Solander.
Crista (pars), Lam.
Triangularia, Fleming; Blainville.
Six species.

Cells rhomboidal, with a sinus on the outer and hinder aspect; each furnished with a sessile avicularium at the upper and outer angle, and with a vibraculum behind. Cells biserial and numerous in each internode.

Saccocellaria, Van Beneden; Gray; 'Brit. Mus. Cat.', p. 23.
Bicellaria (sp), Blainville.
Cellaria (sp), Pallas; Johnston.
Cellaria (sp), Solander; Lamarck.
Saccoparia (sp), Oken.
Seven species.

Gen. 4. Canda, Lamouroux.
Cells rhomboidal, situated on the outer side for the lodging of a vibraculum; no avicularium on the upper and outer angle; sometimes one in front of the cell.

Canda, Lam.; Blainville; Gray; 'Brit. Mus. Cat.', p. 96.

Cellaria (sp), Lamarck.
Cellaria, Van Beneden.
Bicellaria (sp), Blainville.
Saccocellaria, Gray.
Cellaria (sp), Johnston.
Two species.

Gen. 5. Emma, Gray.
Cells in pairs or triplets; a sessile avicularium (sometimes wanting) on the outer side below the level of the aperture.

Emma, Gray; 'Brit. Mus. Cat.', p. 27.
Two species.

Family 5. Cylindraceae, Busk.
Polyzoary dichotomously divided into ligulate bi-multiseriate branches; on the backs of which are vibracula, each of which is common to several cells.

3 X 2
(Fig. 10.)

Cells bi-multiseriolar, in the latter case quinqueserial. Back of branches covered with large vibracula, which are placed obliquely in two rows, diverging in an upward direction from the middle line, at which the vibracula of either side decisively with those of the other.

*Salvia*, Gray.

*Bacillaria* (sp.), Audouin.

*Ciliaria* (sp.), Lamarck.

*Cellaria* (sp.), Fleming; Johnston.

Four species.

Gen. 2. *Amastigia*, Busk.

Cells bi-quadriseriolar; vibracula small, resembling avicularia.

One species.

No vibracula; avicularia, when present, pedunculate.  
*Bicellaria*, Busk.; 'Voyage of Rattlesnake.'  
*Bugula*, Gray.

(Fig. 11.)

Cells turbinate, distant. Aperture directed more or less upwards. Several spines, marginal or dorsal.

Cellaria, Fleming; Pallas (sp.).

Cellaria (sp.), Oken; Lamarck.

*Bugula* (sp.), Oken.

Four species.

Cells contiguous, attenuated downwards; much expanded above, with a large plain aperture unarmed.  

*Bicellaria*, Busk.; 'Voyage of Rattlesnake.'

Gen. 3. *Bugula*, Oken.

Cells elliptical (behind), closely contiguous, bi-multiseriolar; aperture very large; margin simple, not thickened.

*Bugula*, Oken; Gray; 'Brit. Mus. Cat.,' p. 43.

*Asellaria*, Lamx.; Blainville.

*Ciliaria* (sp.), Lamx.

*Cellaria* (sp.), Pallas; Johnston (sp.).

*Cellaria* (sp.), Solander; Lamarck.

*Bugula* (sp.), Gray.

*Oriaria* (sp.), Gray.

Six species.

Cells opposite in pairs. Polysomy continuous.

(Fig. 29.)

Cells joined back to back; all the pairs facing the same way.

Gemellaria, Savigny; Van Beneden; Johnston; Gray; 'Brit. Mus. Cat.,' p. 34.

Gemellaria, Blainville.

*Loxocordia*, Lamx.

Notomia (pars), Fleming.

*Locicula*, Cuvier.

*Crista* (sp.), Lamx.; Lamarck.

*Scruparia* (sp.), Oken.

One species.

Gen. 2. *Didymia*, Busk.

Cells joined side to side; no avicularia.

Didymia, Busk; 'Voyage of Rattlesnake;' 'Brit. Mus. Cat.,' p. 35.

One species.

Gen. 3. *Dimotopias*, Busk.  
(Fig. 9.)

Cells joined back to back; aperture oblique; each alternate pair of cells looking the same way.

Dimotopias, Busk; 'Voyage of Rattlesnake.'

Two species.

A pair of tobacco-pipe shaped avicularia, visible above each pair of cells.

Epistoma (sp.), Fleming; Gray.

Dynamena (sp.), Lamx.; Blainville.

Gemellaria (sp.), Blainville.
Family 8. Flustridae, Gray.
Polyzoary flexible, expanded, foliaceous, erect; sometimes decumbent and loosely attached. Cells multiserial, quinuncial, or irregular.

*Flustra*, Linn.; *Johnston* (pars).
*Flustra*, Gray (pars); 'Brit. Mus. Cat.', p. 46.
*Escharidae* (pars), *Johnston*; *Gray*.
*Polyplacophora* & *Ricca* (pars), *Lamx*.
*Flustralea* (pars), *Lamx*.

Gen. 1. *Flustra*, Linn. Heus. Cells contiguous, on both sides of the frond.
*Flustra* (sp.), *Linn.*; *Lamark*; *Gray*; &c.
Five species.

(Fig. 13.)
Cells contiguous, on one side only of the frond.
*Carbacea* (sp.), *Linn.*; *Johnston*.
*Carbacea*, Gray; 'Brit. Mus. Cat.' p. 50.
Ten species.

Gen. 3. *Diachoria*, Busk.
(Fig. 13.)
Cells disjunct; each connected with six others by tubular processes.
*Diachoria*, Busk., 'Voyage of Rattlesnake.'
Three species.

Polyzoarium adnate, crustaceous, spreading from a centre in a more or less circular form; composed of contiguous, or connected, calcareous, decumbent cells, the wall of which is complete in front.

*Lepralia* (sp.), *Moll.*; *Pallas*.
*Bererina*, *Fleming* (non *Lamouroux nor Pern*).
*Escharina* (sp.), *Milne-Edwards*; *Gray*.
*Escharidae* (sp.), *Milne-Edwards*.
*Cellepora* (sp.), *Oken*; *Audouin* (pars); *Lamouroux* (pars).
*Flustra* (varior).
*Cellepora*, *Lamark* (pars); *Gray* (pars); *Lamouroux* (pars).
*Oribillina*, *Herencia*, *Escharella*, *Porella*, *Cellepora* (all sp.), *Gray*.

1. *Armatia*. Species provided with either avicularia or vibracula.

A. Species having avicularia.

a. Median and single.

* Superior (above the mouth).

** Inferior (below the mouth).

B. Avicularia double, or azygous and lateral on each cell, or only on some cells in the polyzoary.

1. *Inarmata*. Species without either avicularia or vibracula.

a. With oral spines.

b. Mouth unarmed.

About fifty or sixty species.

Polyzoarium composed of cells, standing more or less
vertical to its axis or plane, hausted together, or irregularly overlying each other.

**Cephalorhiza**, Johnston (pars); "Brit. Mus. Cat.", p. 68.

Gen. 1. **Cephalorhiza**, O. Fabricius. (Fig. 16.)

Polyzoarium calcareous, rigid, adnate or erect, composed of ureolite, suberect, contiguous cells, hausted together irregularly, or arranged quincuncially. An ascending rostrum on one or both sides of the mouth usually furnished with an avunculinum.

**Cephalorhiza** (ep.), O. Fabricius; Johnston; Linnneus; Müller; Berkeley; Stewart; Lamarck; Lamouroux; Fleming; Olivi.

**Spongina**, Oken.

**Typhora** (pars), Linn.

**Millepora** (pars), Pallas; Ellis and Solander (pars).

**Eschara** (pars), Pallas.

* Adnate, globose, or spreading.

** Erect.

Eight species.

Polyzoary erect, rigid, foliaceous and expanded, lobate or reticulate. Cells disposed quincuncially in the same plane, on one or both surfaces.

**Escharidae** (pars), Johnston.

**Lepraliaceae** (pars), Gray.

**Rugosarme**, Gray.

Gen. 1. **Eschara**, Ray. (Fig. 17.)

Polyzoary foliaceous and expanded, or contorted, or branched and sublinear. Cells disposed on both surfaces, back to back, immersed, coalescent, horizontal to the plane of the axis.

**Eschara**, Ray; Fleming; Johnston; Lamarck; Gray; Pallas (pars); Moll (pars); "Brit. Mus. Cat.", p. 68.

**Nullidora** (ep.), Solander.

**Cephalorhiza** (ep.), Esper.

* Polyzoary more or less expanded, foliaceous.

** Polyzoary subdivided into branching lobes.

Eleven species.

Gen. 2. **Rugosarum**, Imperato. (Fig. 28.)

Polyzoary foliaceous, calcareous, reticulated. Cells immersed, opening at one surface only.

**Millepora**, Linn. (pars); Ellis and Solander; Esper; Marevige; Cuvier.

**Rugosarum**, Imperato; Lamarck; Risso; Fleming; Stark; De Blainville; Couch; Johnston; Goldfuss (pars); Hagenow (pars); "Brit. Mus. Cat.", p. 93.

**Fenditima**, Oken; De Blainville.

Three species.

Family 12. **Selamiaceae**, Busk.

Polyzoary more or less regularly orbicular, convex on one side, plane or concave on the other (probably free). Furnished with large and powerful vibracula, with variously formed setae (probably locomotive).

**Selamiaceae**, Busk; "Brit. Mus. Cat.", p. 97.

Gen. 1. **Cupularia**, Lamouroux. (Fig. 18; vide also figs. in **Cephalorhiza**.)

Each cell throughout the polyzoary with a vibraculum at the summit.

**Cupularia**, Lamouroux (proposed); "Brit. Mus. Cat.", p. 97.

**Lumulites**, Lamouroux (pars); Defrance (pars); Deslongchamps (pars); Goldfuss (pars); De Blainville (pars); Gray; Cuvier and Bronnuiart; Lonsdale (pars); Michelin (pars).

**Fenditima** (pars), Lonsdale.

Five species (recent); numerous fossil.

Gen. 2. **Lumulites**, Lamouroux.

Cells arranged in series radiating from the centre and bifurcating as they advance; vibracula in linear series alternate with those of the cells.

Four species (recent); numerous fossil.

---

17, **Eschara foliacea**. 18, *via Lowel*. 19, **Fenditima ovata**.

Gen. 3. **Selamiaceae**, Busk.

Only a certain number of cells, dispersed at uniform dis-
837

Pol.

A. Erecta.
Polyzoa erect, free, simple or branched, linear or expanded above; branches articulatd or continuous.

Polyzoa divided into distinct internodes, connected by a horny substance.

A single cell in each internode.
Sertularia (pars), Linn.; Berkeley (pars); Esper (pars); Cellularia (pars), Pallas; Hogg.
Cellaria, Ellis and Solander (pars); Lamarck (pars).
Esperia, Lamouroux (pars); Riso (pars); Fleming (pars); Templeton.
Uncellaria (pars), Blainville.
Creisia, Milne-Edwards.
Criosa (pars), Johnston; Hassall (pars), &c.
One or two species.

Gen. 2. Crisia, Lamouroux. (Fig. 20.)
Two or more cells in each internode.
Syn. as above.
Three species recent; several fossil.

Family 2. Idmonaeidae.
Polyzoa continuous throughout, usually polymorphous.

Gen. 1. Idmona, Lamouroux. (Fig. 22.)
Openings of cells disposed in transverse or oblique alternate series on each side of the front of the branches of the polyzoa, on which is a raised line or ridge separating the rows of cells.
Idmona (ep.), Lamarck.
Hornera (ep.), Defrance.
Idmona, Lamouroux; Blainville.

Gen. 2. Pustulipora, De Blainville. (Fig. 26.)
Openings of cells disposed irregularly, on all sides of the cylindrical or compressed branches or lobes of the polyzoa.
Ceriopora (pars), Goldfuss.
Idmona (ep.), De Blainville.
Pustulipora, Blainville; Milne-Edwards; Johnston.
Pustulipora (sp.), Couche.
Five or six species recent; many fossil.

Gen. 3. Hornera, Lamouroux.
Openings of cells disposed irregularly, or in more or less regular opposite transverse series, on one side only of the branches or lobes of the polyzoa.
Millepora (ep.), Esper.
Pustulipora (ep.), Lamarck.
Hornera, Lamouroux; De Blainville; Milne-Edwards.
Several species recent; many fossil.

B. Adnates, decumbentes.
Polyzoa adnate or suberect above, decumbent and adnate below.

Family 3. Tubuliporae.
Polyzoa divided into linear or sublinear branches or lobes, sometimes more expanded and lobate upwards, always decumbent, and closely adnate.

Gen. 1. Actico, Lamouroux. (Fig. 21.)
Polyzoa composed of a single or of multiple series of cells.
Actico, Lamouroux; Milne-Edwards; Johnston (pars);
De Blainville; Fleming.
Millepora (ep.), Linn.
Ausopora (ep.), Goldfuss, &c.
Three or four species recent; several fossil.

Gen. 2. Tubulipora. (Fig. 23.)
Polyzoa arising from a contracted base, and expanding above; either simple or irregularly subdivided; decumbent and adnate below, usually free and suberect above.
Tubulipora, Milne-Edwards (pars); Johnston (pars);
Fabricius; Turton; Cuvier; Gmelin; Cuvier (pars); Fleming (pars); Lamarck (pars); Riso (pars).
Tubulipora (ep.), Linn.; Jameson; Stewart; Bone.
Millepora (ep.), Ellis and Solander.
Collepora (ep.), Esper.
Pheresia (l), Lamouroux, &c.
Five or six species recent; several fossil.

Family 4. Discoporaeae.
Polyzoa in the form of a closely adnate, circular, or irregular disc or patch.

Gen. 1. Discopora, Lamarck.
Polyzoa a circular disc, either flat, concave, or convex in the centre, with the suberect tubes opening irregularly in all parts of the surface, and usually surrounded by a thin calccreous border.
Discopora, Lamarck; Lamouroux; Fleming.
Tubulipora (pars), Johnston.
Maloealia, Audouin.
Obelia, Quoy and Gaimard.
Madrepore, Ellis and Solander; O. Fabricius.

Gen. 2. Diastopora, Lamouroux. (Fig. 24.)
Polyzoa more or less depressed, circular, discoid; the cells subalternating, horizontal, immersed; openings elliptical.
Polyzoa either discolb and adnate throughout, or fungiform and attached by a short stem; openings of tubes disposed in lines or rows radiating from the centre.

*Peloria*, Lamouroux.

*Liopora*, Michelin.

*Tabulipora*, Milne-Edwards (sp.) ; Johnston (sp.).

*Ceripora* (anet., paro).

*Defrancia*, Brunn.; Hagenow; Reuss.

Sub-Order III. *Clenostomatata*.

Cells corneous, or fleshy, tubular or depressed, free or coalescent; mouth terminal or subterminal, contractile, and when the polypode is exserted, surrounded with a fringe or row of setae, connected by a delicate membrane.

*Vestula*, Johnston.

*Polyoa cornosa*, Gray, and including—

*Halocyonella*, Johnston.

*Polyoa cornosa*, Gray.

*Alcogoniadus* and *Alcyonidula*, Johnston.

Cells tubular or ovate, separate, arising from a basal tube common to all or to several; mouth terminal.

*Vestulaeridae*, Johnston.

Gen. 1. *Serriaria*, Lamarck. (Fig. 25.)

Cells uniserial or biserial, and uniserial, placed in close sets at staked intervals; basal tube divided into internodes.
Freshwater Polygon, Allman.
Freshwater Bryoos, Hancock.
Bryozoaires Flavislites, Van Beneden.

Family 1. Crisataellidae, Allman.
Polyzoary free, locomotive.

Polyzoary saciform, hyaline, with a common flattened disc adapted for locomotion; orifices placed on the surface opposite to the disc, and arranged in several concentric marginal series; ova lenticular, with annular and marginal spines.
One species.

Family 2. Plumatellidae, Allman.
Polyzoary rooted.

A. Lophophore with two long arms.

Gen. 1. Lophophus, Dumortier.
Polyzoary saciform, hyaline, with a disc which serves for attachment, but not for locomotion; orifices scattered; ectocyst gelatinous.
Polyta Chama Apanche, Trembley.
Bell-Flower-Animal, Baker.

Gen. 2. Alecyonella, Lamark.
Polyzoary tubular; tubes united by their sides; orifices terminal; ectocyst pergametaceous.

Tubularia, Pallas.
Leucopha, Muller.

Gen. 3. Plumatella, Lamark. (Fig. 30.)
Polyzoary tubular; tubes distinct; ectocyst parchmentaceous.

Tubipora, Linnens.

Tubularia, Muller; Linnens; Vaucher; Turton.

Nastis, Lamozeaux; Deslongchamps.

Plumatella, De Blainville; Carus; Lamark; Dumontier; Johnston; Gervais; Allman; Thompson; Van Beneden; Dalzell; Schweighe; Risso; &c.

Three species.

Ten species.

Polzoary conserved, composed of a membran-corneous branched tube, with the branches distinct and terminated by the orifices; lophophore nearly circular, tentacular crown campuseulate; ova bean-shaped, destitute of annulus or spines.

Tubularia, Blumenbach; Gmelin.
Nastis, Lamozeaux.
Diffla, Maillet.
Plumatella, Fleming; Dumontier; Johnston.
Fredericella, Gervais; Van Beneden; Thompson; Allman; Johnston; Hancock.

Family 3. Pothecidae.
Lophophore orbicular, mouth destitute of valve. (Does not perhaps properly belong to P. hippocrepia.)

Gen. 1. Pothecia, Gervais.
Polyzoary membran-corneous, branched; branches composed of a series of claviform cells, placed end to end, and separated from one another by complete septa; orifices tubular, lateral, placed near the wider extremity of each cell; ova lenticular, with a narrow annulus.

Aleyonella (sp.), Ehrenberg; Nordmann.

Pothecia, Gervais; Van Beneden; Allman; Thompson; Johnston; Hancock.

POLYCHITON, a genus of Plants belonging to the natural order of Fities, the sub-order Polyzoaceae, and the tribe Aspidiceae. The indusium is circular, attached by the centre; the veins are distinct after leaving the midrib. There are three British species -

P. Lachmata, with rigid simply pinnate fronds. Found in Alpine rocks.

P. acutilam, with linear rigid bipinnate fronds; the pinnules obliquely decurrent. Common in hedge banks.

P. angulata, with the fronds lax, drooping, bipinnate, pinnules truncate below, distinctly stalked. Found in the west of England, on sheltered banks.

(Babington, Manual of British Botany; Lindley and Moore, The Ferns of Great Britain and Ireland, nature-printed.)

POMPILED, a family of Fossorial Hymenopterous Insects. They are sometimes included with the Sphegidae. They have the collar either transversely or longitudinally square, with the abdomen more or less oval, and attached to the thorax by a very short peduncle. The legs are very long. The fore wings have two or three perfect submarginal cells, and another commenced at the tip of the wings. The species are called Sand Wasps, and are amongst the most ferocious of the insect tribes. The species of the exotic genus Pepsis are amongst the largest of the Hymenoptera. The genus Pompilius is British. The species are very active, running amongst grass and other plants in hot sandy situations. They are quick in their motions, and their wings are constantly sputtered. Their long legs give them the appearance of spiders. (Westwood, Families of Insects.)

PONERA (Latrelle), a genus of Insects belonging to the family Formicidae. In this genus the females and females are armed with a sting. The peduncle of the abdomen is formed of a single knot; antennae in these individuals thickened at the tip; mandibles triangular; head sub-triangular. P. contracta is a small species, a native of England.

POOL, or WELSHPOOL. [Montgomeryshire.]

POONAHILITE. [Mineralogy, &c.]

POOR LAWS. There have been several statutes making slight alterations and amendments in the details of the administration of the Poor Law, but none calling for particular mention, any analysis or enumeration of their provisions being impossible within the compass of this article.

Under the head of Pauflreis ['Penny Cyclopaedia', vol. xvii. pp. 327-30], an account was given of the establishment of the new Poor Law in England in 1834, and of its early operation up to the year 1840. Since that time the number of Unions has been increased from 597 to 624, including 14,165 parishes in England and Wales, and leaving only 436 parishes which do not make returns to the General Poor Law Board. The new Poor Law had, on its introduction, effected a large reduction of the expenditure on the poor, but from 1839 a gradual increase took place for several years. In the former article it was shown that there was no connection between the amount of relief required by the poor and the price of corn. As the subsequent returns only confirm the same fact, we shall omit the price of wheat,
and give the total amount levied for poor-rates in each year.

The years end uniformly at Lady Day. The second column gives the total amount levied for the third year, the amount expended for the maintenance and relief of the poor.

In the years above mentioned we may observe that in 1852 the average price of wheat was 39s. 4d.; in 1840 it was 68s. 6d.; yet the amount of relief shows a small difference. The number of persons relieved is an imperfect guide to the amount of distress, as it does not distinguish, except as regards in-door relief, between a single meal or assistance for a lengthened period, but we add a few statements of numbers at different periods. In the quarter ending Lady Day 1840, 13,529 persons out of 20,055 in workhouses were 1,230,927 had out-door relief. The relief continued to increase till 1843, when the number in the house was 238,660, and receiving out-door relief 1,300,920. The numbers then slowly decreased till 1847, when the In-door relief was 7,086,355, and receiving out-door relief amounted to 1,961,652. The estimated total for the year, however, including 214,670 for places not included in the returns, was 1,043,866. In 1853 the number similarly calculated had sunk to 975,030. On Jan. 1, 1857, the total number of paupers in receipt of relief, in-door and out-door, in 624 unions and parishes of England and Wales, was 843,430, being a decrease from 1856, in the same number of unions, of 33,325, or 3.8 per cent. Of adult able-bodied paupers relieved, exclusive of vagrants, there were 50,572, or 6.2 per cent. of the able-bodied population, of which number relieved, 50,269 were widows, a decrease in the same class of 2291. Of the gross number of able-bodied paupers, 32,365 were in the receipt of in-door relief, a decrease of 1186 only, so that the chief decrease is in out-door relief. The greatest decreases took place at Bedford, Lancaster, Nottingham, Rutland, and Caernarvon, where it exceeded 20 per cent. In Kent, Hereford, Durham, Oxford, Sussex, and Worcester, there was an increase, as also in several of the Welsh counties. Of the in-door able-bodied, there were 842 married men, 1007 married women, 5921 other males, and 14,677 other females. Of the out-door able-bodied, 23 males had been relieved in cases of sudden or urgent necessity; 17,210 males in cases of their own sickness or accident, 6856 males in cases of sickness or accident in their family, or for a funeral; 3784 males for want of work or other causes; 22,830 females were wives of adult males, 50,383 were widows, 5114 were single women without children, 2090 the mothers of illegitimate children; 2018 were wives relieved on account of the husband being in jail, &c.; 1268 were wives of soldiers, sailors, and marines; and 4389 were wives of other non-resident males.

The amount expended in the half year ending Lady Day 1857 for the relief of the poor was 1,979,882, of which 493,076 was for in-door maintenance, and the remainder for out-door relief.

Ireland. In consequence of the distress occasioned by the good and bad harvests in previous years, it was considered necessary to provide a poor-law for Ireland. Accordingly, in 1838, an Act (1 & 2 Vict., cap. 50), mainly founded on the reports and recommendations of Mr. (now Sir) George Cornewall Lewis, was passed. The Act resembled the English poor-law, but the workhouse as a test of need was more stringently enforced. Mr. Nicholls was appointed chief commissioner, and under his direction it came into operation in 1839. The unions were formed in 1840, and the first returns of the third year showed that the expense amounted to 5,359,022. The amount was so great, that loans to a large amount were granted for that purpose by government, a considerable portion of which was subsequently remitted. In 1840 there were but four unions in operation, North and South Dublin, Cork and Limerick. On Jan. 1, 1841, there were 25,900 in workhouses, of whom 10,910 had been relieved in the year, and the expenditure had been 37,057l. On Dec. 31, 1841, there were 37 unions in operation, and there had been relieved 31,105 destitute persons, and 15,246 were then in receipt of relief. The total expenditure had been 177,771l. On Dec. 31, 1842, there were 31,073 inmates in 92 union workhouses, 87,604 persons had been relieved, and the expense had been 281,233l. On Dec. 31, 1843, there were 33,510 inmates in 106 workhouses, 298,595 persons had been relieved, and the expenditure had been 343,274l. On Dec. 31, 1844, there were 39,175 inmates in 115 workhouses, 105,395 persons had been relieved, and the expense had been 399,530l. In 1845 another period of distress occurred through the failure of the potato, and the number of the destitute continued to increase. On Dec. 31, 1845, there were 42,068 inmates in 123 workhouses (in March 1845 there had been 50,717), 114,205 persons had been relieved, and the expenditure amounted to 516,024l. In 1846 the potato-rot continued, and the government was forced to intervene for its relief by providing public works to employ the able-bodied, by reducing the duty on the import of corn, and by furnishing food at a low price to the destitute poor, in which office Mr. Canning took a prominent part. The total relief amounted to 98,004l., the whole sum contributed amounting to 631,372l. The greatest number of persons employed at one time on public works was 97,000. On Dec. 31, 1846, in 130 workhouses there were 94,437 inmates, 245,929 persons had been relieved, and the expenditure had amounted to 430,625l. But the evils arising from the continued failure of the potato continued to operate. Food was scarce, and the public works, instead of alleviating the distress, seemed likely to increase it, and the government was compelled to suspend them. The fisheries were deserted, and even artisans left their trades. In October 1846 there were 114,000 men employed; in January 1847 the number had increased to 670,000; and in March to 734,000. It was evident a change of system must be adopted. Experiments were made to apply again the workhouse test, and the number rapidly fell, in April to 620,000, in May to 419,000, in June to 101,000, on the 26th of which month it was reduced to 29,000, and in August only 10,000. In 1847 a new government was in power, and 18,000,000l. had been supplied, and in July 1847, 3,020,712 persons received separate rations. The entire amount advanced by government in 1846 and 1847 had been 7,132,395l., and the amount subscribed had been upwards of half a million. It was in 1848 that the change of system was successfully completed.
had gradually been instituted, and in Sept. 1833 the total number of boys in the workhouses of Ireland, between the ages of 9 and 15, was 12,520; of girls, between the same ages, 14,573; of these, 8,973 boys were employed in agricultural labour, and so many girls; the number of acres, of which 1,070 were under crop, wholly or partially cultivated by boys; and 3,196 were receiving instruction in trade. Of the girls, 9,166 were receiving industrial education of various sorts. Of these, 2,032, or 21.5 per cent, had been in the workhouse for fifteen, or had obtained employment, during the year 1832, out of the workhouse. On Sept. 29, 1834, the total number of persons receiving in-door relief during the year had been 315,380, out-door 7954, the total expenditure being 74,607L. On the 1st of November 1834, there were 12,888 rates-payers receiving relief; during the year the total expenditure had been 269,900, out of the house 33,342L, total expenditure 683,596L. On the first Saturday of January, 1837, in the 163 unions of Ireland, there were 58,183 persons receiving in-door relief, and 511 out-door relief, showing a total decrease of 16,900 persons—23.3 per cent.—from the Return of the same date in 1836. Less than a third of the workhouse accommodation was in use, provision having been made for 199,667, which is itself a reduction of the provision for previous years. The poor-rate collected in the year ending September 29, 1836, amounted to 723,797L, of which 76,160L. were expended for Poor Law purposes, being a decrease on the preceding year of 109,098L. For medical charities 88,990L. were paid, and 434L. on account of annuities. In the year 1836 the amount of out-relief paid throughout Ireland was 44L.; in the year ending Sept. 29, 1836, it was 2198L., while emigration expenses amounted to 417L. It has been shown that there has been no effective legal provision for the poor. As early as 1570 power was given to magis-
trates in burgesses and justices in the country, a power afterwards transferred to the heritors and kirk sessions of parishes, to assess the parish for the support of the poor; but no assess-
ment was made under this authority after its passing, and when it became necessary in some few parishes it was confined to them alone. Other acts were passed for pre-
venting begging, for providing houses of correction for vagrants, for compelling each parish to maintain and provide for the able-bodied. But, as a general practice, the wants of the infirm, sick, and impotent poor were relieved by the voluntary contributions received at the kirk, and distributed by the kirk sessions, usually in the form of assistance to the relatives or connections of the de-
situte persons who undertook their support. This system did not work badly in country districts, except in periods of extreme and general distress. But when, by the extension of manufactures and commerce, the population increased in large towns, and the influx of strangers took place to them, the necessity of a more perfect system was very shortly felt. This had been experienced in Glasgow, Paisley, and Dundee on various occasions, but temporary expedients and increased voluntary efforts had been used to maintain a tolerable state, until 1841, and 1842, however, the distress in Paisley could not be thus relieved, although it had been in less severe trials in 1819, 1827, and 1837. At the census of 1841 the population of Paisley amounted to 46,418; in January, 1842, the number of persons d-pending on the relief fund was 12,709, and in the following June it was still 10,417. The inhabi-
tants at a public meeting, agreed to a voluntary assessment of 15 per cent. on their parochial rates, and this produced 874L. 7s. 6d. which was placed in the rates-payers' suffering. Relief aid was sought, and subscriptions to the amount of 25,000L. were obtained, a trifling alleviation of a suffering that the relief committee described as frightful. The law and the practice had always been in Scotland to refuse relief to able-
bodied adults, consequently the unfortunate artisans, deprived of his employment by the commercial difficulties occurring between 1838 and 1843, was not considered as belonging to the class receiving relief from the kirk sessions. The number of kirk sessions which in 1834 had no rates-payers amounted to 700, and the expenditure on them had been 3698L., neither the number nor the amount varying much from the usual average.

In 1849 a government commission was appointed to in-
quire into the condition of the poor in Scotland and the mode of managing the poor in Scotland. They reported that the parishes in most large towns had been forced to resort to assessment, but that it was generally disliked, and that the modes of assess-
ment were so various in different places that it was difficult to make one that should be strictly just. Here and there they found a poor-house of very inadequate accommodation, and the system was almost uniformly one of out-door relief. The report recommended a legislative enactment for a regular system of poor-laws, and accordingly in 1845 the 8 & 9 Vict. c. 55 was passed. It created several boards of manage-
ment elected by the rate-payers, a board of supervision; gave the power of levying assessments; the option of com-
bining parishes for the erection of poor-houses; made a more flexible legislation regarding the state of the parish, the condition, and unsettled poor, for medical relief, and for retirement and assessment; but it still leaves the able-bodied adult without a legal claim on parochial assistance. Each parish is allowed to decide whether the requisite sum for the relief of the poor shall be raised by contribution or assessment, and if by assessment, how certain properties shall be classed; but having once decided in favour of assessment, they cannot retract such decision without the consent of the board of supervision. The voluntary system had been the custom, and out of 380 parishes in Scotland, only 289 had actually assessed in 1842-43; these have been gradually increased, so that now (1838) there are but few in which a legal assessment has not taken place. Although the Act was brought into immediate operation, it was some time before the registers and accounts could be reduced into proper forms. Officers and inspectors were alike inexperienced. But according to the best returns the commissioners could obtain from the several parishes, the expenditure for the year ending Febru-
ary 1, 1846, was 1,475,418L. From this it appeared that from all sources there was raised for the relief of the poor in 1836 the sum of 171,042L. and 218,461L. in 1841; the amount having gradually increased in every succeeding year, and the circumstances that in 1841 were not stated, but on February 1, 1846, there were 63,070 on the poor roll. In the year ending February 1, 1846, there had been raised 306,044L., of which 295,239L. were expended in poor relief. In the autumn of 1846 the potato rot visited Scotland, and again in 1847, it continued to spread over a vast amount of dis-
tract, particularly in the Western Highlands and Islands of Scotland. Government aid was offered, and poor-houses and medical relief were strongly recommended, and in most instances adopted, particularly the relief of medical care. For the few following years there is no progress in the case as stated.

During these years the highest number of the poor on the register was 82,337 in 1849, the lowest 69,433 in 1846; the greatest number of casual poor relieved was 126,054 in 1848, the lowest 56,033 in 1832. The number of houses were frequently large more than 3500; and the number of orphans or deserted children have increased from 4794 in 1847 to 5328 in 1853. The figures for the following years vary little in their details, showing chiefly an increase as the system extends, and as the returns are published. In the year ending May 14, 1857, the total amount expended in poor-law relief was 639,484L., including 27,577L. on buildings, on medical relief 61,553L., on law charges 27,277L., and on management 7290L. The number of registered poor who received relief in the year ending May 14, 1857, was 88,092, a decrease of 10,740 from the previous year; and the casual poor receiving relief amounted to 36,545. The number of poor-houses in 1856 numbered 30, belonging to 150 parishes, in which there were 15,043 inmates, and 16 others were in course of erection. The number of registered poor on the 14th of May, 1857, was 60,217. (History of the Poor Laws. By Sir George Nicholls.)

PORT MELBOURNE. [SOUTH AUSTRALIA, &c.]
PORT PHILLIP. [VICTORIA, &c.]

PORTER, ANNA MARIA, born at Durham about 1751, was the youngest child of a family all of whom attained considerable eminence. Her eldest brother, Robert, was an English Architect at Bristol; another brother was Sir R. K. Porter; and her eldest sister was Jane, the subject of the following notice. When only a few months old her father died, and the mother, for the sake of educating her children economically, resolved to send Edith, the eldest daughter, to school. She was a precocious; and as a lively and intelligent child attracted the notice of Sir Walter Scott, then a youth, who delighted in relating tales to her, and this probably led to her early attempts in the same line. While still almost a child she became intimate with the Watts family. She was married twice; first to a merchant in London, who died in 1793 and 1795, of which she afterwards regretted the publication. Her mother had before this time removed with her family to London, and subsequently, with her sister Janet, they settled first at Thames Ditton, and finally at Esher. After the death of her mother in 1831, while travelling in hopes of restoring her delicate health, she was attacked by typhus fever, and died on June 21, 1832, at the seat of Mrs. Colonel Booth, Montpelier, near Bristol. Before her death, it is said, she had published numerous novels, among which 'The Hungarian Brothers,' 'Don Sebastian,' 'The Recluse of Norway,' 'The Village of Mariendorf,' 'The Fast of St. Magdalen,' and 'The Knight of St. Johns,' enjoyed and retained considerable popularity. Her works were, on the whole, neither original nor fresh, nor do they contain any of the highest qualities of the art. She was a good story-teller, and skilful in the management of the story, and some discrimination of character; but her heroes and heroines too often possess a superhuman excellence that becomes palatable. 'The Tales of Pity,' were published anonymously, and are intended to inculcate kindness to animals. In 'The Barony' she has developed her religious feelings. She also published a volume of poetry, 'Ballad Romances and Other Poems,' in 1811, of no great value.

PORTER, Sir Richard, one of the elder set of brothers, was born in 1776. Her life followed that of her sister, with whom and her mother she constantly resided till their deaths. She then, as she described herself, 'became a wanderer,' living with one or other of her friends till, in 1842, she went with her brother to St. Petersburg. On his death she returned to England, and resided with her eldest brother, the physician at Bristol, where she died May 24, 1860. Miss Jane Porter did not adventure into the field of literature till after the death of her brother, and in some respects the works were better prepared, but she has the same fault in the unmitigated excellence or depravity of her characters. Still, in many of her characters there is a finer delineation, and perhaps somewhat greater knowledge, though not very rigidly adhered to in捃 the lower classes. 'The Thai trencher.' Her first work was 'Thadeiess of Warsaw,' published in 1803, which was extremely popular, and procured for her the admission as a canoness into the Teutonic order of St. Josehin, and a complimentary letter from Koecisouko. In 1809 she published the 'Scottish Chiefs,' a romance of Wallace and Bruce, in which there is considerable vigour of description, some character, but a total misconception of the condition of the time. Wallace and Bruce are depicted as little less than demi-gods. To these followed the 'Pastor's Fireside' and 'Duke Christian of Luneburgh,' the latter said to have been suggested by George the Fourth. She next joined with her sister in 'Tales round a Winter's Hearth,' and those were followed by 'The Field of Forty Footsteps,' founded on a London tradition connected with the spot where now stands University College and Hospital, and which was almost immediately dramatised. After a considerable interval, during which she contributed largely to periodical works, among others being a biography of Colonel Denman, the African traveller, in the 'Naval and Military Journal,' she published anonymously in 1831 'Sir Edward Seaward's Diary,' in which she so successfully imitated the style and characters of the better writers and history of the period, that it was for a considerable time doubted whether or not it was a fiction. This was her last work.

PORTER, GEORGE RICHARDSON, was born in London in 1792. He was educated at Merchant Taylor's school, where he was intimately acquainted with the Ricardo family, and subsequently married the sister of David Ricardo. His father, a merchant in London, designed him for his own profession, and he became a sugar-broker. He was unsuccessful in trade, but of commercial knowledge, and of some use for literary objects. In 1830 he published a work, 'On the Cultivation of the Sugar-Cane.' A paper on 'Life Assurance' was published in the 'Companion to the Almanac for 1831.' In the same year 'A Treatise on the Origin, Progress, and Projection of the Bank of England System of Paper Money and Bank Credit,' was issued in a volume of Lardner's 'Cabinet Cyclopaedia,' for which series, in 1842, he wrote a similar treatise 'On the Manufacture of Porcelain and Glass.' His paper in the 'Companion to the Almanac,' of which Mr. Charles Knight was the editor, were afterwards published in his official appointment in the Board of Trade. In an article in the 'Gentleman's Magazine,' for October 1825, the circumstance is thus correctly stated:—"Mr. Knight was written to by the late Lord Auckland, and was requested that he would wait on that minister at his office at his earliest convenience, and was asked at the interview whether he would undertake the task of arranging and digesting for the board the mass of information contained in blue books and parliamentary returns; in short, if he would do for the Board of Trade what Mr. Porter has since done so well, and what Mr. Fonblanque continues to do for the same office, with the same accuracy and success. Mr. Knight hesitated. The engagement, however, was accepted, and Mr. Porter made a tolerable measure with his business as a publisher. In this dilemma, he consulted a distinguished friend, and by that friend was advised to wait on Lord Auckland, and decline the office. This he did; and at Lord Auckland's request, he named Mr. Fosh, who had been appointed to that position." The first appointment of Mr. Porter at the Board of Trade took place in 1832. It was an experimental appointment at a small salary. When the statistical department of the Board of Trade was fully organised, Mr. Porter was placed at its head. In 1840 he was appointed in addition, senior member of the railway department of the board, then newly constituted to meet the growing increase of projects in that direction. His able reports, which were laid before Parliament in the last quarter of the same year, were appreciated by official men and by the public. For his labours in this department he had an additional salary of 200l. a-year. On the retirement of Mr. McGregor, as one of the secretaries of the Board of Trade, in 1841, Mr. Porter was appointed to succeed him, at the salary of 1500l. a-year. His labours in all these positions were increasing and successful. He had a genius for tabulating the most incongruous materials, and he formed the model, which he afterwards carried out, of a system of accounts, as the data was collected, and which has actually been issued from the Board of Trade with so much advantage to the commerce of the country. But his active mind was not confined to his official duties. In 1833 he published 'The Tropical Agriculturist.' In 1834 he exerted himself for the cause of the convicts in Australia, and then for a considerable time one of the vice-presidents, and on the resignation of Mr. Hallam in 1841, he was chosen treasurer. To the 'Journal' of the Society he was a frequent contributor. In 1836 he published 'The Progress of the Nation, in its social and commercial relations, from the beginning of the Nineteenth Century to the Present Time. Sections I. and II., Population and Production." Sections III. and IV., "Interchange, and Revenue and Expenditure," followed in 1838; and the work was completed in 3 vols. 12mo, by Sections V. to VIII., including 'Consumption, Accumulation, Moral Progress, Colonial and Foreign Dependants.' This valuable work necessarily admits of constant corrections. "The New Tables of "The New Tables of Trade, and other observances of the country," issued in a large 8vo volume, in 1847 and 1851. The most important information clearly set forth in this work presents the best and most complete picture of the progress and state of the country for the period of which it treats. On the establishment of the British Association for the Advancement of Science, he became one of its most active members, always attended its annual meetings, and usually read a paper to the statistical section. Mr. Porter had been ever a firm and unswerving advocate of the doctrines of free-trade, and in 1849 he published a pamphlet entitled "Free Trade for All," and "Popular Fallacies regarding General Interests," in 16mo. In the same year he wrote the Fifteenth Section of the 'Admiralty Manual of Scientific Inquiry,' edited by Sir J. F. Herschel, which was subsequently published alone in 1851. In 1850, in conjunction with Mr. George Long, he

Digitized by Google
wrote the 'Geography of Great Britain. Part I. England and Wales,' published at York for the Diffusion of Useful Knowledge. This was his last unofficial labour. Sedentary pursuits had induced a bad habit of body, and the sting of a gnaw produced inflammation of the leg, from the consequences of which he died on September 3, 1855, at Tombridge Wells, whether he had gone in hopes of relief.

In addition to the above political divisions, each of the sub-provinces or districts is subdivided into comarcas (or judicial divisions), cancellos (or communal divisions), and parishes. The total number of comarcas is 111; of cancellos, 379; and of parishes, 3774.

PORTUMNA. Galway, Ireland, a market-town and the seat of a Poor-Law Union, is situated at the head of Lough Derg, in 53° 6' N. lat., 8° 12' W. long., 41 miles S.E. from Galway, and 94 miles W.S.W. from Dublin. The population in 1861 was 1,542, besides 147 in the Union workhouse. Portumna Poor-Law Union comprises 16 electoral divisions, with an area of 77,046 acres, and a population in 1861 of 30,714; in 1851 of 19,731. The town has been much improved by the increased trade of the Shannon. It contains the parish church, a handsome structure in the perpendicular style; a large Roman Catholic chapel; a dispensary; Union workhouse; and bridewell. The Shannon is here crossed by a causeway and wooden bridge 600 feet in length. Quarter and petty sessions are held in the town. Saturday is the market-day; fairs are held six times a year. Portumna Castle, a fine baronial mansion, the seat of the Marquis of Cianricarde, was destroyed by fire in 1856.

POST OFFICE. In the 'Penny Cyclopedia,' vol. xviii. p. 453, there was given under this head an account of the Post Office up to and inclusive of the improvements introduced by Mr. Rowland Hill. All that remains is to notice what has been done in the way of extension of the advantages derived from rapid and cheap intercommunication, and a few figures to show the enormous increase which has taken place. In 1858, as stated in the previous article, the total number of documents transmitted by post, including franks, public statutes, and newspapers (of which there were 44,500,000), was 136,423,836. In 1839 the new system was introduced, but 1840 was the first entire year of the penny postage, but then letters might be paid, or stamped, or were charged double. In that year 82,000,000 letters were passed through the post-offices of the United Kingdom. The revenue derived from the post-office had been 1,649,088l. in 1839; in 1840 it only amounted to 495,614l. In 1845 the number of letters had reached 250,161,611, and the revenue 708,670,089l.; the number of letters and the amount of net revenue continued to increase rapidly. In 1848 the additional advantage was given of a book-post, by which single books could be sent, open at the ends, at an uniform rate of 6d. per pound. This privilege was gradually extended to the British Colonies. In 1855 the rate of post-office printed sheets was reduced to one penny for a quarter of a pound, twopenny for half a pound, and twopence extra for each fraction above half a pound; but if fourpence or upwards were written on the packet more than 3d. for 4 oz., 6d. for 8 oz., and then proceeding at the rate of 6d. for every 8 oz., or portion thereof, except to Ascension Island, the East Indies, Hong Kong, Australia, New Zealand, and the Gambia Colony, all of which they are all charged 6d. per pound more, and the weight is restricted to three pounds. By various conventions the foreign postage of letters has been materially reduced, in some cases 50 per cent., and in others varying from 17 to 20 per cent. The rates to all the British Colonies were in 1857 reduced to an uniform rate of 6d. per half ounce, payable in advance.

The fourth annual return of the Post-Office for 1857 states that the total number of letters delivered in the year was 504,491,000, of which 303,600,000 were in England and Wales, 42,306,000 in Ireland, and 51,618,000 in Scotland. These numbers give an average, in England, of 21 letters for each person of the population (in London it amounts to 43 for each), in Ireland to 7 for each, and in Scotland to 16 for each person. The number of newspapers passing through the Post-Office was 71,000,000, about three-fourths of which bore the newspaper stamp. The number of book-packets was about 6,000,000. There were 880,000 newspapers, and 1,700,000 letters that from various causes could not be delivered, chiefly from illegible direction, or erroneous address. The gross revenue was 2,928,858l.; the cost of management 1,720,814l.; the net revenue 1,208,374l.

The cost of management includes the following items:—Salaries, pensions, &c., 1,119,485l. Postage-stamps, 110,301l. Post-office uses of railways, 490,000l.; by coaches, carts, &c., & wages of mail-guards, 165,000l.; by mail-packets (when paid for by the Post-Office) and private ships, 12,000l.; for manufacture of postage-stamps, 26,000l.; miscellaneous, including conveyance of mails in the Colonies, under the postal direction of the postmaster-general, the conveyance of the mails through Egypt, clothing for letter-carriers and guards, rents, taxes, law expenses, &c., 109,672l.

The business of the Money-Order Office has also greatly increased; and, while it affords great advantages to the public in the transmission of small sums, has become a source of profit to the establishment. In 1857 the total number of money-orders issued in the United Kingdom was 6,386,702, or 124,862 for every 100 persons of the population; over 1856. Of the total number 5,417,303 orders, to the amount of 10,410,863l., were issued in England; 459,632, to the amount of 818,337l., in Ireland; and 512,574, to the amount of 590,572l., in Scotland. The commission gave a profit, after interest, in England, of 38,012l., and in Scotland of 1180l.; in Ireland there was a loss of 618l. The number of orders gives an average of 1 for every 4 persons in England, for every 6 in Scotland, and for every 14 in Ireland. Money-order offices have also been established at Malta and Gibraltar.

In 1855 some important improvements in matters of detail were introduced with great success. Country letters to London, or passing through London, were either sorted at the provincial post-office, if necessary, or sent by the宫廷 post-office and expedited the morning delivery in London by nearly an hour. Pillar letter-boxes were also erected in London, Edinburgh,
Dublin; they have been since extended to most considerable places in the United Kingdom, and of these there are now 703. London was also divided into 10 districts, each having a district head-office, by which letters posted in a district for a different post-office were returned. The mails then were conveyed in transmission to the chief office, and thus a more speedy delivery is attained; and this division also greatly facilitates the sorting of inland letters; but to effect this the initial letters of East Central, West Central, North, East, South, West, North-East, South-East, South West, and South must be distinctly placed at the end of the direction after 'London.' A book, price one penny, has been published, distinguishing all the streets and places within the different divisions.

Nearly every town of any size throughout the three kingdoms has at least two deliveries a day from and to its metropolis and the larger provincial towns. In 1856 there were 62 such towns added to the list; for instance, in 1858 Manchester has four communications daily with London, Birmingham, Oldham, Bradford, Ashton-under-Lyne, Halifax, Sheffield, Wakefield, and Chesterham; seven with Liverpool; and five with Leeds, Stockport, Rochdale, and Bolton; twenty-nine mails are despatched from, and the same number received at, the Manchester post-office every day. In 1856 the mails within the United Kingdom were conveyed daily over 192,480 miles of way; of this, 30,172 miles are by railway at an average rate of 5d. a mile; 20,997 by coaches, mail-cars, &c., at an average rate of 6d. a mile; 63,438 by carriers foot, at an average rate of 1d. a mile; and 28,796 by packets and boats between different places in the United Kingdom, at rates varying from 5a. 6d. a mile to 4d. a mile.

The total number of persons engaged in the service of the Post-office in the United Kingdom was 22,731 on December 31, 1857, including 1 postmaster-general; 5 secretaries, assistant secretaries, and secretaries for Ireland and Scotland; 15 surveyors; 19 other superior officers, such as heads of departments, chief clerks in the Metropolitan offices, &c.; 11,101 postmasters; 1610 clerks (exclusive of some employed temporarily); 204 guards; 10,427 letter-carriers, messengers, &c.; 8 marine officers; 126 postmasters, clerks, &c., in the Colonies; and 51 agents in foreign countries. Of these, 15,163 are employed at the post-office (and including this number) about 3200 are employed in the London district.

The third annual report of the postmaster-general for 1856, in an Appendix, states that "in no part of the United Kingdom has more been done for the welfare of the people by the use of railways for carrying mails and by the penny postage system than in Ireland." In 1874 there were posts six days a week on only four lines of road; letters to all other parts of the kingdom were only transported on a single day. Now there are daily posts to almost every village, and but one important town that has not two daily mails both with London and Dublin. In 1784 the whole expense of the official mail service was 105,084l., including salaries of mail-postmasters and the conveyance of mails. Out of this, 56,600l. only was allotted to the provinces; the sum now (1856) allotted for the like service is 134,000l., divided thus: conveyance of mails by railways, 65,000l.; by coaches and cars, 27,166l.; by foot-messengers, 10,334l.; and salaries and wages paid in provincial offices, 31,122l. In 1859 the cost of conveying the mail by mail-coaches was nearly four times the average rate of England; this excess has now disappeared, and in 1859 the average was 4d. a mile for England 2d., for Scotland 3d., and for Ireland 2d.

The same paper pays the following just tribute to the exertions of Mr. Bianconi for the improvement of intercommunication in Ireland, particularly in reference to the transmission of letters:

"In 1815, Mr. Bianconi first carried his Majesty's mails in Ireland; but he did so for many years without any contract. He commenced in the county Tipperary, between Clonmel and Killamoil, and made his own bargain with the postmaster, as he did for the rest of the kingdom. He then sent the postmaster usually retained one moiety of the sum allowed, as his own purquisite, and Mr. Bianconi performed the work for the remainder. What Mr. Bianconi received was thus very small; but, in 1830, he found that the improvements he had made, and which were not incurred to his passenger traffic, or faster than was convenient to him. From 1830, when the English and Irish offices were amalgamated under the Duke of Richmond, the public, as Mr. Bianconi says, got something like fair play; and he and others were allowed to carry the mails by direct contract with the Post-Office. From that time till 1848 Mr. Bianconi continued to increase his establishment; and in the latter year he had 1,400 horses, and daily conveyed 3,800 miles. The opening of the canals and railways rendered the services of horse traffic, as to expel his cars from all the main lines. But Mr. Bianconi has met the changes of the times in a resolute spirit. He has always been ready at a moment's notice to move his horses, cars, and men to any district, however remote, where they might be required. At a moment's notice 1,000 horses, working in the metropolis of London, were moved to the town of Wexford in the south-east, to the mountains of Donegal in the north-west. Mr. Bianconi has done the State good service. By birth he is, as is well known, an Italian, but he is now naturalized, and England, as well as Ireland, should be ready to acknowledge his merits; it must be said that no living man has worked more than he has for the benefit of the sister kingdom."

The amount of postage collected at different towns in the United Kingdom (including the postage stamps sold by the Post-Office and by the Board of Inland Revenue) shows some curious results. London, of course, through which passes nearly one-half of the total correspondence of the kingdom, attains a great predominance, the amount in 1857 being 509,283l.; the next was Edinburgh, with 104,665l.; while Manchester, with 316,100 inhabitants, only contributes 89,762l.; and Birmingham, with 232,000 inhabitants, but 42,107l. Bristol, with about 100,000 inhabitants (including Bedminster), furnished 26,004l. Leeds with 272,279 inhabitants, only 18,550l.; and Sheffield, with 135,000 inhabitants, no more than 16,365l. In Ireland the contributions are more in accordance with the size of the towns:—Dublin contributes 60,391l.; Belfast, 15,547l.; Cork, 11,915l.; and Limerick, 8,977l. In the small town of Edin-burgh, with 160,000 inhabitants, contributes 59,177l.; and Glasgow, with 358,000 inhabitants, only 68,877l. It must be recollected, however, that in many cases some towns are used as a sort of depot, from whence postage-stamps are distributed to different points in the kingdom.

**POTATO. SWEET. [Battan.]**

**PUTTINGE, RIGHT HON. SIR HENRY, Bart. G.C.B., was born in 1789, of an English family which had been long settled in Ireland. He was the fifth son of the Edward Curwen Pottinge, Esq., of Mount Pottinge, county Down, by Anne, daughter of Robert Gordon, Esq., of Florida Manor, in the same county. He went to India as a cadet in 1804. At an early age he attracted the attention of the civil and military capacity, as well as his ready store of information bearing on his profession. Rising by gradual steps, he became successive judge and collector at Ahmednagar in the Deccan, and (the office of the additional collector-general) in the former capacity of the office of the finance of the revenue of the province of Scinde. For his services in these capacities he was raised to a baronetcy, when General Keane was rewarded with a peerage after the Afghan campaign in 1839. He had scarcely returned to England when war broke out between England and China on account of differences relating to the opium trade. In this emergency he was sent out to China as ambassador extraordinary and minister plenipotentiary, and superintendant of the British trade in that country; and in this two-fold capacity he took very decisive measures. Having returned to England in 1844, he was appointed high commissioner in the government of New South Wales, and was a member of the council of the colony. Having officiated, he proceeded to concert his measures with Admiral Sir W. Parker, the result of which was the capture of Amoy. The effect of this step was to throw open to English vessels a commerce with upwards of 300,000,000 natives, and the terms of the treaty were thought to be such as to afford a guarantee against the necessity of the repetition of offensive measures. For these services Sir Henry Pottinge was made a Knight Grand Cross of the Order of the Bath, and governor and lord of the British resident of the island of Peeping Kong. Having returned to England in 1844, he was sworn a member of the Privy Council, and a pension of 1500l. a year was settled on him by a vote of the House of Commons. In 1840 he was born at Bath, and was raised to the dignity of a baronet in 1839. In 1846 he was placed in the post of governor of the Madras Settlements, the chief seat of the British East India Company, and was placed under the command of Lord Maitland in the governorship of the island of the Good Hope; this office he held until the September of the following year, when he returned to India as governor and commander-in-chief of the presidency of Madras. He returned to England in 1846, having previously been raised to the local rank of lieutenant-
general in India. He died at Malta, on the 18th of March 1856, leaving behind him the reputation of an able and upright administrator, and an officer who had rendered great services to his country.

POTTON. [Bedfordshire.]

PRADEII, JAMES, was born at Geneva in May 1792. While quite young he went to Paris, and placed in the studio of the sculptor Lenoir. His first public success was gained in 1815, when, through a technical informality, his model being pronounced unqualified to compete for the first prize of the Academy, an extra gold medal was awarded him. Chiefly from the public encouragement he obtained for his group of Philoctetes the first prize, and with it the privilege of proceeding as Academy student to Rome. In that city he remained five years, and produced during that time several original works. Although he is said to have been addicted to Parisian fashion, and to have often style upon it, there can be little doubt that the influence of Canova was much more powerful, and that the softness, finish, and elegance, for which that eminent sculptor was so celebrated, were what Potton most anxiously endeavoured to realize; but whilst in these qualities he at the least rivalled Canova, he went far beyond him in that tendency to the sensuous and the voluptuous which was no less decidedly characteristic of the great Italian. The countrymen of Pradier were sufficiently accounted for, and many of them, no doubt, with a certain air of superiority. So "delicatamente voluptuosissime;" but to a colder English critic the delicacy often seems wanting, and while he cannot but admire the exquisite modelling of the form, he is constrained to turn with regret from what seems the perverse manner in which it is conceived.

From his return to France in 1819 down to his death, M. Pradier enjoyed a career of unbroken Parisian popularity; and during his later years, while all admitted him to be one of the most accomplished, by many he was regarded as the greatest of living French sculptors. Of the works by which he achieved and maintained his high position the following are some of the most celebrated—the dates are those of the years in which they appeared at the Exposition:—"Barberousse," executed 1826; "The Children of Niebe," 1822; "Psyche," 1824; "The Three Graces," 1831, now at Versailles; "Venus and Love," 1836; "An Odalisque," 1841; "Cassandra," 1843; "Phryne," 1845, well known in this country from having been placed in the Great Exhibition of 1851; "Sappho," 1849, a favour'd subject with him—there was a statue of Sappho in the Exposition the year of his death; "Spring," 1849: Hebes, Amazons, Pandoras (one of these is in the possession of Queen Victoria), the Achaeans, the Medallists, make up the list of that class of subjects in which he chiefly excelled, and which was most characteristic of his chisel. He also produced a large number of religious pieces, and many of them of considerable size, but out of France they have hardly reached a coloured figure in "Christ on the Cross," executed for Prince Demidoff; a "Pieta," executed in 1847, and now at Toulon; a "Marriage of the Virgin" for the Medallists, four "Apostles," a "Virgin" for the cathedral of Chartres, &c. Of portrait-statues he sculptured Gaston de Foix, Marshal Soul, General Damremont, Vendôme, Rousseau (for Geneva), Jouffroy (for Basancon), the Duc d'Orléans, &c. He also executed busts of Louis XVIII., Charles X., and other persons distinguished by their rank or social celebrity. Among his other works may be mentioned the tomb of Napoleon I., some fountains, vases, &c. He likewise modelled numerous small statues of a very meretricious character.

In 1822, he was made a Chevalier of the Legion of Honour. In 1827 he was elected Member of the Institute on the death of Lemot. He died somewhat suddenly on the 5th of June 1856. There were two or three casts after Pradier among the modern sculptures in the Crystal Palace at 1851.

PRAED, WINTHROP MACKWORTH, son of Mr. Sergeant Praed, was born in 1802. In 1820 a monthly magazine appeared, entitled 'The Etonian.' George Canning, while at Eton, wrote some clever essays in 'The Microcosm.' "The Microcosm" (afterwards Stanley Ford de Redcliffe) subsequently produced 'The Miniature.' These publications were regarded as exhibitions of youthful talent, were admired in a small circle, and forgotten. But 'The Etonian' at length found a publisher; it paid slight regard to the 'microcosm' of Eton, and presented no 'miniature' of its scholastic life; it gave vivid pictures of general society; it was bright with wit and poetry, with fun and satire. There was little of the boyish fun about it but of boyish life; it is the tale of the life of a boy named John in 'The Etonian' was Winthrop Mackworth Praed. From Eton to Trinity College, Cambridge. His career at the university corresponded with the expectations that had been formed of him. In 1822 he was a Browne's Medalist both for Greek ode and epigrams. In 1823 he obtained the Chancellor's prize for an English poem, 'Australia;' and in 1824 the same prize for 'Athens.' He was one of the first who read the school play of the famous Dillydally, Society—his most formidable rival being Thomas Babington Macaulay, 'The Etonian' was printed at the office of Mr. Knight, then editor of the 'Windsor News-paper,' and the intimacy that consequently arose led to the publication of 'Knight's Quarters Macaulay's' in 1824; in which Mr. Praed was one of the chief contributors, both in prose and verse. His poems are amongst the most original in our language; their wit and pathos are as remarkable as their finished elegance. A collection of some of these poems was published at New York in 1844, but it is far from complete; and those who desire that justice should be done to the memory of one of the most remarkable writers of his time, regret that these works, so often announced, should be so unaccomplished. Mr. Praed took his degree of B.A. in 1822. In 1829 he was called to the Bar; and in 1830 and 1831 was returned to Parliament for St. Germans. In the earnest and protracted conflicts that preceded the passing of the Reform Bill, he took a decided stand on the side of the Whigs. His life was full of events; full of events. In his speeches, as reported, exhibit a readiness of debating power rather than the flashes of wit which were expected from him. He was a most ardent supporter of the Whig administration, and it is far from certain that his vote for Mr. Canning in 1827, in his speeches, as reported, exhibit a readiness of debating power rather than the flashes of wit which were expected from him. He was a most ardent supporter of the Whig administration, and it is far from certain that his vote for Mr. Canning in 1827, in the controversy on the bill, was not the result of a wish to please his master and his party. In the event of 1832 he unsuccessfully contested St. Ives; but in 1835 he was returned to Parliament for Great Yarmouth. In that year he gave much of his time to the conduct of the Board of Control. He was subsequently member for Aylesbury, was Recorder of Barnstaple, and Deputy High-Steward for the University of Cambridge. Had Mr. Praed's life been longer spared, there can be little doubt that some of the most important offices of the state would have been within his reach; and his contributions to literature, like those of his friend Macaulay, might have carried forward the promise of his youth into new fields of excellence. He died on the 15th of July 1836, aged only 34 years.

PRASCOLITE. [MINERALOGY, S. I.]

PRASILITE. [MINERALOGY, S. I.]

PREROGATIVE COURT. One effect of the transfer of the jurisdiction of the Prerogative Court from the Court of Probate [Probatists, Court of, S. 2.] is, that the doctrine of the "notitia" has ceased to exist. This court, whose jurisdiction arose from the possession of bona notitia by the deceased person in two diocces, has consequently, although without formal abolition, altogether disappeared from our judicial system.

PRESCOTT. [LANCASTER.]}

PRESCOTT. [CANADA, S. 2.]

PRICE, REV. THOMAS, one of the most distinguished Welsh scholars of his age, was born on the 2nd of October 1757, at Pensereilin, in the parish of Llanafan Fawr, near Builth, in Brecknockshire. His father, the Rev. Price, had originally been a stonemason, but having at the age of seventeen found a place in the church, he was admitted to the sacred order by the abbot of Peterborough, and afterwards to the ordinary. He was the descendant of a long line of clergymen, who had acquired by incessant diligence and frugality the means of attending the college-school at Brecknock, and finally obtained ordination from the Bishop of St. Davids, and in 1784 the land he sought, after a course of twenty years. He was so fortunate as afterwards to be presented to three livings, but his income, like that of some other Welsh piutistels, was never believed to exceed fifty pounds a year. He had two sons, both of whom were educated to the church; the elder taking his degree at Oxford, while the younger, William (Canning of Stran- ford de Redcliffe) subsequently produced 'The Miniature.' These publications were regarded as exhibitions of youthful talent, were admired in a small circle, and forgotten. But 'The Etonian' at length found a publisher; it paid slight regard to the 'microcosm' of Eton, and presented no 'miniature' of its scholastic life; it gave
French. In 1813 he received holy orders, and in 1825, after performing for thirteen years the duties of various curacies near Crickhowel, he was appointed to the vicarage of Cwmmo. This was his last preferment. The rest of his life was passed in the pursuit of professional labour, and in a great variety of voluntary pursuits. Mr. Price carved in wood, modelled in wax and cork, etched with some skill, could play on the Welsh harp by ear, and had the honour of presenting a harp from his own invention to Queen Charlotte on Palais-Royal in 1843. He made a great number of drawings, some of which were engraved as early as 1809, in his friend Theophilus Jones’s ‘History of Brecknockshire’. He was a great promoter of the Eisteddfods, or meetings for the cultivation of Welsh literature, and received much applause for the manner in which he donated most of the prizes. He was looked up to by most of his countrymen with enthusiastic admiration as an accomplished champion of his country’s language and literature. His health began to fail somewhat early, and he died at Cwmmo on the 7th of November 1846.

The best of his English works are collected in the ‘Literary Remains of the Rev. Thomas Price, with a Memoir of his Life by Jane Williams, Ysgafell’, 2 vols., Svo, Llandovery, 1854-55. The first volume contains an account of a ‘Tour through Brittany’, made in the summer of 1829, written in a lively and agreeable style, and peculiarly interesting as containing the observations of one familiar with the language and literature of Wales on the kindred language and literature of the French, together with a view on the condition of the Remains of Ancient Literature in the Welsh, Irish, and Gaelic Languages; ‘An Essay on the Influence which the Welsh Traditions have had on the Literature of Europe;’ ‘A Critical Essay on the Language and Literature of Wales from the Beginning of the Eleventh to the Beginning of the Fourteenth Century’ (in the fourteenth, make up the remainder of the first volume. The second is entirely occupied with Miss Williams’s memoir, which is enlivened with some interesting correspondence, and presents the fullest picture that has yet been drawn of a Welsh literary life. By far the greatest part of Mr. Price’s literary labours were in his native language; he was a contributor to fifteen Welsh periodicals, for the encouragement of which he made a rule, once a month, to write an article on some subject. He was one of the most eminent scholars of his time that would now be impracticable to form a collection of the whole. His favourite signature however was ‘Carnhuanawc’ (‘Man of the Sunny Mound’), which was familiarly known to every magazine-reader in Wales. He was a great naturalist, and his work in Welsh on the natural history of Wales, ‘Hanes Cymru a chenedl y Cymry o Cynoesod y hyd ar Farwolch llewelùn ap Gryfudd’ (‘History of Wales and the Welsh Nation from the Early Ages to the Present Day’), where he proved that the country was united with England. It was published in numbers, sometimes with long intervals, the first of the fourteen of which it consisted appearing in 1836 and the last in 1844, the whole forming a volume of about 900 pages. It has been translated into English, and is reprinted, and is the best work on the condition of the Welsh country extant in any language, and it is somewhat singular that no translation has yet appeared in English. The omission may serve in some degree to justify the complaint which Mr. Price was accustomed to make of the extraordinary neglect of Welsh literature and total ignorance of British History prevailing in England, and the consequent contempt evinced by the English for everything relating to Wales, in contradiction to the high appreciation of Welsh literature among Welshmen and the superior knowledge and desire for information on all subjects connected with the principality by German scholars.

On the subject of his native language Mr. Price was so enthusiastic that his feelings sometimes outran his judgment. At the Eisteddfod at Whelba in 1834, he exclaimed, in an oration in the Welsh language, ‘We are told our language cannot last; but let them inform us what language will last, and we will answer them by making it last. We are not prepared to goad to it—when we are taunted with the extinction of our native tongue—shall we not reply! shall we not say that we likewise perceive the seeds of decay in the English? With the same energy with which we present the English asleep with the Latin, the Saxon, and the Norman French, let our mountain tongue may yet rouse some remains of the Britons to patriotism and glory.’ Most Englishmen, we believe, who have urged the adoption of the English language in Wales, have supported the measure not on the ground of its supposed superior duration in the future, but of its evident superior usefulness in the present.

A notice of Mr. Price’s, to which he appears to have attached considerable importance, was, after communicating it to the ‘Journal of the Asiatic Society of India’, 1828, published the subject of a separate communication, ‘The Geographical Progress of Empire and Civilization’ (Llandover, 1847-49). Every one is familiar with the idea of the ‘western progressive movement’, and Mr. Price was a prominent member of that. Mr. Price fancied he had made a discovery, ‘that the average rate of progress corresponds with that of the retrogradation of the equinoctial points, which is 50 seconds and a fraction in a year; and a voluntary movement is subject to periodic retardations and accelerations.’ ‘The focus, or pole, was in 1847,’ according to his speculations, ‘located in the northern portion of this island, near the Firth of Forth in Scotland, moving in the direction of the Solway Firth at the rate of four miles a year.’ All the whole, Mr. Price’s works are more remarkable for vigorous, animated, and learning, than for sound judgment.

PRICHARD, JAMES COWLES, an eminent ethnologist, was born at Ros in Herefordshire in the year 1795. He was educated for the medical profession, and took his degree of M.D. at Edinburgh. He chose for the subject of his inaugural thesis the physical history of mankind. This seems to have determined the current of his thoughts throughout his whole life. ‘The Natural History of Man,’ published with his professional duties, he still kept the subject of his inaugural thesis before his mind, and in 1813 he published his ‘Researches into the Physical History of Mankind.’ This work, which was originally published in one volume, reached a second edition in two volumes in 1829, and a third edition was finished in 1849, extending to five volumes. From the period of the first publication of this work it took the first rank amongst ethnological works, and the last edition, with the corroborative narrative of that that has hitherto appeared upon the physical history of man. Dr. Prichard, whilst an anatomist and physiologist, was one of the first to avail himself of the study of philology as a means of arriving at the history of the various races of man. His contributions to ethnology took a variety of forms. In 1832 he read an elaborate paper to the British Association, then assembled in Bristol, ‘On the Application of Philological and Physical Researches to the History of the Human Race.’ As a result of this he published ‘Researches into the physical history of man under the title of ‘The Natural History of Man.’ A second edition of this work appeared in 1845, and it has been translated into the French and German languages. He has likewise written almost every paper in the scientific periodicals to which he contributed. The twelfth volume of the proceedings of the Zoological Society is a paper ‘On the Crania of the Laplanders and Finns.’ He also published a work ‘On the Eastern Origin of the Celtic Language,’ in which he pointed out the relations between the Celtic language and the great group of Indo-Germanic languages derived from the east. Another work also arose out of his ethnological researches, which was entitled an ‘Analysis of Egyptian Mythology.’

All of great and important department of science, Dr. Prichard was not inattentive to professional studies. His ethnological and philological reading naturally led him to contemplate man psychologise generally, and he addressed himself successfully to the study of the nervous system, and the results of its deranged condition on the mind of man. In 1828 he published a work ‘On the Diseases of the Nervous System.’ This was followed by a ‘Treatise on Insanity.’ In this work he proposed a classification of attacks of insanity, and speedily became recognised as one of the first authorities on the subject of mental derangement. He was appointed visiting physician to the Gloucestershire Lunatic Asylum. He subsequently published a work ‘On the Nature and Treatment of Manias’ and his labours connected with insanity led to his appointment as one of the Commissioners of Lunacy in 1845. On this occasion he removed from Bristol to London, where he continued to reside till his death. Besides the works already
mentioned, Dr. Pritchard enlarged an essay which he had before the Philosophical Society of Bristol into a work entitled "A Review of the Cyclopedia of Practical Medicine." He was also an extensive contributor to the 'Cyclopedia of Practical Medicine.' He was made M.D. of Oxford on the occasion of the installation of the Duke of Wellington as chancellor of that university. He was president during one session of the meeting of the Incorporated Society of Apothecaries held at the old Hall, now the Bristol Medical Association. He was president of the Ethnological Society, and published an anniversary address delivered before that society. He was a Fellow of the Geological Society, and a member of the more scientific societies in this country and on the Continent. He died in London, December 22, 1845, of an attack of rheumatism complicated with pericarditis.

PRIESSNITZ, VINCENZ, the founder of Hydropathy, or the treatment of disease by baths, was born on the 4th of October 1799, at Gräfenberg, in Austrian Silesia, where his father was a farmer. He received only a small amount of ordinary education at the town-school of Freistalau; for his elder brother having died, and his father become blind, he was obliged at an early age to assist his mother in managing and working the farm. He continued in this employment several years; but one day, when he was taking some sacks of barley to the fields for sowing, the horse became restive, seized the driver's cap and dragged the loaded cart over him, broke two of his ribs. A medical man, after examining him, expressed an opinion that the injuries sustained were so great that, even if he recovered, he would be a cripple for life. Priessnitz, however, by perseverance and self-discipline, enabled himself to expand his chest to the utmost extent, replaced his ribs, and by the free use of cold water kept down inflammation; so that in a short time he was enabled to return to his work. The prospect of a cure by cold water, which had been so beneficial in his own case, was successfully used in other cases of inflammatory disorder. His reputation gradually extended; he studied medical books, formed a sort of system of medical treatment, established cold-water baths at Gräfenberg, and afterwards at various other places in the distant parts of Germany. In 1829 his system may be said to have been in full operation, and from the first of January of that year till the 1st of January 1844 the number of his patients had amounted to 5672. The total number of his patients in 1844 was 1000, and the number of both sexes and all ages generally present at Gräfenberg was about 360. No particle of medicine, vegetable or mineral, no tonic, no stimulant, no emetic, no purgative, was ever administered in any manner whatever, except water, which was never once, with or without the assistance of the patient employed. Water variously applied, externally as well as internally, the process of sweating, fresh air, out-door exercise, plain diet, regulated clothing, early hours, and cheerful society, constituted the only remedies. This system contains a system for the treatment of diseases which occurred on the 28th of November 1851, at Gräfenberg. The disease of which he died is stated to have been dropsy on the chest. Hydropathic establishments are now in being in various places on the Continent of Europe, in the United Kingdom of Great Britain and Ireland, and on the continent of America.

Priessnitz did not write any medical work himself, but accounts of his system have been published in German and English. Captain R. T. Claridge in 1842 published 'The Water-Cure, or Hydropathy, as practised by Vincent Priessnitz, at Gräfenberg, Silesia, Austria,' 5vo, London; and 'Every Man his own Doctor: the Cold Water, Tempid Water, and Friction Cures, as applicable to all diseases which the Human Frame is subject to, and also to the Cures of Diseases in Horses and Cattle,' 5vo, London.

(Vincenz Priessnitz, eine Lebensbeschreibung, von Dr. J. E. M. Selinger, 12mo, Vienna, 1852.)

PRINCE OF BOROUGH, [THE HON. HAMMBURGH.] PRINCIPLES OF BOROUGH, [THE HON. HAMMBURGH.]

PRINTING, INVENTIONS IN. Since our account of Cowper and Appleth's machine for printing 'The Times' newspaper ['Printing Machine, vol. xix. p. 151], a number of improvements have been introduced. Steam power has also been added to the machine. The Stanhope press, in which the machine, of a form of type at each end, moves backward and forward under the platen, which gives the impression to one form while the other is being inked by the jet of ink; and the type is of a size which for a time supposed to be adapted for the finer sorts of book-work; but the process was very much slower, and the
In this machine a central drum 200 inches in circumference, or 66 inches in diameter, turns on a horizontal axis. We copy the following description from C. Tomlinson's 'Cyclopedia of Useful Arts and Manufactures.' "The inking-table and the columns of type are secured to the surface of this drum; the columns of type are placed vertically, not being parallel to the axis of the drum, but turned in the following manner. A slab of iron is curved on its underside, so as to fit the large cylinder, while its upper surface is fitted into facets, or flat parts, corresponding to the size of each letter of the columns of the newspaper; between each column there is a strip of steel, with a thin edge, to print the 'rule,' the body of this strip being wedge-shaped, so as to fill up the angular space left between the columns of the type, and to prevent the type from falling in other ways, or in the direction of the lines; the type is pressed together in the other direction by means of screws, and is firmly held together. The surface of the type thus forms a portion of a polygon, as already noticed; and the regularity of the impression is obtained by pasting slips of paper on the paper cylinder. The large central drum is surrounded by eight cylinders, each about 13 inches in diameter, also with vertical axes. They are covered with cloth, and upon them the paper to be printed is placed in contact with the type cylinders. Each is so connected with the central drum, by means of toothed wheels, that the surface of each must move with the same velocity as the surface of the drum. It will thus be evident that the type must be moved eight times during one revolution of the drum. This is accomplished by means of eight sets of inking rollers—one for each paper cylinder. The ink is held in a vertical reservoir (supplied from above), formed of a heavy roller-agate which rests the two straight edges connected at the bottom, so as to project into the features of the inking rollers. It is conveyed from the doctor-roller by one of the inking rollers in the following manner:—As the inking-table on the revolving drum passes the doctor-roller, it receives from it a coating of ink, and then coming immediately in contact with the inking rollers, it inks them, the type next follow and receive from the inking rollers their coating of ink, and the drum still revolving brings the type into contact with the paper roller, and the sheet is printed. It must not be forgotten, as one of the distinctive features of this machine, that the various processes which have just been enumerated for one set of inking rollers, and one paper cylinder, are repeated eight times for every single revolution of the drum. Thus a whole sheet of paper is printed, and turned out of the machine. For this purpose it is necessary to supply the eight cylinders each with a sheet of paper. Over each cylinder is a sloping desk, upon which a piece of white paper is placed. The layer-on stands by the side of this desk, and passes forward the paper a sheet at a time towards the tape-fingers of the machine. These tapes seize it and draw it down in a vertical direction, between tapes, in the eight vertical frames, until its vertical edges correspond with the position of the form of type on the drum. When in this position its vertical motion is arrested for a moment, then it moves horizontally, and is carried towards the printing cylinder by the face of the drum. Passing round this cylinder it is instantly printed. It is then conveyed horizontally, by means of tapes, to the other side of the frame, and is moved along to another desk, where the taker-off pulls it down. As soon as one sheet is thus disposed of, accommodation is made for another; and as each layer-on delivers to the machine two sheets in five seconds, sixteen sheets are thus printed in that brief space, and this is continued for any length of time, supposing no accident occurs, such as a sheet going wrong, in which case it is the duty of the taker-off to pull a bell-handle, and the machine is stopped. As the type-form on the central drum moves at the rate of 70 inches per second, and the paper to be printed moves at the same rate, if any error in the delivery and method of the paper arrives, the result is a 70th of a second too soon or too late, the relative position of the columns on one side as compared with those on the other side of the paper will be out of register by 1-700th of 70 inches, viz., one inch; in which case the edge of the printed matter on one side will be an inch nearer to the edge than on the other side. It is only by an accurate setting of the machine that it has to do, is to draw forward the sheets so as always to have the edge of one ready for the machine to take in. If the steam-engine which works the machine be put on a greater speed, the central drum, and all the attendant parts would move with a motion so rapid and such a speed might easily be obtained as to render it impossible for the layers-on to present the paper fast enough to satisfy the improved appetite of the machine; but in any case it must be kept moving so that the hands must be kept on close to present them; but only at those periods, rapidly recurring though they be, which are provided by the peculiar functions of the machine."

This machine, with certain modifications to adapt it for printing on a large size, has been used for the 'Illustrated News,' and was shown at work during the Exhibition of 1851; it has also been adopted in other instances where rapidity of production was necessary. Another machine, likewise on the same principle, has been invented by the Messrs. Hoe, of America, and several of these have been brought into use in London. The inventive faculty has also been applied to methods for facilitating the arrangement of the type, though with far less success. Mr. Knight, in his work on Printing, and, also, at the Paris Exhibition of 1855, Mr. Knight says:—"During the last twenty years there have been various attempts to produce a machine that will, to some extent, supersede that portion of the work which is done by the printer himself. Without attempting to describe the various contrivances by which a more rapid method of arranging moveable types was to be effected than by the ordinary method, it may be sufficient to say that by keys, like those of a pianoforte, some force might be applied to remove a single letter from its proper receptacle, and arrange it in a combination of words and sentences. In the ordinary method, the various types which are necessary for the usual language lie in separate cells before the compositor, those most in use being nearest the compositor. He has only to make his selection, which, picking up letter by letter, he forms words, putting spaces between each word. As he approaches the end of his line, he finds that the next word is too long to come within the line, and he therefore divides it by a hyphen or carries it over to the next line. Then he spaces out the words, so as to make the line fit closely, but not tightly. Now it is evident that if the most perfect instrument could be made to pick up the letters and spaces, the intelligence of the workman would be rendered as unnecessary as that of the person who, in printing a newspaper, is called of each line. Hence every composing-machine must be an imperfect instrument."

But, nevertheless, it may in some cases be of the utmost importance to have the quicker manner of setting the type more rapidly than by the fingers. In a trial of comparative expedition between the logographic system of Major Bemiowski, and the common mode (in which trial Mr. Rennie was referee), it was found that a compositor at Mr. Clay's printing-office picked up and justified 8000 letters in two hours and twenty minutes. He distributed or returned the same when used, to the case in fifty-one minutes. There were several composing and distributing machines in the French Exhibition, but the most remarkable one, and that which appears to me, as it appeared to M. Didot and other competent judges, to approach nearer than any other invention to the accomplishing of this long sought for object, is thus entitled—'Machine a composer et metre bas pour l'usage de Dimpriming, composé et exécuté par Christian Sirenen.' It was stated that a Copenhagen newspaper, of which a copy was shown, had been printed for some time by this method. It would be impossible to convey an adequate notion of the details of this machine without drawings. I will endeavour briefly to state the principle:—"The type are of the usual thickness and height. In the centre of each type, in the front, is a deep nick of a dovetail shape, which fits on to a metal edge, so that the type cannot be displaced. But of 111 letters in all, there are only three or four, cut at right angles, the nicks of no one letter being the same as another. A cylinder, which may be described as a large basin, has a number of metal edges placed vertically in its sides, upon which the types without any regard to order, but being the matter for distribution, are rapidly said by the dovetail nick.
When the basin is filled, it is inverted upon a cylinder of corresponding size below. Upon the rim of this cylinder is a separate opening for the reception of each of the 111 letters, but no one opening is like another. The distributing and receiving ends of the separate letters are each of them represented by a small aperture. The composition is seated; with a tredle he moves the upper cylinder, which, as it slowly revolves, finds in the lower cylinder, which is stationary, a fit place for every separate letter as it descends by its own gravity to the bottom of each metal edge. The m having four sides cut and two transverse slits into its own division, and cannot be confused with the n.

"But whilst this process of distribution is steadily proceeding, without any care but to keep the upper cylinder occasionally supplied with new material for its operation, the process of composition is rapidly going on. The compositor sits before a compact little frame of keys, each key having a connecting wire for each division of the lower cylinder. He strikes a key and the lower letter is instantly detached and falls into a funnel-shaped receptacle below, where, without being inverted in any way, it runs into a groove, and arranges itself in its proper order, in the line of its fellows. This is a long line of several feet. By an ingenious contrivance each line is passed on one side, as it is completed, to another workman, who puts it in order with the due width of his page or column, and spaces out the words in the ordinary way. I saw 1000 letters thus placed in line in the short space of four minutes, and the spelling and punctuation appeared as correct as in most matter of composition of ordinary length. The rapidity in rendering the loss of time in refilling the cylinders, and through other hindrances, is taken into account, it was stated by the exhibitor that 80,000 types are set up and distributed each day. This gives a rate of about 1000 an hour, which is treble that of the ordinary compositor’s rate.

The interest connected with the question of ‘Types for the Blind,’ to which considerable impetus was given by the Society of Arts for Scotland at Edinburgh, which offered their gulden prize of 100 guineas to the best type, is greatly to bring about a change in the intellectual education of the blind. The publication of the article Bunsen in the ‘Penny Cyclopaedia,’ at a time when the minds of many were thus directed, and the strictures therein contained on the absence of intellectual training in most of the asylums, also rendered essential benefits on this point. Dr. S. G. Howe, of Boston in the United States, in 1833 contrived an alphabet, founded upon that of Haly, of a very compact form and shape, by which it could be printed with great facility, and is now in general use in America. The late Mr. John Alston, the treasurer of the Glasgow Asylum, then no man connected with the blind deserves more honourable mention, contributed greatly to this educational movement; for more than one registrar of wills or less arbitrary, the evil would necessarily follow of isolating the blind by putting them in a position to require special teachers. He therefore adopted the plain Roman characters deprived of their small extremities—the same serif of type-founders; and, finding that it could be easily read, that it would also enable any seeing person who could read to be a teacher of the blind, he at once procured founts of type, and published several works in raised letters; the success of these for the benefit of the blind is well known. The most important of these is now in the possession of the British Institute in Paris. Having thus laboured for several years, he visited more than once the principal asylums for the blind in the kingdom. In his work ‘Statements,’ &c. published in 1846, he says, that after the introduction of his system, ‘I found a considerable improvement. Subsequently I visited the English institutions a third time, and found a very great number who could read with ease and intelligence; and I have reason to know that there are some hundreds reading the ‘type language’ who could not read at all the characters of the whole of the Bible in raised types; thus in a short time showing the sufficiency of the system placed before the public.’ It may be added, that Mr. Alston also brought out some beautiful embroidered muslins and maps, and that he published a ‘New Testament’ in official type; the size of type being only 32 and 4to. The paper used for these works is strongly sized, to retain the impression. In order to account for the great extent of the Bible, it must be borne in mind that the paper can only be printed on one side, and that the letters require to be of considerable size in order to be distinct to the touch. The printing is effected by a copper-plate press. The type is being strongly relieved, and liable frequently to give way under the heavy pressure required, it was necessary to have the type made in one piece, in order that the progress of the work. The whole of the works were composed in the printing shop of the Glasgow Asylum, a man and a boy acting as compositors, there being one pressman, and the ordinary teacher acting as corrector of the press. These books are now used in the most of the Edinburgh asylums for the blind, and in the United States and Scotland. The success which has attended Mr. Alston’s exertions was a new assurance to the Society of Arts for Scotland that they had acted wisely in regarding the steno- graphic and typographical characters, as well as the angular modifications of the Roman alphabet, as reclaimably.

An invention by Alois Auer, of Vienna, called ‘Natur- selbstdruck,’ deserves mention. By it impressions are taken from the natural objects themselves, and by an ingenious process brought into a form fitted for printing from. Some of the specimens produced, such as the veins and markings of agate-stones, are of remarkable clearness and beauty. The invention, with some improvements in the process, has been patented by Mr. Henry Bradbury, and the ‘Pern Flora of the United Kingdom,’ produced by him in a folio volume, with 51 plates, is a proof of its capabilities of affording all the advantages of a herbarium, without the defects; as well as to its being available for many other branches of natural history.

In type-founding also an ingenious machine has been invented. In this, by turning a crank-wheel, the metal is injected with considerable force into the type-mould, brought by the machinery in front of a reservoir of metal kept fluid by a gentle current of air. The metal being thus forced out and delivered off it, at a rate varying from six to ten times the rapidity with which the operation can be performed by hand. Both in casting by hand, and in the machine, the moulds are liable to become obstructed by particles of the metal remaining, when it has to be brushed clean. When this happens to the machine, it ceases to act, and thus at once informs the operator of the defect.

PRIVY COUNCIL. [JUDICIAL COMMITTEE, S. 9.]
PRONOUNCED CORRECT. The registering letters of administration of the effects of persons dying intestate, and probate of the wills of testators, which was formerly the prerogative of the Ecclesiastical Courts [Ecclesiastical Courts, S. 5, p. 603: has by a recent statute (30 & 21 Vict. c. 77) been vested in a newly established court, called the Court of Probate. The functions of this court are confined entirely to deciding upon the authenticity of wills, and upon the proper persons to whom administration is to be granted. It has jurisdiction over the property of deceased persons, and the rights of the various parties who claim it beneficially, the court has nothing to do. These matters must be decided by the courts of law and equity, as before the passing of the Act. The duties of registrars under the Act are to receive applications for the appointment of the personal representatives of deceased persons. A central registry of wills and administration is established in London, and district registrars are established in forty of the principal towns of England. The office or registry in which probate or letters of administration are to be sought, is no longer determined by the locality of the assets of the deceased person, but by the place where the deceased had a fixed abode at the time of death. Should the testator or intestate have a permanent place of residence in one of the registry districts, the application for probate or administration may be obtained at the registry of the district. The executors or parties claiming administration may, if they think fit, apply to the principal or metropolitan registry for probate or administration, and this may in some cases be found more convenient than applying to the district registry. Original wills proved in the country will be preserved in the district registries; but copies of them will be transmitted to the principal registry in London, so that in most cases the same copy will serve for the purpose.

The practice of the Court of Probate in all contentious matters is thrown open to the whole legal profession, so that the monopoly of testamentary business enjoyed by advocates and solicitors is abolished.

The court is presided over by a single judge, who sits at Westminster. An appeal from his decision lies direct to the House of Lords.

- In cases where a person died in one of the forty districts,
leaving personal property under $300, and real property under $300; the County Court of the district has jurisdiction should any contention arise. From the decision of the County Court judge, an appeal, which is final, lies to the Court of Probate.

One principal advantage of the new system lies in the remarkable increase in the quality of the probate, which equals the improvement in the question of bona nova notabilia, and the necessity of obtaining prerogative probate or administration was founded. The rules of evidence in the Court of Probate are to be the same as those in courts of law and equity, where declaratory proceedings are either admissible to those of the courts of common law.

PRODUCIÆ, a family of Brachiopodous Molusco, including the genera Productus, Strophopala, and Chonetes. The shell consists of two valves, arranged in a straight-hinge line; valves rarely articulated by teeth; closely appressed, furnished with tubular spines; ventral valves convex; dorsal concave; internal surface dotted with conspicuous funnel-shaped punctures; dorsal valve with a prominent cardinal process; branchial processes (f) subcentral; vascular markings lateral, broad, and simple; adductor impressions denticulate, separated by a narrow central ridge; ventral valve with a slightly notched hinge-line; adductor sac central, near the umbo; cardinal impressions lateral, striated.

Productus has the shell, oval, arculate, beak large and rounded; spines scattered; hinge area in each valve linear, indistinct; no hinge-teeth; cardinal process lobed, striated; vascular impressions simple, curved; ventral valve deep, with two folds; dorsal valve entire.

The species are all fossil. There are about sixty species. They are found ranging from the Devonian to the Peruvian rocks of North and South America, Europe, Spitsbergen, Tibet, and Australia.

Strophopala has its shell attached by the umbo of the ventral valve. There are 8 species.

Chonetes contains 24 species, which are found fossil from the Silurian to the Carboniferous rocks.

PROME. [HRMA; PIIH, S. 2.]

PRONGBUCK. [ANT.]

PROPOLIS. [BEE.]

PROXYLITE. [Sylvis, S. 2.]

PROTECTION ACTS. The object of these statutes is to enable a debtor in insolvency circumstances to avert or forestall the impending danger of imprisonment; for any person not a trader within the Bankruptcy Acts, or who, being a trader, owes less than $300, whether in prison or not, may apply in London to the Insolvency Court, in the county to the County Courts, for protection from process. A schedule of debts, and of the names of his creditors, must accompany the petition; which must set forth an account of his whole estate and affairs. The insolvency court determines the effect the petition has on the debtor’s discharge. The presentation of the petition vests all the petitioner’s rights in the registrar, who, as official assignee, proceeds to possess himself of all that can be obtained without suit. Notice of the petition is given to the creditors, and inserted in the ‘Gazette’ and local newspapers, a public sitting of the court being at the same time appointed for the first examination of the petitioner. If it appear that the allegations in the petition and the matters in the schedule are not true, or that the debts do not have been contracted fraudulently or improperly, and do not arise from any of the acts of misconduct enumerated in the statutes, a day is fixed on which a final order shall be made, unless cause be shown to the contrary. If made, its effect is to permanently protect the petitioner from all process, in respect of the debts due, at the time of filing the petition, to the creditors named in the schedule. On the other hand, if cause is shown, the court may adjourn the consideration of the final order sine die.

At any time after the final order, the assignee of the estate may claim property since acquired by the insolvent, which claim may be summarily enforced by the order of the court. So that under the Protection Acts, as in the case of an insolvent, the assignee in bankruptcy as well as the insolvent debtor may be applied in payment of his debts. In this consists the great distinction between the relief afforded by the bankrupt laws to a trader, and that obtainable by an insolvent debtor, or a petitioner under the Protection Acts.

(Blackstone’s Commentaries, Mr. Kent’s edition, vol. ii, p. 516.)

PROUT, SAMUEL, was born on the 17th of September, 1783, in Plymouth—the birthplace of so many English painters. From earliest childhood he was noted for an irrepressible spirit of observation and enjoyment, which, with the genius and the power of an artist, formed the subject of a design by him, and the passion increased with his years. His associate in his early artistic studies was Benjamin Haydon, but instead of yielding to the eager impulses after an unattainable gardeur of his enthusiastic friend, young Prout contended himself with unceasingly sketching from nature the ivy-mantled bridges, mossy water-mills, and rock-built cottages, which characterise the valley scenery of Devon.

Whilst uncertain as to his future course, he had the good fortune to be introduced to Mr. John Britton, the antiquary, then at Plymouth on his way to collect materials for an account of Cornwall, which he was preparing for the ‘ Beauties of England.’ [Britton, John, S. 2.] Mr. Britton, pleased with his sketches, proposed that he should accompany him to Oxford and London, which he accepted the offer. The portfolio of Cornish drawings which he afterwards transmitted to Mr. Britton, excited by their boldness of style considerable notice, and the young artist was easily persuaded to remove to London.

He arrived in London in 1805, and found an admirer and patron in Psler the printseller, then residing in the Westminster-road and afterwards in Street-street, who used readily to purchase his water-colour drawings, and dispose of them among his customers. Prout had a great deal of time to devote to these works, but Prout had the good sense, on comparing his pictures with those of the established artists, to recognise his own deficiencies; and he was well pleased to be thus enabled, by means of unambitious drawings, to support himself whilst making a valuable effort to extend his artistic knowledge and executive skill. During these years he painted marine views, especially coast-scenes with fishing-craft, more than architecture, for which a very decided inclination had not yet developed itself. He spent so much time to teaching, and he staked some lessons and studies for the use of teachers and pupils; but perceiving the capabilities of the newly-introduced art of lithography for yielding fac-similes of the painter’s pencil-sketches, he began early to draw on paper, which he afterwards transferred to stone, and on which he did, with great facility. He published in 1816 a series of ‘Studies’ which met with great success, and was followed by ‘Views in the North and West of England.’ Progressing in his art, he published a series of drawing-books, which by their vigour of drawing and brilliancy of effect raised that class of publication far above the estimation in which it had been previously held, and did much to extend the reputation of the artist.

Mr. Prout had already secured a high position when he was led in 1818—partly in the hope of restoring his health, which had become much enfeebled, but also with a view to turning professional account the taste for foreign scenery indicated by the frequencies of continental travel, and the return of peace—to make a tour in France. The quaint street-architecture of Rouen, and the civic and ecclesiastical structures of other Norman towns, seemed to reveal in him an entirely new sense. From this time he gave himself, with undivided zeal and unapproached success, to the delineation of the weather-worn and mouldering remains of medieval architecture. Year after year he continued to journey through the fairest parts of France and Switzerland, and of Germany, to the many places that still bore the marks of northern Gothic buildings that attracted his pencil, or those tumble-down heavy-gabled domestic houses which, though hardly ranking among any of the architectural divisions, had in his eyes an equal attraction in their antique picturesque-ness. This was the period that the author of ‘The Kestrel’ permitted him to publish a handsome folio of lithographic ‘Fac-Similes of Sketches made in Flanders and Germany.’ This was the first of the numerous series of lithographic copies of painters’ finished sketches which have added so greatly to the enjoy-
PROT had correctly appreciated the importance of chemistry, in explaining the functions of living beings, and that he was the first physician who sought to apply the doctrines of modern chemistry to the explanation of the phenomena of disease. He was an exceedingly careful and accurate experimenter, and with regard to some of his conclusions, which were at one time considered erroneous, a more careful investigation has confirmed the truth of his views.

Dr. PROT was one of the gentlemen chosen to write the "Bridgewater Treatises." The subject of his essay was "Chemistry, and the Function of the Vibrating Retina, as considered with reference to Natural Theology." This work abounds with evidence of his profound knowledge of the laws of chemistry. Although principally occupied with chemistry in relation to his profession, he took an interest in all sciences and in all branches of his favourite science. He was one of the first to analyse the so-called Coprolites, and to discover the large quantity of phosphate of lime they contained. This he did in a paper published in the third volume of the Transactions of the Geological Society. The paper was entitled "On the Analysis of the Fossil Fossils of Ichthyosaurus and other Animals." Dr. PROT was a Fellow of the Royal Society, and many other learned societies. He died at his house in Backwell Street, London, near the botanic garden, in the 9th of June, 1839, in the 60th year of his age. He was a man of exceedingly retiring habits, and greatly respected by those who knew him intimately.

PRUSSIA. The area and population of Prussia and its Provinces are as follows:

PSAMMA, a genus of Grasses belonging to the tribe Arundinaceae, is known by its flower being enveloped in long silky hairs, the lower glumes shorter than the upper, and its panicle being spike-like.

P. armeria, Sea- Reed, Maram, is the only British species. It is found on sandy sea-shores, where its roots assist in binding the shifting sands.

PSOLID. Equisetum, a small Equisetum, in the order Holohuridaceae. The only British genus included by the late Professor E. Forbes in this tribe, is Psolus, which is thus characterised:—Body irregular, asciiform; suckers in five rows, three only of which are developed and placed on a soft foot or disk; tentacle with' large, uniseriate, cirrate hairs.

P. phantopus (Holohuridura phantactus, Linnaeus), the Snail Sea-Cucumber, is an inhabitant of the British Seas. It is of a brown colour, has the head reddish-white with orange spots and orange tentacles, the body covered with pustulated scales, or ridges. It adheres to substances with great firmness by means of its ventral disk. "So powerfully does it adhere," says Professor E. Forbes, "that I have known the head of the animal carried away by the dredge when it brought up entirely every other foreign body that was in contact with it." It is found in European seas, and the genus ranges to the Indian seas. Professor Forbes says, "the Psolus teresornia of Jager and Lesson, should form the type of another genus, distinguished by its twenty tentacles. The genus Equisetum should be united with Psolus." (Forbes, History of British Star-Fishers.)

PUBLIC HEALTH. The general interest taken by all classes in whatever concerns the public health, and the still growing desire for a supply of pure water, is in this year, evident, which form so marked a characteristic of the present age, may be said to have received their earliest impetus from the "Inquiry into the Condition of the Working Classes," which resulted in the passing of the Poor Law Amendment Act of 1834, and of the Act of April 1856, for the formation into existence by that Act. The Commissioners appointed to conduct the preliminary inquiry were made conscious of a state of things connected with the dwellings of the working
classes, their social circumstances, and their physical condition generally, far more unfavourable than they had previous to the observation, and conditions which appeared in their Report produced a strong impression on the public mind, already startled by the dread march of Cholera. When the Poor Law Amendment Act was brought into Parliament, the observations of the Commission were published in the Annual Reports of the Commissioners, deepened and strengthened this impression, and led to a desire for a fuller and more specific investigation. Such an investigation the Poor Law Board determined to undertake early in 1842, and the first step was the appointment of the Metropolis, being entrusted to Dr. Arnott, Dr. Kay, and Dr. Southwood Smith. The Reports of these gentlemen, which were printed in the Fourth and Fifth Annual Reports of the Poor Law Board, were published to check the supplies of the districts, vice, misery, and disease, as the direct and almost inevitable result of the neglect of the plainest and most rudimentary sanitary laws. The statements of the Commissioners, as might be expected, excited a very painful sensation, and the then Bishop of London (Dr. Blomfield) moved in the House of Lords (Aug. 19, 1839) an address to her Majesty, praying that a further inquiry might be made as to the disease and destitution prevalent among the labouring classes in certain districts of the metropolis; how far the same prevailed in other parts of the country, and what relief could be afforded to the distressed. The House resolved that an inquiry should be held, and the result of the inquiries made by the Board, the local investigations were carried on mainly through the medium of the Assistant Poor Law Commissioners, and the medical officers of Unions, but much assistance was derived from the medical profession generally, the clergy, and others; and the large number of information the Board were brought together of a kind similar to that previously obtained by the Metropolitan Commission. This information was arranged and digested by Mr. Edwin Chadwick, then Secretary to the Poor Law Board. His Report on the General Sanitary Condition of the Labouring Classes in Great Britain, printed in 1842, presented not merely the fullest and most complete view that had been brought before the public eye of the physical and social condition of the labouring classes throughout the country, the causes of the prevalence of endemic and epidemic diseases, and the clearest and most comprehensive suggestions for remediating the evils shown to be so widely prevalent, but from it may be dated the origin of those important measures of sanitary reform which we shall presently have to notice, and which were in fact here firmly sketched. We must not, however, omit to mention, in noticing these pioneers of sanitary improvement, the very important statistical researches of Dr. James Stawell and Mr. John Snow, which were carried on simultaneously with the inquiries just described, which have been continued to the present day, and which have served, and still serve, to give precision and specific direction to the operations of the other inquiries.

In the Report of Mr. Chadwick, it was shown that whilst in each there were local and peculiar causes of mischief, in all the great towns there were common sources of danger and disease, in the existence of close and confined localities where the over-crowded houses were immediately constructed, undrained or insufficiently drained, damp, dirty, and ill-ventilated, and surrounded with numerous sources of malaria; the seats of almost constant fever and sickness, and that, as a consequence of the impaired physical condition, the inhabitants were the earliest and most susceptible of the attacks of other epidemics. So evident indeed was the influence of locality on disease, that Mr. Chadwick was able to show that, whilst the mean rate of mortality in a town would be represented as 1 in 42 annually of the whole population, in one district where an aggregate expenditure was requisite for executing the works, and so extensively would the suggested administrative organisation interfere with existing interests, and, as some might conceive, with local management and individual freedom of action. As the Board had power to provide for the execution of any legislative enactment without instituting still further and more formal inquiries. A Royal Commission, consisting of eminent members of both houses of parliament, civil engineers, and scientific men, was accordingly appointed, in 1844, to investigate the whole subject; and various questions connected with the public health. The evidence collected entirely corroborated that of the former commissions, of wretched wanderers and outcasts; Liverpool, with its 8000 damp cellars, and Manchester, with 50000 large houses opening directly into the street; Manchester, with whole quarters of narrow lanes and alleys, without any main sewer, unvisited by the scavenger, unprovided, almost impassable from mire, and reeking with filth and stench; the smaller towns, whether agricultural or manufacturing, with the want of necessary conveniences, were all insufficiently drained and ill supplied with water; all had their St. Gile's, their pestiferous lodging-houses, their fever-nests, their labourers' dwellings, where comfort and cleanliness were impracticable, and where pestilence and disease took the place of life.

In these statements the mass and in detail, it was impossible not to agree with the report that this was a state of things discrepant to the intelligence and civilization of the country, and that the removal of these evils was imperatively required. For, as Mr. Chadwick forcibly observed, it was incontestable, from the facts deduced, that "noxious physical agencies deprive the health and bodily condition of the population, and act as obstacles to education and to moral culture; that in abridging the duration of the adult life of the working classes, they check the growth of productive skill, and abridge the amount of social experience and steady moral habits in the community; that they substitute for a population that accumulates and produces, a destitute population that consumes and destroys; that a generation that is young, inexperienced, ignorant, credulous, irritable, passionate, and dangerous, having a perpetual tendency to moral as well as physical deterioration." And happily he was able to show, that the removal of these evils, by the necessary measures, not only might the more palpable and offensive evils be removed, but that it "is probable that the full insurable period of life indicated by the Swedish tables, that is, an increase of thirteen years at least, may be extended to the whole period of life." The remedial measures pointed out as of primary importance were the providing of a sufficient supply of good water to every house, an ample supply being at the same time furnished for the cleansing of the streets, for sewers, and for protection against fire; the enforcement of improved drainage by the adaptation of drains and public sewers, and the construction of water-closets in houses of every class; the preservation of the natural streams flowing near towns from the pollutions caused by the influx of the contents of the public sewers, and the employment of the sewage for agricultural purposes; the adoption of measures for securing a better class of labourers' dwellings; the licensing of common lodging-houses, and placing them under strict control of the Board of health, &c., and the appointment of district medical officers, "independent of private practice, and with the securities of special qualifications and responsibilities, to initiate sanitary measures and to carry them into effect." From estimates he was able to show that, whilst the expenses of executing these various improvements would in fact be a pecuniary saving, "by diminishing the existing charges attendant on sickness and premature mortality," those expenses might be met with facility by means of loans, on the security of the rates, the charge being spread over 30 years, during which the original outlay as well as the interest should be repaid, and thus be avoided "the oppression and injustice so repeatedly reviled for the whole immense tax laid on such works, upon persons who have only short interest in the benefit." These suggestions have since for the most part been embodied in the Health of Towns Act, and other sanitary measures passed by the Legislature. The subject of intra-mural interments was also considered by Mr. Chadwick in a special report in the following year.

But, searching as had been the investigation, and unde-
and the conclusions arrived at were in effect the same as those of Mr. Chadwick. In their Reports, dated June 1844 and February 1845, they made great questions bearing on the sanitary regulation of populous places — sewerage, drainage, paving, cleansing, removal of nuisances, consumption of smoke, supply of water, public baths, &c., &c. The most fatal to the metropolis, the unhappy Backwell cases, and streets, and interment in towns — and found, almost uni-
versally, all of them in an extremely unsatisfactory condition; and having examined the existing law with regard to those subjects, expressed their opinion that it would be necessary to make the laws of the metropolis more efficacious, before the improvements so much desired can be fully accomplished.”

Thus fortified, the ministers framed a bill embodying many of the provisions of their recommendations. The Bill was introduced into Parliament by the Right Hon. Lord Lincoln, Chief Commissioner of Woods and Forests; but it was explained that it was introduced mainly with a view that its provisions might be carefully considered during the recess, and no attempt was made to carry it further.

A change of ministry interfered with its progress in the next session. In 1847, however, Lord Morpeth, who had succeeded Lord Lincoln as Commissioner of Woods and Forests, introduced an amended bill, but though, in consequence, the Bill had the support of the cabinet, the ministry he consented to withdraw the clause which included the metropolis within its provisions, he failed to carry the meas-
ure that session. In the next session it was again brought forward, and the clause which limited the powers of the Board of Health to the metropolis (an omission in the 1846 Bill) was inserted. There was a special meeting of the House of Commons out of doors, and the Bill, with a few amendments, received the Royal Assent.

The object of the Public Health Act of 1848, as stated in its preamble, is to make “further and more effectual provisions for improving the sanitary condition of towns and populous places in England and Wales” [the metropolis being excepted from its operations]; for which purpose it is declared to be expedient that the supply of water to such towns and places, and the sewerage, drainage, cleansing and paving thereof, should, as far as practicable, be placed under one and the same local management and control, subject to the general supervision of a “General Board of Health,” consisting of the First Commissioner of Woods and Forests, for the time being, and two commissioners appointed by royal warrant, to whom the superintendence and execution of the Act are to be entrusted. The Act is of great length, containing no fewer than 153 clauses; but as it is an Act of the greatest possible importance, as forming the basis of subse-
quent sanitary improvement, it seems advisable to indicate briefly its leading provisions—as, for a similar reason, we have entered at some length into its history.

1. As to the application of the Act. It was in no case to be applied without a public preliminary inquiry, which the General Board had the power to order on the petition of one-tenth of the ratepayers of any such place as came within the cognisance of the Act, or where the average deaths for seven years should appear, from the Registrar-General’s Returns, to be above 20 in a thousand. In either of these cases a superintending inspector may be sent—14 days’ notice by advertisement, &c., having been given in such locality—to examine personally by witnesses into the sewerage, drainage, water supply, burial grounds, &c., and report thereon to the Board. If the General Board now deem it expedient to apply the Act, the Queen may, if there be no local act, by an Order in Council order the Act, or any part of it, to be applied, and in such case, if the application of the Act, the Privy Council may make a provisional order for its application, such provisional order to be afterwards sanctioned by parliament. In every such case the carrying out the prov-
isions of the Act is entrusted to the Local Board of Health created by it, who are to appoint a surveyor, an inspector of nuisances, and a medical officer, with other necessary officers. In a corporate town the members of the Corporation are to constitute the Local Board of Health, in other places the members of the local board of guardians. In each case the entire sanitary government is vested solely in the Local Board of Health.

2. As to the powers of the Local Board, it is imperative on them to provide for the supply of water, public baths, &c.; for the construction of public conveniences; and for house drainage by causing sufficient drains to be con-
structed in all new houses, or in any house which may be without a proper drain communicating with a main sewer; they may also cause due provision to be made as to privies, &c. The Board are to make rates for the purposes of the Act, the ratepayers to be assessed accordingly. The times proper cause a thorough surface cleansing and watering of all streets; provide for the storing and taking away of dust, &c.; and cause nuisances to be removed, and filthy and un-
healthy places to be purified and whitewashed. The Board may also provide a constant supply of pure water, for the purposes of the Act; but not construct new water-works if a Company is able and willing to pro-
vide a sufficient supply on reasonable terms; and in any case the consent of the local board has to be obtained, before contracting to purchase old, or to construct new water-works or gas-works. The office of surveyor of high-
vays is vested in the local board, who must see that the highways are properly formed and lighted; that new streets are formed, and that all new buildings are in accordance with the terms of the Acts of parliament.

3. The local boards may, subject to the control of the General Board, close any surcharged burial ground, and provide general cemeteries for persons of all religious denominations.

4. Subject to the control of the local boards, the General Board may levy taxes, and for the construction of any per-
manent work may—but only with the sanction of the General Board—borrow money, to be repaid with interest, by means of a special Act of parliament. Provision is made for appeal, in various cases, to the General Board, on the part of persons who regard as excessive the assessments or charges made upon them for private improve-
ments, and also against various orders of the board which may lie open to the appearance of being partial or oppressive to individuals.

The intention of the Act in respect of local management and central control has been, in short, to cast upon the inha-
bители of a town the duty of making provision for the public health, and of carrying out local improvements, by means of a local agency elected by, and responsible to, the rate-payers; while, in order to ensure the efficiency of the more costly and permanent works and their economic construction, the fit qualification of the sanitary officers, the security of indi-
viduals from local bias and oppression, and the assuring of future rate-payers from the burdens arising out of an un-
thriftily mortgaging of rates, a General Board is provided with a certain well-defined power of supervision and control. Mr. Chadwick, who, beside the Reports noticed above, had taken a leading part in inquiries embodied in two other reports on the water-supply and the drainage of towns—in the former of which he strenuously advocated the adoption of the con-
clusion of the report of the Select Committee of the House of Commons, that the lucid exposition of the advantages of drainage by glazed earthenware pipes—was one of the members of the General Board appointed under the new Act; and to his intimate acquaintance with the whole subject, and well-directed energy, its early success must mainly be attributed. Subse-
quent acts, continuing, and in certain minor points amending, the original Act, have been passed; and in 1854 one by which the General Board was re-constituted, under the pro-
visions of which the Board consists of a President, the principal Secretaries of State, and the President and Vice-
President of the Board of Trade.

There appears, however, a probability that the great principle of the Health of Towns Act, local agency combined with central control, is about to be abandoned; a bill having been introduced (April 2, 1858) by the present government, with the declared in-
tention to “decentralise the whole system.” It proposes to allow the General Board of Health to cease to exist, in the middle of 1858; and to enable the ratepayers of towns to constitute local boards, which, as well as the existing local boards, “shall have the amplest powers of self-administration, and shall no longer be subjected to the necessity of referring to the Central Board.” It is not improbable that it is to be aggrivated are to have a power of appeal to the Secret-
ary of State for the Home Department. In its present crude shape the bill is unlikely to become law, but as it is a concession to a popular delusion against the alleged “stairs” and “dangers” here in the Act, and its features, be adopted; and thus the accumulated experience and scientific informa-
tion of the officers of the General Board will be lost, and the
door opened wide for a return to the old apathy, mismanage-
ment and negligence, to local inefficiency, waste, peculation,
and favouritism. The "general medical functions of the
Board of Health" are to be dealt with in a separate measure,
"they being distinctly central and governmental functions."

Since the passing of the Health of Towns Act, applications
have been made by several hundred places for a 'preliminary
inquiry' into their sanitary condition by the inspectors of
the General Board. How much such an act was needed—
how little had been accomplished by mere local effort, not-
withstanding the "enormous modifications" introduced by
the Law Reform Act, the Sanitary Reports, the Reports of the
Royal Commission, the Returns of the Registrar-General,
and the teaching of cholera and fever—has been shown in the most convincing manner by these 'preliminary'
inquiries in recent applicants for the-passage of the Health of
Towns Act to the present day, and extending over almost every
district of England and Wales. We have selected from recent
reports of the superintending inspectors a few special instances as illustrating the present state of too
many 'towns and populous places,' not yet brought under
the cognizance of the Health of Towns Act, including
sea-side and inland watering-places and resorts of invalids;
mining and manufacturing towns and villages in the north
of England and of Wales; rural towns of the eastern, southern,
and western counties of England; but curiously, they, after all, but tell, with variations, the same sickening
story of wretched quarters—often in close, though scarce
suspected proximity with the open and airy dwellings of the
afflicted, dilapidated, loathsome from without, without the
commonest appliances for decency, with an insufficient
supply of water, and, what is to be obtained, hard and
impure; many of the streets where fever is never absent;
lodging-houses where men, women, and children are huddled
together, in a fever-thatched hell, dilapidated, loaded with
all their abominations, in the midst of the most densely
populated localities; burial grounds surcharged, and the
like—all seemingly continued in defiance of sanitary
principles the most obvious to the commonest understanding,
but, in truth, usually continued through sheer ignorance or
the part of the influential classes that such things exist, and
the absence of any responsible officer whose duty it is to
make himself acquainted with their existence and to apply
the remedy. The case, therefore, now moved also, reference to
our towns and populous places, where every one has been left
to do as he likes with himself and his own, to illustrate the
evil consequences of neglect of sanitary regulations. For
the miserable loss of health and life among our soldiers at Scutari
and in the Crimea, where—"as military authorities themselves
admit,—the arms of the enemy slew but few in comparison
with the ravages of disease, and the recent astounding disclo-
sures respecting our barracks at home, more than sufficiently
prove the necessity for constant and judicious watch-
fulness, and authoritative control. Happily, too, in the same
quarter we have a striking illustration of the benefit of
sanitary regulations. For, both in the hospitals of the
Borphorus and in the Crimean camp, twice, more than once, and
precautionary measures of the Sanitary Commissioners,
sent out from England in January 1855, been brought into
operation, than the number of deaths, and the amount and
violence of the sickness, were abated; and ultimately the
very remarkable fact was established, that notwithstanding
all the hardships, exposure, and fatigue attendant on a state
of warfare, the actual mortality was lower than in the bar-
racks in England—a fact which renders the more strange and
important, as the removal of which barracks should after-
wards have been suffered to continue.

Up to the end of 1857 about 250 places had been brought
under the operation of the Health of Towns Act. In a fair
proportion of those places sanitary works of an efficient
order have been executed. The sanitary works have,
moreover, been chiefly those of drainage and water supply,
and in both these matters some of the works have been on
a scale of considerable magnitude. By the earthworks pipe
drains, and their connections to the new water-courses, in
their place or peculiarity of site, the local boards have in most
instances been enabled to effect thorough drainage with com-
parative readiness and economy. The utilisation of the
sewage, however, has not, however, been brought into general
successful operation; and in a small number of cases it has
been made that the successful drainage of the town has resulted
in the pollution of the natural streams—a necessary con-
sequence of such works where the outfall is into the water
courses, and no sufficient measures are taken for the utilisa-
tion of the sewage, and the purification of the waste water.
The means adopted for obtaining and distributing an ample
supply of pure water have proved very generally satisfactory,
and now in numerous places where only a scanty supply of
water had heretofore been had, water of the purest quality
is abundantly provided with water of excellent quality. And
wherever these sanitary works have been judicially
planned and properly carried out, there has followed a marked
improvement in the general health and comfort, while the
sanitary reforms have been accompanied by a marked
increase in the birth rate, a decrease in the death rate, and a
fairly reduction in the rate of mortality. The usual
mean duration of life in the town has been lengthened. The
application of sanitary measures has not however been con-
fined to the towns under the Health of Towns Act. Several
practicably all the large manufacturing towns have benefited
by local acts. At Liverpool and Manchester, for instance, vast
and very costly works have been constructed for bringing to
those places a supply of pure water from a considerable
distance; and at Glasgow a similar supply has been obtained,
at a great expense, but apparently a permanent advantage.

We stated that the metropolis was exempted from the
operations of the Health of Towns Act. Several Acts were
indeed passed to meet particular evils, but notwithstanding
that the necessity for some sanitary supervision was ad-
mited on all hands, so strong was the feeling of the civic
corporation and the parish vestries against centralisation
of authority, that it was not until 1855 that a measure intended
to secure to London the same sanitary improvements as the
Health of Towns Act offered to the rest of the country came
law. The Metropolis Local Management Act is how-
ever a far longer and more cumbersome measure than the
former (it contains 261 clauses and several schedules), and its
machinery is larger and more complex; it must suffice there-
fore to say that its objects and scope are very similar, how-
ever different in some respects are its modes of operation.
The executive body created by it is entitled the 'Metropol-
itan Board of Works,' and consists of a president, with a
cabinet and departmental councils, to deal with the
vestries of the metropolitan parishes, and the common
council of the city. To this board was transferred the
powers of the former Commissioners of Sewers, the super-
vision of all metropolitan buildings, the laying out of new
creets, and the direction of the public works, including
the parks, &c. But within certain limits a controlling power was entrusted
to the Chief Commissioner of Works and Buildings. The
great work which was cast upon the new board was the
purification of the Thames, by the interception of the sewage
of London, which the board was ordered by parliament to
accomplish. In this it has however made little progress, not
having been able to satisfy the government (or the public) of
the sufficiency of its plans. In other great matters, as the
protection and regulation of the water supply and the
creation of those parks and grounds which were necessary
for enjoyment and recreation within those towns and
suburbs, &c., it has also been content to discuss and to plan.
In small matters its officers have found sufficient occupation.
But on the whole, as from its constitution might have
been anticipated, it has hitherto proved rather a board of discus-
sion than, as it was to have been, a board of executive
action. The Health of Towns Act, and special Acts similar to the
Metropolis Local Management Act, would probably well suit,
if properly carried out, for the sanitary regulations of the
villages and small towns, but it is not yet to be said that there
are many towns in which such acts have no force, general
measures have been, and still continue to be, required
to meet particular sanitary evils. We cannot enumerate all
of these, but it may be convenient to mention the chief
sanitary evils which have arisen from the urban
regulation of the establishment of baths and Washhouses, passed
in 1846, is noticed under another head, [Baths and Wash-
houses, S. 2]; and as the Towns Improvement Act of 1847,
which consolidates previous acts respecting paving, draining, cleansing, and improving towns, and contains many valuable new clauses, created new machinery for carrying its provisions into effect, and accomplished much less than its framers anticipated, we may pass at once to the measures passed subsequently, which too are to be regarded as in the same spirit. The Nuisances Removal Act (1848) was intended to effect with respect to the removal of nuisances, and the enforcement of regulations for the prevention or mitigation of epidemic, endemic, or contagious diseases, the same end in places not within the county borough of Towns as in such places would be accomplished under its powers. Like that Act this has been more than once amended. In 1849 the only sanitary enactment was an extension of the Metropolitan Acts.

In 1850 was passed an important Act to make better provision for the Interment of the Dead in and near the Metropolis. Recognising the great truth that all interment within the boundaries of a city is in opposition to sanitary principles, it provided that when the General Board of Health, who were appointed to carry into effect the provisions of the Act, should see fit, they might report to her Majesty that interment in any church, chapel, or burial ground, ought to be discontinued; whereas the Act directed that the powers of the corporation directing burial be wholly discontinued therein after a certain fixed period. The Act also empowered the General Board to purchase existing, or to form new cemeteries at convenient distances from the metropolis, and the construction of spacious and neat cemeteries on all sides, but at some distance from the metropolis, though the actual accomplishment of these objects has been, I believe, successfully carried into effect; a new State for Home Affairs. An Act was passed the following year amending the Burial Act of 1850, and extending its provisions to any city or town in England. Another enactment was passed in 1857. In 1856 was also passed an Act bearing on the health of young persons and females working in factories, by which, as amended in 1858, the period of labour of such persons was restricted to between the hours of six in the morning and six in the evening, or during winter from seven to seven, and on Saturday to eight to eight.

A much needed Act was passed in 1851 for the Well-ordering of Common Lodging Houses; and in the same session one for encouraging the establishment of such houses of the Metropolitan district of London. The Act was passed in 1850 but the measures were required, what has been already said will have sufficient to show; but as the power of entry and search is still by some regarded as oppressive, an instance or two, exhibiting in detail the true character of such places immediately before the passing of the first Act, from the reports of the superintending inspectors of the Board of Health, may not be superfluous. But we shall only give one or two instances; for such details though it is wise to shun one’s eyes to their reality, are too painful and humiliating to dwell on; and we select them not from the great centres of population, where their occurrence is more frequent, but from the borough of Southwark, where their existence might hardly be anticipated. In Bacup, Lancashire, Mr. Lee found the common lodging-houses "hot-beds of disease and vice. . . . Men, women and children, and frequently dogs, form a promiscuous herd, all sleeping in the same room, from which every breath of pure air is excluded. . . . Most of the lodgers sleep in a state of absolute nudity, and decency, with the greater portion of them, has long ceased to be thought of. . . . In one house he found, in a single week, nine illegitimate births, nine smallpox cases, and dog. . . ." In another he found in one room 7 beds, containing 7 females and 9 males. But bad as this seems it is purity itself in comparison with what has been found in other parts of the country. Thus at Cardiff Mr. Ratcliffe, in a recent visit to that town, gives plans of a street (Stanley-street), several of the houses in which are common lodging-houses. One, No. 17, is larger than most others in the same street. Like the rest it has but a single living room, which is 16 feet 10 inches long, 17 feet 5 inches deep, and 8 feet 11 inches high. This room the Superintendent of Police visited by Mr. Rammell’s desire. On the first visit he found in it "54 persons, men, women, and children; they live, eat, and sleep all in this one room." He visited it again the following day, and found it only more crowded, but many more came in to sleep at nights. . . . There are no bedsteads, but all the lodgers lie on the ground or floor. . . . Each party had with them all their stock, consisting of heaps of rags, bones, salt-fish, rotten potatoes, and such things. The stench was hardly endurable. "This living room opened into a small outer court, in one corner of which was an open privy. On a third visit, seven days later, he found on the floor of the crowded room a woman who had been confined there during two days, on which occasion the privy had been closed; and these did not need "well-ordering", even at the risk of some little infringement on the owner’s right over his castle. The "well-ordering" Act has everywhere operated good; and as far as it has been realised the other has been extremely beneficial. The Smithfield Market Removal Act of 1851; and the Metropolitan Water Supply Act of 1852 (by which the water companies taking their supply from the Thames are, with the exception of the Chelsea Company, prohibited from taking any water from the Thames, or from any streams flowing from it or its tributary streams below Teddington lock), are sufficiently referred to in the following article. [PUBLIC IMPROVEMENTS. S. 2.]

In 1855 was passed an Act which, as amended by the Act of 1857, renders it compulsory to have all furnaces employed for manufacturing purposes within the limits of the metropolis, and the furnaces of all steam-boats plying on the Thames, so constructed or altered as to consume their own smoke, a measure which has had the effect of greatly improving the London atmosphere. In the same year the legislature rendered the practice of vaccination compulsory.

In 1854 was enacted the Board of Health Reconstitution Act, and among other provisions, the Metropolitan Burials Act, and the Metropolitan Sewers Act, which have been already referred to. In 1855 were passed—extremely useful Act for the Inspection of Coal Mines, which may be expected eventually to effect important sanitary improvements in such places; an Act for the Better Prevention of Diseases, which gives the General Board of Health additional and stringent powers in case of the recurrence of any formidable epidemic, endemic, or contagious disease; an Act for the amendment and consolidation of previous Nuisances Removal and Disposal of Offences Acts; an Act repealing all previous acts and more strictly defining the powers of the various bodies appointed to enforce its provisions; an Act to amend the Laws relating to the construction of Metropolis and its Neighbourhood; and an Act for Facilitating the erection of Dwelling-houses for the Labouring Classes. Subsequent acts of a sanitary character have been chiefly emendatory.

Our review has been confined to England and Wales, and it is there that the greatest progress has undoubtedly been made. But in Scotland, by the very important ‘Act to make more effectual provision for regulating the police of towns and populous places in Scotland, and for paving, draining, cleansing, lighting, and improving the same’ (1830); the Burial Grounds Act (abolishing the system to that of England), and the Act to Facilitate the Erection of Dwelling-houses for the Working Classes (1855); and the Smoke Nuisance Abatement Act of 1857; and in Ireland by the towns Improvement Act of 1850, the Act for providing of Improved Dwelling-houses for the Labouring Classes (known as the Cotter Tenant’s Act), and the Burial Grounds Act (similar to the English Act) of 1856, very much has been done towards placing those portions of the empire on a level with England in reference to its sanitary provisions. Much doubtless remains to be accomplished in and for our populous places—indeed sanitary improvement can but be regarded as in its early stage of progress—but it is still possible that what has been accomplished within the last few years without thankfulness, or forward without hope. All that we have said has had reference to ‘towns and populous places,’ and it is in them that sanitary law has first need to be enforced. The average excess of mortality in town districts is at least 8 in the thousand over that of the country districts of England. Yet even in country districts, as was well observed by the
Registrar-General in one of his valuable reports (1868), "there is room for immense improvements in the sanitary condition of the population." And we cannot perhaps better conclude a paper on the Public Health, in which the sanitary state of the town population has been almost in-
clusively dwelt on, than by quoting what he—speaking with the authority derived from a knowledge unrivalled in extent and accuracy of the sanitary state of the whole of England and Wales—asserted of his belief that the mortality of London is still high, if we look at it from the present time to that in Europe,—saying "the sanitary condition of the rural districts:—
"The germ of insolvency are scattered about in every village; for the rational laws of health are violated alike in the sparsely inhabited districts of the county and in the close-housed and destitute districts of the town. Sometimes rest on damp undrained ground; they lie often at the bottom of pit-like depressions of the earth, instead of standing on the sides of the higher grounds, from which the water flows away naturally, and the decaying organiza-
tions are dispersed and decomposed by the winds. The farming house is often close to the farmyard, on a low part of the farm, and is surrounded by buildings, ricks, and trees. In the yard, or near it, the refuse of the house, and of all the animal and vegetable productions of the farm; butchers and giving off noxious vapours. Into the pond, out of which the cattle drink, the ammoniacal liquor falls that should find its way over the land. And it happens that if the air is stagnant for some days, if the temperature is high, if some sickly or diseased animals are near at hand, or if the land is surrounded by salubrious fields, the field becomes a scene of suffering, the cattle perish by pleuro-neumonias, the animals are attacked by scarlatina, the wife has low fever, or the farmer himself dies. It is impossible to tell where the name, enrolled in the register of deaths. About 6,400 English farmers die in a year, and of them many are young; 2,600 are under 65 years of age. In the dairy, a little dirt spoils the milk, butter, or cheese; unless the vessels of the brewery are clean the ale is injured and harmless; and farmers have hence learned by experience the importance of cleanliness in the interior of their houses. From the taste for household cleanliness has been diffused throughout the surrounding population. They have only to order the air which they breathe about their homes in better order, and cleanliness will follow them, the habit of being clean is spreading to the people in the world. To place any of the new farmhouses and cottages to be built on certain elevations is the first point; to carry out and to cover with earth all the refuse of the house and yards daily will prevent the escape of the ammonia, the most precious part of the manure, and at the same time rid the atmosphere of the fatal malarial that surrounds the farmhouses and cottages of the country.—These matters well deserve the attention of English landed proprietors, who largely employ these sanitary matters than their agents, and can at once give effect to improvements beyond the reach of the small proprietors of other countries."

IMPROVEMENTS. The present article is intended to indicate broadly the progress of architectural and other public works of an important character in the metropolis since the publication of the "Penny Cyclopedia," and, though with less particularity, similar progress in provincial towns.

Since that date London has been greatly altered. If there have been no such rapid or extraordinary architectural trans-
formations as in Paris, there has been continuous and steady improvement. New streets have been opened, and obstruc-
tions have been removed. Some streets which are now so-called "villas," have been added to the suburbs on nearly every side. New parks and public places have been formed. The drainage of the vast area which is now included within the metropolitan boundaries, has come to be regarded as a question of general concern, and the plans which the system has been greatly improved, a scheme of metropolitan drainage, of a magnitude unrivalled in the capitals of ancient or modern Europe, by which the entire sewage of London and the suburbs will be carried some miles below the metro-
politan limits before it is discharged into the Thames, only seems to wait for its adoption by the government a decision as to certain subsidiary points on which the representative of the government and the representatives of the London peaceable and extensive plans. London is no longer an open city. Its water has been declared illegal, and numerous convenient conveniences, some of them of great extent, have been formed at a due distance from the City. The water-supply has been in-
cressed and purified; and many other sanitary reforms have been accomplished. New museums and other educational institutions of a national character have been established. A vast legislative palace has been reared; a new Royal Ex-
change, numerous churches and chapels, and many other public buildings of considerable size and costliness, as well as many great commercial works, have been constructed; and street architecture has assumed an entirely new char-
acter and consequence. And in all these matters the larger provinces have continued to compete with the metropolis.

New Streets. The new streets in the metropolis have added much to the public convenience, and greatly improved the appearance of certain quarters; but much more might have been easily accomplished had the improvement been carried out as part of a well-considered general plan, instead of being disconnected and local expedients. In the City, however, something like a general plan has been observed. The erection of the new London Bridge led to the formation of a new and important street—Shad Thames. This was due to the necessity of still greater changes; and the civic authorities have since kept that necessity steadily in view. The erec-
tion of the new Royal Exchange afforded an opportunity for opening the area surrounding that building. By the removal of the houses and the streets which were on the north side of St. Paul's, an excellent street—New Cannon Street—has been formed from King William Street to the east side of St. Paul's Churchyard. This street has been for the most part carried through by the Corporation of the City of London; and the name, "New Cannon Street," is a consider-
able architectural pretension: it is greatly to be hoped that the corporation will not allow the fine view of St. Paul's Cathedral opened by New Cannon Street to be obstructed by the erection of a building on the triangular space at present left unoccupied by the present form of the new street. To render New Cannon Street as serviceable for traffic as from its width and position it ought to be, it will be necessary to make very extensive alterations in the area surrounding St. Paul's Cathedral—and such alterations are equally desirable for the appearance and other effects of the City. Another, though less important new line of thoroughfare, is Gresham Street, extending from Lothbury to the Post Office. More recently a wide street has been formed as a continuation northward of Farrington Street. It is called Victoria Street, and extends from the foot of Holborn Hill to Clerkenwell Workhouse. It passes through a very poor neighbourhood, and as yet no buildings have been erected along it.

Beyond the limits of the 'City,' the first place among the new lines of thoroughfare and the most completely formed is that which connects Holborn with Oxford Street by a straight and wide road, which passes to the north of the old mean and circuitous way by St. Giles's Church. On the north side of New Oxford Street a few good houses have been built, but much less has been done for the aspect of the street than could have been wished. In the same vicinity Endell Street has opened a way from Long Acre to Bloomsbury, and thus formed a tolerably broad though somewhat awkward and indirect thoroughfare from the Strand by Waterloo Bridge to New Oxford Street and Tottenham Court Road. Cranbourn Street at the west end of Long Acre and New Coventry Street, between Leicester Square and Coventry Street, have in like manner been opened, and the thoroughfare has also been extended, but further improvement is still greatly needed in that quarter. At Westminster a fine line of road has been formed from the Abbey to Pimlico, but the greater part of it remains uncovered with buildings; at present only a few blocks are solid, and a portion of it is on the bank of the river; but the remainder is only a narrow strip, and the buildings are mostly composed of the large mass of houses about Buckingham Gate which formed so great an obstruction to the road-way, and so un-
sightly an appendage to the royal abode, the grounds of which have thus been somewhat extended; and at Chelsea by the large building which now forms the south-west corner of the streets as approaches to the new suspension bridge. At the east-end of London the most important new line of street is one called Commercial Street, extending from Whitechapel.
Commissions who had been appointed to adjudicate, decided in favour of a design by Mr. Charles Barry, R.A., then best known as the architect of the Travellers' and Reform Club-Houses. After much discussion he was instructed to carry out his design. The first portion of the works undertaken was the river wall, which was constructed by means of a coffer dam, under the joint superintendence and direction of the engineer and civil engineer. On the completion of the river wall, the foundations of the building having been simultaneously proceeded with, the first stone of the building was laid, without any ceremony, by the architect's wife, April 7th, 1840. From this time buildings, under the direction of Mr. E. M. Barry, (in a paper descriptive of the new palace, read before the Royal Institute of British Architects, Feb. 1, 1856, and of which, as it may be regarded as semi-official, I have made use,) have much altered and modified the portions of the edifices have been completed, and at this moment little remains to be done. The Speaker's House is all but finished, and will be occupied after Easter. The residence in the south wing will be completed in a few months, and before long the house, the royal staircase and the staircases will be ready for occupation, so that by the close of the year the present works at the new palace will be brought to a close. Much has been said," continues Mr. Barry, "and I will not attempt to construct..." but when the difficulties of all kinds which have been experienced are duly considered, and it is borne in mind that the public business of the country has never been interrupted for an hour, but has always possessed temporary accommodation on the site, which has only been handed over piecemeal to the builders—architects, at any rate, will not think the time that has elapsed between the laying of the first stone in 1840, and the completion of the building in 1858, has not something to show in the work that has been done." In this statement, as we quote it from Mr. Barry's work, there may be, as the time has been spent on the building, the extent, character, and complexity of the works, even had there been no extraneous hindrances, would not have been sufficient to make it necessary for him to say that no other building at all approaching it in size, solidly of construction, and richness of external ornamentation, has ever been erected in anything like so short a time.

The style of architecture adopted for the new palace is that commonly known as the perpendicular Gothic of the reign of Henry VII, but that style is chiefly known from the ecclesiastical and collegiate buildings erected in or about the reign of that monarch, whereas the architect himself says of the new palace, "it has been my aim to avoid the ecclesiastical, collegiate, casbah, and domestic styles, and to select that which I consider better suited to the peculiar appropriation of the buildings." The east, or river front, which stretches along the Thames a length of upwards of 1,000 feet, and contains the libraries and committee rooms, was the first portion of the exterior completed. Of this façade the central portion is a story higher than the rest, and two towers with high roofs flank each extremity. Except that the end towers project somewhat, the river front is not only uniform in height but uninterrupted. The arcades and parts, "reliance being placed," says Mr. Barry, "on breaking up the sky-line to avoid monstrosity." Throughout this front, as indeed with scarcely an exception throughout the building, the wall-surfaces are ornamented with arcades enriched with carving. "The carving between the stories of the river front was intended as a record in stone of English history. There are thirty-five bays exclusive of the two oriel bays; each of these thirty-five bays contains the arms of an English sovereign, beginning with Wranham I. and ending with William IV. The oriel bays bear the present Royal

4 A 2
Arms of England, with the motto, "Victoria Regina feliciter regnum.">" Examined closely the effect is extremely rich, though somewhat monotonous; but the enrichment is almost entirely lost when the façade is looked at from a sufficient distance to be viewed as a whole, and this is almost necessarily the effect produced by the light and shadow, or by the play of light and shadow. It is impossible not to regret that, by the adoption of bold breaks in the outline, a more picturesque combination has not been preserved to the reader.

The western front is much more varied, and promises to be much more satisfactory. But for its full effect it must wait for the removal of the present most unsightly law-courts, and the completion of the architect's design by the erection of a grand central tower with flanking turrets at the corner of Palace Yard. The great feature of this front is the Victoria Tower, which occupies the south-western extremity of the building. This magnificent structure is 70 feet square, and rises to an altitude of 546 feet to the top of the turrets, being the loftiest tower in existence.

It forms the royal entrance to the palace, the basement being a noble arch 60 feet high and 32 feet wide, under which the royal carriage passes. Triple windows of very rich and beautiful design occupy the chief wall-space of the two principal stories. The entire unpierced wall-surface of this vast tower is covered with paneling, with canopied niches containing statues of the monarchs of England, and with the arms and supporters of the different sovereigns. A pierced balcony runs the width of the tower, from the angles to a height of 85 feet above the cornice. From the summit of the roof will float on state occasions the royal standard; and the scale on which the whole is contemplated from the top of the tower will be "of rolled sheet iron firmly bolted together, 110 feet long, 3 feet in diameter at the base, and weighing between 16 and 18 tons," while the flag, which will be 60 feet long and 40 feet wide, will have to be hoisted to its place by machinery. The Victoria Tower may safely be said to be the finest tower of medieval date for beauty and grandeur as well as for mere size. Two other towers form equally interesting features in the design—the Central Tower, less than the Victoria Tower, crowned by a round tower with a light and elegant spire, which rises to a height of upwards of 300 feet, in many points of view grouping admirably with the main features of the palace; and the Clock Tower at the north-western angle, by Bridge-street, which though little lower than the Victoria Tower, is much less ornate, it being the architect's object "in designing this tower to make the clock the predominant feature: all else was to be pedestal or roof.

In the interior, the chief interest of course centres on the 'Houses of Parliament.' These are placed pretty nearly in the midst of the building. In the very centre is the Central Hall, a noble octagonal chamber covered by a stone groined roof 70 feet in span, which forms the principal floor of the Central Tower. The central hall is covered by an arched gallery on four sides, south lead to the House of Peers, and a similar corridor and lobby on the north to the House of Commons. The House of Peers, as the chamber in which the sovereign delivers the royal speech in the presence of the members of both houses of parliament, as well as members of the diplomatic corps and of the royal household, is the larger and more splendidly fitted apartment. But knowing its purpose, the first emotion of the stranger is usually surprise at its appearance. The room is about 250 feet long, 32 feet broad, and height 45 feet. It has six windows, filled with stained glass, on the east, and the same number on the west side, and three compartments corresponding to them in shape, but filled with pan-tiles in fresco, at the south, or throne end, and the similarly shaped and gilt decorations at the north, or bar end. The ceiling is flat, and divided by longitudinal and transverse beams into 18 compartments, which are subdivided into panels, and these, as well as the wall panelling, are painted and gilded, the letters of the wall-surface which is not occupied by carved wood or stucco, is decorated with gilding or colour; and in respect of its decoration the room is probably the most elaborate and gaudy of all the apartments in the House, since the decline of medieval architecture. The House of Commons is 250 feet long, 45 feet broad, and 44 feet to the centre of the present ceiling, the original ceiling being concealed by one of a different form, with a view to remedy certain acoustic defects. In character this apartment bears a general resem-

...
as it does an area of upwards of eight acres, and comprising eleven hundred apartments, above a hundred staircases (some of them of grand proportions), and more than two miles of corridors and passages; while as a spokesman of his active and lucrative position, to one who had a title to be regarded as the architect and to the country. We have spoken freely of what we regard as its defects as a work of art, but we gladly record our conviction that, with all its defects, it is by far the most satisfactory building which has during the present or the last century been erected in England, and we believe it to be the finest which during the same period has been erected in any part of Europe.

A year or two back it appeared likely that another building of the same kind would be undertaken in connexion with the new palace, and whereby some of the edifices, the government having in 1866 offered premiums to the amount of 5000L. to the architects of all nations, without re-tracting them as to style or cost, for a block of buildings which should embody the best scheme for the concentration of the principal Government Offices, on a site lying between Whitehall and the New Palace at Westminster; and also designs for two buildings which her Majesty’s Government have determined to erect forthwith, as parts of such general scheme,—on for the department of the Secretary of State for Foreign Affairs, the other for the Secretary of State for War." By the specified time 216 designs, embracing nearly 2000 drawings, were sent in, and 17 of them, by French and German as well as by British architects, were exhibited. The answer to the block-plans proposed the most extensive, and in fact impracticable, re-arrangements of the site; the designs extremely magnificent but quite practicable buildings. On all hands it was allowed that the most successful and the most necessary and best has displayed a very unusual amount of professional knowledge, taste, and power; and that the competition was by far the most successful of any of recent years. In the House of Commons, however, there appeared a very natural declination to provide funds for such a scheme, and could not be a scheme, and without any public intimidation, the Lords of the Treasury have cast aside the designs which they had induced the profession to prepare on the implied understanding that the work should be given to the successful competitor. But, in the House of Commons, Sir Benjamin Hall as commissioner of public buildings, directed a non-competing architect to design a new War Office on a more limited scale. Happily the transaction has been made public before the works have been actually commenced, and it is hardly conceivable that so flagrant a breach of faith can be justified, in now that its real character is understood. We therefore still have hope that whatever be the size and character of the buildings decided on, it will be referred to the premised competition, and if the public interest require it, then the execution unless they be found unsuitable.

Next to the new palace at Westminster, the most important recent architectural work is the British Museum, of which the architect was Sir A. W. N. Pugin. But it is in the article Lowson was written: and the portico was completed in April 1847; it was not however opened throughout till 1851. The building itself is the largest and most imposing example in the metropolis of the Grecian Ionic order, and the exterior has a certain monumental grandeur of character not inapropriate to its purpose. The interior few have been found to admire, either aesthetically or for its adaptation to the object for which it was designed. Even before it was completed it was found to be too small to accommodate the important collections in view for its purpose. As early as March, 1837, in an article on ‘The New Buildings at the British Museum,’ which appeared in the ‘Mechanics Magazine,’ vol. xxvi. p. 45, the question how best to obtain more room than the new buildings would afford, was discussed, and it was pointed out that ‘the space thus unfortunately wasted [by the great inner quadrangle] would have provided accommodation for the whole library, much superior to what is now proposed to afford it. A reading-room is established on each floor of the library, and is central, and is bounded on all four sides by galleries for the books, communicating with each other, and lighted from the top:’ and the writer, Mr. Thomas Watts (now one of the superior officers of the Museum), goes on to say: ‘but it was decided in due course by which arrangements which this arrangement pos-

sees over Sir Robert Smirke’s arrangements for the library and reading-room in the new building. But as so much care and money had been expended on the architectural features of the great quadrangle that it might seem barbarous to propose filling up the space,’ Mr. Watts suggests as another, and perhaps more practicable plan, for obtaining the requisite additional room, to remove one side of Montague Street and Montague Place, in order to make an extension of the building on the eastern and northern sides, to be executed ‘as occasion shall arise.’ This latter plan is the same in principle as that officially proposed to the Treasury on the part of the Museum Trustees in March 1853, but the rejection of the plan by the Government Commons for 1853 (except that Mr. Watts proposed to afford accommodation to the chief learned societies, on condition of their collections being opened to the Museum visitors) as the former is in principle the plan which was proposed on one occasion by the rejection of the plan in 1837, and was revived in 1853, and finally abandoned in the new Reading Room. Some years later Mr. Hawkins of the antique department in the British Museum proposed to erect a Board-room for the trustees, with studies for the chiefs of the libraries, offices for clerks, 

&c., in the centre of the quadrangle, connecting them by corridors with the galleries of the building itself. Mr. Hosking, the first professional architect who appears to have taken up the subject—laid before the Commission of Inquiry into the constitution of the British Museum in 1848, and before the Museum Trustees in November 1849, a plan for erecting within the quadrangle a modified or somewhat reduced copy of the Pantheon at Rome, or in other words a cupola-covered mand, 150 feet in diameter, and 100 feet high, ‘to form a grand central hall’ within the quadrangle, containing some important works of sculpture, and of such other objects proper to the purposes of the museum as most require that steady and equable light which is so well obtained from the eye of the cupola. The whole plan of this magnificent project did not meet the approval of the Trustees. In 1849 Mr. Fergusson published a plan of a building within the quadrangle to be used as a reading room and for library purposes; and in 1853 Sir Charles Barry, by direction of the government, designed very much on the same plan the British Museum buildings, the chief feature of his design being a grand central ball within the inner quadrangle: but neither the voluntary, nor the commanding design was destined to be carried into effect. In 1848 a new principal librarian, then keeper of printed books at the British Museum, was pressed on the trustees the necessity for providing additional room for the library, and laid before them a plan for obtaining a reading room and space for a large number of additional book-shelves within the quadrangle. In 1850 he produced such a more elaborate scheme, and this on the recommendation of the trustees, the government sanctioned. His plan, as put into working form by Mr. Sydney Smirke, was to erect within the inner quadrangle of the museum a Reading Room, circular in plan, and in the centre of a pyramidal cupola, to be covered with lead, and to afford for a large portion, if not the whole, of the printed books in galleries surrounding this great central apartment. This building, of which Mr. Sydney Smirke was the architect, was completed and opened for public use in May 1857. It is constructed principally of iron,—the supports being cast-iron piers, which carry girders of wrought iron strongly tied together, and these bear the dome. Between the main rite are brick arches, but the frame-work is of iron, and hence an immense saving of space is effected. The Reading Room is 140 feet in diameter, and 106 feet high: exceeding therefore in diameter every other dome in Europe, except that of the Pantheon at Rome, which is 143 feet in diameter. But it differs from the Pantheon greatly in its method of being lighted, the several openings being fitted with coloured glass, which, with the artificial lighting, the Pantheon being entirely lighted by a circular opening at the top 88 feet in diameter, while the Reading Room has a similar light at the top 40 feet across, and 30 large windows in the base of the dome. Little is seen of the interior, but the interior proportions and general effect are very pleasing, and it answers the purpose for which it was erected admirably. It affords ample accommodation for 300 readers, for whose comfort and convenience abundant provision is made, and space is reserved for the accommodation of 80,000 volumes: in the connected galleries and passages there is shelf-room for above a million volumes: and the whole arrangements afford an example of ingenious contrivance, as the buildings of the British Museum, by a new façade designed by Mr. Blore. In magnitude it is however greatly inferior to Nash’s façade, bad as that was in
most respects. The new front merely suggests the idea of a ‘terrace’ of a rather superior class of private residences: and the original poverty of character has been increased owing to the circumstance that the stone selected was of such friable quality that it called for a great deal of care to cover it with paint. The Marble Arch too, which, however incongruous with the palace, assisted in imparting to it a certain dignity of appearance, has been removed; and now forms the front entrance to Hyde Park.

The Treasury Buildings, Whitehall, have likewise undergone transformation. By some strange misconception the original building, erected in 1833, was so set out by the architect (Sir John Soane) that it could not be completed according to his design, and accordingly not according to Soane’s specifications. About 1845 Mr. Barry received directions to complete it according to a design he had prepared. Soane’s façade was consequently made to give place to one of a much more florid character, which with one of the three, and which is a rich and elegant example of Italianised Corinthian. Chamber’s Somerset House has been as far as possible completed by the erection of a west wing—the construction of a correspondent east wing being rendered impracticable by the erection of King’s College. The west wing of Somerset House has been built in a manner in every respect satisfactory: the architect was Mr. Pinnenthorpe. The same architect has also erected several other buildings for the government. One of the most pleasing of these is the Museum of Practical Geology, Jermyn Street, Piccadilly, which, for its position, its style, and its being, for some occult reason, turned towards the leading thoroughfare, the front towards the narrow bye-street. The building is a neat example of the Venetian palatial style; and the inner court is laid out with great taste, but the exhibition part of the edifice is not remarkably effective or convenient. Mr. Pinnenthorpe is also the architect of the fragment of the General Record Repository, Fetter Lane; of the additions made to the Ordnance Office in Pall Mall; and of the extensive range of offices for the Duchy of Cornwall, erected (1857) in Pimlico. The only other government building which requires notice, and that rather from its extent and massiveness than from its architectural merits—for it is the house of builder’s castellated—is the new building at the Tower.

Of civic buildings the chief is the new Royal Exchange by Mr. William Tite. The old exchange was destroyed by fire on the 10th of January, 1838, but the first stone of the new building was not laid till the 17th of January, 1843; it was opened by the Queen in person on the 28th of October, 1844. As in the old exchange there is an open central area appropriated to merchants (110 feet by 53) which is surrounded by small arcades, and there is a spacious corridor or merchants’ walk. The eastern end is chiefly occupied by banks; and near the centre of the building are some fine apartments—one being 100 feet long and another 80 feet by 40. The principal feature of the exterior is a Corinthian portico, at the west end, of eight columns with two intermediate. The Corinthian portico is 17 feet wide, and the diameter of the columns being 4 feet, their height 41 feet; and the pediment is filled with sculpture by Mr. Westmacott. The other parts of the building display considerable picturesque ness of character, but the southern side has been a good deal marred by the vandalism of the authorities, who have caused the granite pilers to be cut away in order to give a little more room to the windows of the shops with which, from motives of economy, the architect had not provided his plans. No notice of this or any other portion of the building may be noticed here, the Coal Exchange by Mr. Bunning, which was opened with some ceremony by Prince Albert in 1849. Architecturally however it is rather peculiar than beautiful, but it is said to be well arranged; both the Royal Exchange and the Coal Exchange were somewhat freely decorated with arabesques and other designs in fresco by Mr. Sang, but in both the painting has failed to withstand the test of the civic atmosphere.

But the year 1845 was not the general revival of Gothic church architecture. Churches were going up with surprising celerity everywhere beyond the limits of the city proper, but with greatest profuseness in the outskirts. Most of the new churches have occasion to refer to in the article London were Greek or Roman Catholic. Very few new churches belong to the Establishment as a matter of course Gothic, but almost invariably every dissenting place of worship and every Roman Catholic chapel is also in strict conformity with the period’s of pointed architecture. That this has been a great gain cannot well be doubted. Instead of grim caricatures of temples of Jupiter or Venus, or at best Minerva, we have fanes which can only suggest associations of Christian worship—though it may not at first present some. Such an architectural idea seems to serve to diversify the general monotony of our streets, and by their towers and spires to break the formality of what architectures call the ‘sky line.’ But hitherto there has been, as was the case with the so-called Greek churches, by far too many instances of the want of accurate judgment in the attempts to meet mediæval Gothic architects—forced thero probably in many instances by their clerical employers—have sought chiefly to produce a building which should faithfully accord in general form, as well as in the window-tracery, carvings, and other decorative parts, with the familiar saltires and crosses of the ‘Decorated,’ or ‘Perpendicular’ period; and it is not too much to say, with very little regard to the actual forms of worship and requirements of a church whose peculiar system of prayer and preaching was modelling after the lapse of those styles of architecture had not merely ceased to exist as a vigorous living reality, but had perished with the season and the order of things to which it belonged. The merit of the majority of recent churches lies there-fore in their picturesque ness of external form, and in the best of them, in the sober ‘religious’ splendour and impressiveness of their interior. There is abroad however a longing for a more perfect adaptation of ecclesiastical buildings to their actual use, a more thorough application of the discoveries of modern architecture and of a true and generous sense of the growing desire to cast off the merely servile adherence to mediæval precedent: the return, in a word, to the medieval spirit—to earnestness and truth of purpose, and freedom of design in the treatment of the building itself, and to the plainness and we believe will lead to a still greater advance; and if it fail to create for this nineteenth century an architectural character of its own, it will at any rate save it from the condemnation of being purely mimetic. So numerous are the recent London churches that it is difficult to misstate the innumerable, were it even desirable, to particularise them, and it will be sufficient, in order to avoid invidious distinctions, to refer as characteristic examples to the church of St. Stephen, New Church, the church of St. Matthew Sun Street, the expense of Miss Burdett Coutts, to that at Highbury, by Mr. Alom, which is noteworthy for its effective, though not costly interior; and to the very remarkable one of red and black brick by Mr. Butterfield, in Margaret Street, Langham Place, which will when finished be the most perfect illustration in London or its vicinity of the views and anticipations of the ecclesiologists; to Pugin’s Roman Catholic cathedral of St. George, Southwark; to the cathedral of the Catholic and Apostolic church, Gordon-square; to that at Amsterdam by Mr. Binneman; and to that at Deans, St. John’s Wood; and to the Baptist Chapel, Bloomsbury.

Of recently erected places of public entertainment, the principal is the new Opera House, Covent Garden. Covent Garden in order to make the gesture of a great increase in the various reversed of fortune was finally abandoned by the English drama, and in 1846 the interior was entirely remodelled by Mr. Albano, to adapt it to the service of the Italian opera. But it met with the usual fate of theatres, being destroyed by fire March 6, 1858. For a time it seemed probable that it would not be rebuilt, but the obstacles were ultimately removed, and a new theatre is rapidly advancing towards completion, which has been designed by Mr. Barry with all the requirements of the opera, but with various novel arrangements, which are intended to render it easily available for the regular drama, or for concerts, public meetings, &c. In size the new theatre is about one-fifth larger than its predecessor, being 240 feet long, 133 feet wide, and nearly 100 feet high, which is nearly equal to the dimensions of La Scala at Milan, the largest theatre in Europe. The proscenium is to be 60 feet by 40; the stage will be 90 feet and 60 deep, and 90 feet high, which is nearly equal to a semicircle instead of a square, the latter in size will be 75 feet deep, 65 feet broad, and 80 feet high; and there will be only three tiers of boxes. (The proportions of the old building will be found under Covent Garden). The new theatre has been much more freely used than in any former building of a similar kind. The roof formed of nine immense wrought iron lattice girders, each 90 feet long, 1 foot 6 inches thick, and 9 feet 6 inches deep, and weighing 18,000. The chief feature of the exterior—about which we regret to
see a great deal too muchшимy 'compo' ornament—is a Hexastyle Corinthian portico, 68 feet wide, and 80 feet high; the columns being 3 feet 8 inches in diameter, and 37 feet high. Flaxman's basii-relici, which were saved at the fire of the old theatre, have a place in the new portico, and his statues of tragedy and comedy are in niches on either side of it. The basement or lower story of the portico is intended to serve as a carriage porch, while the principal story will serve as a promenade, the entrance to it being from the adjacent houses. The upper story was opened in May 1858. A kind of conservatory or "floral arcade," of glass and iron, 340 feet long, 60 feet wide, and 60 feet high, is proposed to be built alongside of it, to be employed as a market for choice flowers by day, and as a conservatory for fruit for hothouses.

The increasing passion for music has also led to the erection of three or four large music halls—to say nothing of as many 'music and supper halls' for a less refined auditory, but which in size and style of decoration would a few years back have excited no little admiration if constructed for more aristocratic circles. The first of the former kind, St. Martin's Hall, Long Acre, built primarily for the use of Mr. Hullah's music classes, was first opened in 1850, but only fully completed in 1855. The hall is 100 feet long, 42 feet wide, and 42 feet high; and the smaller supper halls beneath. The architect was Mr. Westmacott. In form and general appearance it has been modelled on the old baronial hall, but though a handsome and well proportioned room, it wears too sombre a character for the interior, and is not so spectable, though far from perfect, and the floor being level, and the stage low, only those of the audience who have front seats can see the singers; moreover, it has the usual lack of sufficient, safe, and ready outlets. The exterior makes no attempt of sound monumentality in part, as it is

has no claim to originality, and the absence of a similar building, in a place of such importance, is a source of regret. The Excise Office, in Broad Street, built by James Gandon in 1768, of which it was remarked in the article London 'Penny Cyclopaedia,' vol. vi. p. 114, "its size is almost as great as the grandeur of mass, and greatness of manner, combined with simplicity, it surpasses everything else in the metropolis." Unfortunately on the removal of the Excise department no other use was made of it, and it was destroyed by fire in 1871. For a building, the chief merit of which is its size, there is a greater number of separate offices than any other in the kingdom.

Another class of city buildings which has done much to raise the character of London are the club-houses, which includes the banking-houses and insurance-offices. To many Paxman's, Parnell and Smith, who have taken for their type the Palazzo Carlo, of the great Venetian, or rather Florentine, architect, have been so original that has been placed on the shady-side of Pall-Mall. Nearly opposite to it is another club-houses copied from Sansovino: the Army and Navy, by Messrs. Nelson and Innes in the Junior United Service Club, Regent Street, a spacious and very stately pile, which replaces a smaller and less assuming one by Sir Robert Smirke.

A few private residences have been built at the west-end during the last few years which may help to maintain the prestige due to the abodes of our nobles and wealthy commouners, somewhat endangered by the palatial splendour of the club-houses. Of these the first and grandest is Bridge-water House, Cleveland Bow, built by Sir Charles Barry, 1845-50, for the late Earl of Eddesmere. In its general character, and in the gracefulness and finish of its details, it reminds the observer of the designer of the Travellers' and Reform Club-Houses, but it is more ornate than either, and retaining its chaste dignity. Its dimensions are 142 feet by 130. It has a noble state dining-room, 48 feet by 25, and a state drawing-room 68 feet by 25; but the great feature of the house is the saloon, 130 by 66 by 110 feet long, and which, were the lighting somewhat more satisfactory, would be in every way worthy of its magnificent contents. Scarcely less palatial in scale or style is Dorchester House, Park Lane, erected in 1839-43 for Mr. S. S. Holford, and the town house of Mr. L. E. Sumner, which is 216 feet by 130. It has a ground floor of Italian renaissance, as represented by Inigo Jones, than to the Italian adopted by Barry; and in many respects it is hardly so satisfactory, but it is a stately and imposing structure; its dimensions are 105 by 184 feet. The mansion of Mr. H. T. Hope, erected in 1848-49 by Professor Donladson, is in the designs of M. Desland, at a cost of 30,000L, also derives a word of notice, though in an artistic point of view it cannot be considered a happy effort. Like the mansions just noticed it is fitted up with great splendour, and like them it contains a singularly choice collection of paintings—indeed the finest collection of works by the Dutch and Flemish masters in this country.

Turning to the City, we are at once struck by the great improvement in the ordinary street architecture, which is there still more distinctly manifested than at the west-end, though at the west-end the improvement has not been inconsiderable. In the new streets have sprung up a long row of neat houses, and a succession of handsome buildings, unprecedented in London. Many of them are faced with stone, decorated with carving, and make considerable architectural pretensions; and all are built in a style of construction at once bold and substantial. The most striking feature of these buildings is the introduction of large windows and even seven stories being far from unusual. Of these warehouses the most noticeable are those in New Cannon Street and its vicinity, Wood Street, &c., but piles of 'offices' of almost or quite equal magnitudes have been built, or are building, in every part of the city which lies within the business boundaries, in the narrow alley courts, and lanes, as well as in the main lines of traffic. The most remarkable of these blocks of offices for extent is which are to be seen in the City, and the feeling of regret; for to make room for it one of the most artistic edifices in the city was pulled down. This was the Excise Office in Broad Street, built by James Gandon in 1768, of which it was remarked in the article London 'Penny Cyclopaedia,' vol. vi. p. 114, "its size and grandeur of mass, and greatness of manner, combined with simplicity, it surpasses everything else in the metropolis." Unfortunately on the removal of the Excise department no other use was made of it, and it was destroyed by fire in 1871. For a building, the chief merit of which is its size, there is a greater number of separate offices than any other in the kingdom.

Another class of city buildings which has done much to raise the character of London are the club-houses, which includes the banking-houses and insurance-offices. To the former several have been added by the joint-stock companies, as the Bank of London and the City Bank, which stand nearby.

To our former list of club-houses we have now to add some of a still more costly character. First of these in point of time was the Conservative, in St. James's Street, a stately edifice of the Roman style, erected for Sir Robert Smirke, by Mr. G. Basi and Sydney Smirke. The front of the old Carlton, by Sir Robert Smirke, has been made to give place to a more ornate façade by his brother Sydney. This, however,
opposite to each other in Threadneedle Street, the Australian Bank by the Royal Exchange, and several others of more or less architectural pretence; and among them must now be placed the South-Sea House, which was converted to the use of another company of as bad eminence as the corporation for which it was originally built—the British Royal Bank. Among private establishments may be named that of Jones, Loyd, and Co., in Lothbury, whose new office, by Sir John Soane, stands as tall and fine as anything in the money market. In connection with these the architect who has, in the streets of a city such as London, and shopkeepers in such a city must endeavour to render their places of business as attractive as possible. If houses are to be built expressly for shops, there can be no good reason why architects should not construct them as ornamental and beautiful as possible, and as is consistent with the purpose for which they are designed. In the great majority of recent shops everything else has been made to yield to the desire for as large a surface of plate-glass as possible; and hence what was intended as the most palpable fault in the shops just noticed—the want of sufficient apparent support in the ground story for the floors above—is the almost universal defect in the showier class of such buildings: and it is a fault fatal to all architectural pretence. The Arcade, a long and low building on the south side of Fleet Street, where the whole upper part of the house rests on a heavy carved cornice, and this, with all that it carries, on two immense sheets of plate-glass. Yet, if possible, the absurdity has been rendered even more palpable by the addition of a second floor, formed by throwing two or three houses together, is made in appearance to bear the whole superincumbent mass of brickwork upon a few slender glass pillars, and even the wider supporting pillars at the end are hardly larger. Of course in all these cases the upper parts of the building are really supported on wrought-iron girder, and for bearing these sufficient provision is made by strengthening the side walls, and by adding piers, &c., where necessary. Now, in this case, in the first place, the eye is given to the shop front an arched form, and thus inducing the appearance of sufficient support for the upper stories—a method which the shopkeeper will not in many instances allow, and when he does, will probably destroy the effect of by some gaudy decorative additions—why not accept the necessities of the case, and endeavour honestly to surround them? Railway and other recent engineering works have too much accustomed the eye to the weight of structure, and the absence of columns where it is visible to be adequately upheld. If the strength of the structure be satisfactory, there will be no doubt—none of the latent doubt even which unconsciously produces the feeling of distrust in the uninstructed observer—of the sufficient support and the sufficient pretence of the building. What seems to be wanted, then, is to frankly admit and not to endeavour to conceal the girders, and to give to the supports the greatest possible emphasis. Then trampled, equally with circular or pointed arches, architecture will be found to satisfy the eye the primary essential of security, while it alone can be found adequate for the varied requirements of the London tradesmen of this present century, as it alone can, within due limits, be adapted. To carry on the great subject of building as the basis of the history of the art, and to seek for the Artistic aspect of a subject in which the service which may be rendered by composition as an adjacent to well-executed brickwork in London street architecture, when it is used as composition and not as a deceptive imitation of stone. Before leaving the City we may just mention that two of the best known of its buildings have been considerably altered: the Bank of England both externally and in the interior, under the direction of Mr. Cockerell, who, as regards the outside, has, without changing any of the better parts of Soane's design, by giving elevation in certain portions of the
façades certainly improved its general character; and Newgate prison, of which the whole interior has been rebuilt on very superior plan, while the exterior—a classic example of prison architecture in general estimation—has with excellent success been associated with Newgate in the architectural mind, as being by the same architect, Dance, very similar in design as well as purpose, and its near neighbour, Giltspur-street Comptoir, has boon in some respects more convenient and attractive, and which, when the new city prison at Holloway was completed, this site is still unoccupied, as also that of the Fleet prison, pulled down in 1844. The new City Prison at Holloway is an extraordinary looking castellated pile, of great size and enormous cost, which was so very impregnable and of so much importance that the city of London Orphans' at Brixton, the City Industrial Schools, at Peuge, the South Metropolitan Industrial Schools, at Sutton, Surrey, the Whitechapel Industrial Schools at Forest Gate, Essex, and much less, was above 150,000. Scarcely so much can perhaps be said of the Great Western terminus, as it is rather remarkable as an engineering than an architectural work, but it has the great merit of showing adaptation to its purpose in a very unusual degree. And, to our thinking, is consequently the most satisfactory of all the London termini; it was the joint production of Messrs. Brunel and Digby Wyatt. Adjoining it is an hotel built for the railway Company by Mr. Hardwick, which, in size, architecture, and comfort, surpasses any yet constructed in London. The style—late French renaissance, with its bold masonic roots to the centre and turrets, the colossal terminal figures supporting the facade, &c. and with the spaciousness and interior artistic character a feature which has excited much notice. The terminus of the Great Northern Railway, at King's Cross, by Mr. L. Cubitt, merely presents, externally, brick terminations to the carriage sheds, with a lofty central tower; but inside the vista formed by the sheds is a most attractive and spacious interior. The Great Western Railway Company have built an hotel rivaling in size that of the Great Western; like that the style is continental, but rather strange than beautiful. None of the other metropolitan railway termini of recent erection have any architectural character.

Though we have left ourselves no room to describe, we must just refer to the great works completed and in progress in connection with the docks of London. Of those of the South Metropolitan, whose walls and warehouses are already a quarter-mile long, the London Docks at Shadwell, to make way for which many hundreds of houses have been removed. The object has been to afford greater facilities for the admission and unloading of the immense vessels which the requirements of modern commerce have called into existence, as well as to obtain increased room for general purposes. With this new basins of great depth have been formed, a new entrance constructed, with gates of enormous size, and other improvements of great power, as well as new warehouses and other works. At the Commercial Docks, on the Surrey side of the Thames, extensive alterations and improvements have been carried out. On the Pissow Marshes, just below Blackwall, a new construction has been made, with a basin of great area, and the new docks have been expressly designed to afford at present about 90 acres of water area, with entrances admitting large vessels than any of the old docks, though not, we believe, larger than the new works at the London docks in Maryland. At Woolwich a new dock of enormous size has been constructed, and vast works of various kinds erected, in connection with the arsenal, foundries, steam factories, &c., of the Government. And, finally, at Bremford a large new dock has been constructed, chiefly with a view to afford increased facilities for water carriage in connection with the Great Western Railway.

A few words on some of the larger works resulting from the progress of sanitary reform will conclude what we have to say respecting London. Great has been the protracted struggle, the city corporation were compelled, in 1852, to remove their fondly cherished Smithfield market; but it is due to them to say, that when compelled to provide a new cattle market in the suburb instead of in the centre of the city, they succeeded. A great deal of money has been expended on the site chosen was an elevated and very convenient one, the notorious Copenhagen Fields, adjoining both the Great Northern and North London Railways. The market covers 100 acres, but a new cottage house accommodation, with provision for cattle markets has been done with a bold disregard of expense, which only a corporation wealthy as that of London, content
to look to a somewhat remote future for repayment, could have ventured upon. Though it is rather on account of its skilful arrangement and adaptation to its special purpose that the Metropolitan Cattle Market is to be regarded, yet it is not without many other architectural and utilitarian advantages—banking-houses, and some of the offices are in very good taste, and its lofty central tower forms not only a prominent feature in the landscape for many miles northward, but gives an air of completeness and unity to the whole design of the Metropolitan Cattle Market, with all the details of its arrangement, is due to the city architect, Mr. Bunning, who also, two or three years before, had rebuilt Billingsgate Market in a very skilful manner, and with a style of neatness and grace, charmingly appropriate.

In 1852 an Act was passed rendering it unlawful for any water-company drawing its supply from the Thames, to take such supply after a certain day from any part of the river below Teddington lock. The several companies accordingly at once set about the construction of very extensive works—the Grand Junction, the West Middlesex, the Vauxhall, and the Southwark, at Hampton; the Chelsea and the Lambeth just above Kingston. The works at these places are some of them on a magnificent scale, the entire new works, for example, of the Chelsea Company, rendered necessary by the Act, have cost 450,000. The water is conveyed from Hampton and Kingston, in mains of from 30 inches to three feet in diameter, to the reservoirs of the several companies in the outskirts of London; the companies are passed under the Thames at Richmond by means of the coffer dams; those of another company are carried above the bed of the river, near Putney bridge, on piers formed by Mitchell's screw piles. But even more extensive works have been already begun upon the Thames, which, in works near the head of their river (including the drainage and diversion of the sewage of the town of Hertford), in forming capacious new reservoirs, and covering their old ones, &c., have expended considerably over half a million. Very extensive new works, and alterations in existing works, have also been carried out by the East London, the Kent, and the Hampstead companies.

The result of these vast operations has unquestionably been an improvement in the quality of the water supplied to the inhabitants of London. The Registrar-General, in his Report on the Health of London for the year ending April 18, 1855, says that the London water "contains less than half the previous amount of impurity. A gallon of water of the Chelsea Company formerly contained from 37 to 66 grains of extraneous matter; the Southwark water contained from 23 to 73 grains; while the analysis now shows that only 21 grains of extraneous matter are contained in a gallon of the water of the Chelsea Company. In several of the other companies a still smaller quantity of extraneous matter is found (in the West Middlesex only 17'64, in the Grand Junction 17'76 grains); but then the water, of course, was always purer than that of the former. Still it is very questionable whether small quantities of extraneous matter when so great a quantity of water has been used and costly an alteration was rendered compulsory,—the legislature might not well have gone further, and prohibited the use of the Thames at all for the purpose. For before it has reached the place where the supply is now drawn, it has been polluted by the drainage of Windsor, Chertsey, Staines, and other towns, and, as Mr. Ranger, the Superintending Inspector of the General Board of Health, has pointed out in his Report on the Sewerage, &c., of Aldermaston village, the new sewage of works of the city at Aldermaston have been so constructed as to have "their outfall into the Blackwater river . . . one of the tributaries of the Thames, entering the latter above the point from which a very large portion of the London supply is now taken, and thus a new source of pollution" has been introduced. In fact, it is stated in a Report just laid before the House of Commons by the Royal Commission appointed expressly to inquire into the best mode of distributing the sewage of towns that "the Thames, before it reaches works of the city at Aldermaston and a part of London is at present derived, receives the refuse of districts containing upwards of 700,000 persons." Under the circumstances, it would therefore be consolatory to believe, with Mr. Ives, "that the commission and armoury employed by the Metropolitan Board of Works to report on the Main Drainage of the Metropolis,—that this is of comparatively little consequence, Thames water being, in fact, a new disinfectant; "sewage matter, they say, "being poured into a much larger volume of fresh or fresherened water, becomes immediately oxygenised, and ceases to exist as a noxious and offensive agent."

Of the rival plans for intercepting the main drainage of the metropolis, as they are yet only plans, we shall not give a detailed description. It will be sufficient to say that the government referees and the engineers of the Metropolitan Board of Works were directed to proceed upon the basis, that a vast intercepting sewer extending on each side of the Thames was agreed upon, and that the question was to settle the distance from these metropolis boundaries to which it should be carried, the whole question has been re-opened by the Royal Commission mentioned above, who have just laid before the House of Commons (April, 1856), the outline of plans for an intercepting sewer reaching at once the embankment scheme of the Metropolitan Improvement Commissioners of 1844. The embankments they propose to be made to contribute to the beauty as well as utility of the river, the relief of the over-crowded streets by means of advanced terraces which are to afford connecting lines between London and Westminster, and the connection of railways on the southern side of the river; while the sewage is to be received into reservoirs in the embankments at the mouths of the existing main sewers. But it has been there deodorised and purified, the liquid part is to be permitted to flow into the river, and the precipitated matter to be carried away for agricultural purposes or discharged into the sea. Of the desirability of such an embankment, as they term it, they say it is "the most important part of the scheme is more questionable; but the Commissioners are sanguine as to its practicability, and they assert that the reservoirs and apparatus would be hidden beneath the surface, and that no matter whatever is dropped into them they estimate at 3,250,000, which is some 500,000 less than the intercepting sewer scheme of the Metropolitan Board, and 2,200,000 less than that of the Government referees is estimated to cost. But this reminds us that among the Metropolitan Board's improvements we have not mentioned the embankment of the Thames between Pilimico and Cheaps, a very excellent work, and thoroughly well executed, but which, estimated at 62,000, has cost 112,000.

Among new water sanitary improvements in London we must not pass unnoticed the substitution of spacious suburban or more distant cemeteries for the crowded churchyards of the city. Of new cemeteries the most remarkable is the London Necropolis, or Woking Cemetery, formed by a private company, which under powers of an Act of Parliament purchased 2100 acres of forest heath land, extending upwards of four miles along the line of the South-Western Railway, towards Farmborough and Pirbright. Of this land the company have constructed a vast number of a slightly undulating heathy tract, singularly quiet and picturesque in character, as a cemetery, and built chapels for the use of the members of the establishment and nonconformists, who, in consequence, have been numerous; and they are also provided for the exclusive use of the cemetery, in London, and special trains carry the funeral direct from it into the cemetery—a short line of railway having been constructed for the purpose. Funerals are thus conducted with economy, privacy, a careful regard to the feelings of mourners, and in all respects with singular propriety. As near to the best mode of interment as in the present state of society is perhaps practicable, appears indeed to have been attained. In connection with no other cemetery, we believe, has there been made such judicious arrangements for the conveyance of funerals from London—a matter of great consequence where the cemetery is at some distance from the city, and one which, like some other sanitary improvements, presses with peculiar severity on the poor. A very extensive and well-arranged cemetery has been formed by the City of London at Ilford, Essex; Marylebone and St. Pancras parishes have constructed theirs at Finchley; Lambeth parish has one at Tooting, and others newly formed are to be seen on every hand. Necropolis and cemetery towns have been devised and are springing up.

Turning to the Provinces, we can do little more than repeat our former statement, that great as has been the progress in architecture and public improvements generally there has been nothing of like importance to the provinces as the propitium made equal or nearly equal progress. We can only venture in vindication of this statement to refer briefly to a few particular instances. At Liverpool this has been eminently the case. St. George's Hall, designed by Mr. H. L. Eimers, but, in consequence of his death, completed by his
Cockrell, may not only be fairly placed in comparison with any similar building in London, but without hesitation be pronounced in many respects the finest, as it is undoubtedly the richest, recent example of a Romano-Corinthian edifice in the kingdom. The hall itself, 168 feet long, 100 feet wide, and 80 feet high, and over 200 feet in circumference, is a healthful guardroom for a party of sixteen columns without a pediment at the side. It is not impervious to criticism, perhaps, but undoubtedly St. George's Hall is one of the greatest architectural works of the day. But the Corporation of the Collegiate Institution, a large and handsome Tudor collegiate structure, also by Mr. Elmes; the Sailors' Home, a spacious Gothic building by Mr. Cunningham; the Branch Bank of England, by Mr. Cockrell, &c; but perhaps the most characteristic of the new buildings of Liverpool are the extensive and costly piles of offices, which are as much superior to similar buildings in London as the Manchester warehouses are to the warehouses in the City. The Docks of Liverpool, with vast ranges of connected warehouses, have been increased in number and extent, at an outlay of several millions sterling, and are now probably unrivalled. The floating stages on the Mersey, for landing from steamers, likewise claim a word of notice: one, at Prince's Pier, finished in 1845, cost £150,000; but another, at Berry Street, cost £140,000. Liverpool is one of the towns which has provided itself at a great cost with a supply of pure water from a distant source. Whether as a rival or an adjunct, its neighbour on the Cheshire side of the Mersey, Birkenhead, cannot be overrated, and its population is rapidly increasing. Foremost, as forming a sort of central point of the city, is the Exchange; which as lately enlarged affords the most spacious room, we believe, in Europe, for the meeting of commercial men, and both externally and in the inside is a very admirable work of its class. Free Trade Hall (by Mr. Walters), is in its title as well as its purpose, a structure characteristic of Manchester, and moreover a very fine building. Other buildings of a semi-public character are the Theatre Royal, over which Mr. John Pink, the bank of Messrs. Haywood; the Manchester and Salford Free Library; churches, chapels, synagogues, &c. But indisputably the warehouses form the distinctive feature of Manchester in an architectural point of view. They are very numerous and of increasing size. There are for the most part of great size—one, but we believe it is the largest in Manchester, built for Sir James Watt, the late mayor, by Messrs. Travis, is of the enormous dimensions of 300 feet long, 90 feet deep, and 100 feet high, three of the fronts being wholly of stone. And these warehouses are constructed in the most substantial manner, of stone or of excellent brickwork, with stone quoins and dressings: 'compot' is not in repute in Manchester. The style usually adopted by the merchants of the city, is called the 'simplified Romanesque,' which is in most instances carried out (as for example in those designed by Mr. Walters) with great refinement and finish, the carving and details being often worthy of a London club-house. The bulk of the London warehouses would certainly stand in no way with many of their Manchester prototype. A good beginning has likewise been made towards the embellishment of the city and suburbs with public monuments and parks. The front of the infirmary has been laid out as a hospital, and the entrances to the new buildings of Wellington, Peel, John Dalton, and James Watt, have been erected. New streets have been opened in the city, and old streets have been widened. The drainage has been greatly improved; and an ample supply of water has been brought from a spring-fed reservoir on the outskirts of the town. And outside the city three new parks have been formed: two of which, Queen's Park, Harpurhey, and Peel Park, Salford, are very attractive resorts.

Birmingham has hardly kept pace with the two great towns of Lancashire: yet it has added some new buildings worthy to rank with its noble town hall; as for example the grammar school, the new hall, the music hall, the midland institute now in progress, and some others. It has also its park; but we cannot add that it has had a government house. The Victoria Rooms have been done. The Victoria rooms is a spacious and very noble building for musical festivals and public meetings. The guildhall has a façade which is rather a favourable example of the Tudor period, but the interior is ill-arranged and undignified. The St. Paul's Church is one of the most recent additions to the architecture of the old city, and both are more than ordinarily ambitious in design. Turning from our manufacturing and commercial to our university towns, we find no falling off, though the architectural seal has taken a different direction. At Oxford the handsome range of buildings by Mr. Cockrell, called the Taylor Institute and University Galleries may be taken as marking the close of the passion for classic art in that university. Oxford is now, and has been for some years, the head quarters of mediævalism, and there the ('ecclesiologists') hold unquestioned sway. Perhaps nowhere else can the good and the evil of the Gothic revival be more distinctly seen. For years past the grand old city seems to have been raised up to the gothic builder and the gothic restorer. It would be idle to attempt an enumeration of the works which have been accomplished. Almost every college has added a new front, and often a new chapel, or has made only a little addition to its existing architectural treasures, or restored and re-edited its old ones. Many of the new works are of great beauty and richness, as could not indeed fail to be the case, and one is constantly struck by the promptings of a zealous love of Gothic architecture, a love with which no niggard hand—was entrusted to architects already famous for their peculiar devotion to this branch of the art. It is, perhaps, not too much to say, that some of the new works are worthy to stand beside the glorious buildings which surround them. But we cannot afford no such liberal praise for the so-called 'restorations.' They may have been well done professionally: they may have been correctly performed according to ecclesiological conceptions: but the buildings which have been restored are not now the buildings we knew a few years back, venerable in their hoary and unmistakable antiquity. They have been, too many of them, made to wear the gay drapery of youth upon the seared and beading frame of age. They now consequently exhibit neither the solemn majesty of the old, nor the lightness and beauty of the other. Our ancient Gothic structures—marvellous in the grandeur of their forms, in the evidences of mental power and artistic fancy, in their quaint carvings and playful details, in their beauty of composition, on which the cultivated and the uninstructed alike gaze with awe and wonder and endless admiration—ought only to be touched with a reverential hand. Our fathers, bowing before the sovereignty of the Greek and Roman, regarded our glorious medieval art as no longer worth the labors of our own artistic imaginations; and they altered, improved, or destroyed them with almost equal indifference. But their contempt was, we cannot but think, less dangerous than our too ardent love. They thought it folly to spend time over the rude structures of the dark ages, when they could study the temples of the brightest days of Greece and Rome, or of those enlightened times when the love of antiquity was restored to the scholars of modern Europe. Such foolish fondness have sought to replace the decaying vestige in which the object of our affection was clothed, by one as exactly resembling it as we could contrive to fabricate, forgetting, till too late, that the new and gay drapery is after all but a modern fiction, and that the true adornment which we have replaced was the only true one—that we have indeed copied, but in copying have destroyed it. 'Restoration' in truth is for the most part a mistake. Ancient buildings are not to be restored, but only preserved. To rescue ancient statues—where jealous care from the chisel of the modern artist. If anything can be done to arrest their decay, well: but it must be done so as not to remove, if possible, a hair or a finger-sail of the original—assuredly not to substitute for it anything so artificial as a pasteboard. We ask the reader what the chipped and battered fragment we have removed was in its pristine condition. As well might the Theseus or Ilyssus in the British Museum be submitted to the 'restoring'
chiel of Westminster or Bagby, or any other living Phidias, as our cathedrals and colleges be subjected to the tender mercies of modern representatives of the ancient builders. We are not, of course, objecting to necessary repairs, or even, where imperative, to rebuilding; but simply to the destructive process which takes place in the caricature of ancient work (usually the carved details and secondary features which are the characteristic signatures as it were of the old artists), and replacing them by new work intended to represent (and therefore to form a deceptions imitation of) the old.

Cambridge has proceeded somewhat more slowly of late than the sister university with its medieval reproductions and restorations, but it too has made a real architectural advance. So when the present century Wilkin raised amidst the plaudits of enthusiastic gowmen, would now excite a shout of universal execration. But Cambridge retained longer than Oxford her love of the classic orders, and some of her latest works of that kind are of a very superior character—as the library by Cockerell, and still more the Fitzwilliam Museum, a work of much beauty and stateliness.

But not to dwell longer on particular towns, we may point to the number of the different kinds of public buildings which have been lately erected in every part of the country as the best evidence of the reality and extent of architectual progress. In ecclesiastical edifices the progress has been something wonderful. During the last twenty years churches have been built in almost every part of the country, and a very large proportion of our ancient cathedrals and parish churches have been repaired, or as it is termed 'restored.' As in London, so through the country, all the recent churches have been in the English style, and it is difficult to say which is the greatest work of the age. The most prominent, if not the most original, is the new church at the Church Missionary College, St. Augustine's, Canterbury, built by the munificence of Mr. Hope, and which is so admirable a specimen of the abilities of Mr. Butterfield; and the numerous proprietary and other churches of various descriptions in the towns, such as Trinity, Scott; at Cheltenham, by Mr. Wilson; St. John's, Hurstperpoint, Sussex, by Mr. Carpenter; at Cuddesdon, near Oxford, by Mr. Street; the Lansdowne College, Bath, by Mr. Wilson; the Wellington, at Sandhurst, &c.; theological institutions belonging to the Independent body: at Winchester by Mr. Scott; at Cheltenham, by Mr. Irwin; New College, St. John's Wood, by Mr. Emmett; and at Spring Hill, near Birmingham, by Mr. James—all spacious and handsome edifices in the Tudor style and the perpendicular. A similar in purpose and similar in architectural style of the Wesleyan Methodists, at Richmond, Surrey, by Mr. Trimen; at Taunton, by Mr. Wilson; and the school at Kingswood, near Bath, by the same architect.

Of institutions the town and city churches the number has been surprisingly large. We might mention new Town Halls, at Leeds (a work of a high order of merit by Mr. Brodrick); at Colchester (Doric, by Blore and Raphael); at Ballymena (Doric, by Mr. Jones); at Whittlesby (by Mr. Rowe); at Alfreton (by Mr. Wilson); at East, Suffolk (by Mr. Lamb); at Chatham, at Halifax, at Leamington, Stockton, Bilston, Chertsey, Louth, and very many other towns: Market-places at Bolton, Wolverhampton, Stockport, Swindon, Worcester, at Leeds (a very fine one, costing 14,000l.), at Ashby-de-la-Zouch, at West Hartlepool, and elsewhere; Corn Exchanges, on some of which a large amount of money has been expended—at Colchester (by Raphael and Brandon); at Wolverhampton (by Mr. G. H. Atkinson); at Cheadle (by Pettington); at Southport, at Grantham, at Hitchin, at Louth (a handsome Venetian pile, by Mr. Bellamy); at Banbury, at Hemel Hempstead, at St. Albans, at Grimsby (Elizabelland, by Bellamy and Hardy); at Gloucester (a large and ambitious Romanesque edifice, by Medland and Maberly); at Alcester (Italian, by Mr. Holmes), &c.; Assize Courts at Reading (by Mr. Clary); at Taunton, at Swansea, &c.; County Courts, Post-Offices, &c.; Industrial Halls (some of the very recent ones, like that at Bradford, are of the most extraordinary and elaborate character); Scientific and Technical Colleges (of which there are a number in the large towns); Botanic Gardens, &c.; in this age of great public employments, works; Lyceums, Mechanicas Institutes, Free Libraries, Baths, &c.

Beyond the limits of the towns among the largest and most costly, and from their site and character often the most remarkable modern buildings, are the County Lunatic Asylums, but it must suffice to refer to them thus generally. The County and Borough jails are often curiously enough works of an inexcusably ambitious architectural character; the Royal Naval and Military Colleges; the Houses of the Corporation; the Protestant and Catholic Roman Catholic, must likewise be named in this connection.

Of industrial establishments of a more pleasing order—those of a more useful character—such as the Northern Gas Company's works; the extraordinary manufacturing village of Mr. Titus Salt's at Saltaire, near Bradford, and other great manufactories of recent erection—were we should be glad to speak, for they, in their architectural character, and in their admirable arrangements, are among
the most striking evidences of material improvement in the
the country. But we must pass them by, as we must also pass by
the works of públic companies, at Plymouth, Portsmouth, Chatham, Su-
derland, Great Grimsby, Cardiff, and elsewhere, vast as they
are in extent, and costly but most important in character;
and the equally magnificent works which have been in pro-
gress, both for the inshore and faro-reaching navies. Such
mariners harbours of refuge from the perils which beset
them. The defensive works which are erecting on the
more vulnerable parts of our coast, and for affording addi-
tional protection to our naval ports and arsenals, hardly
people the title of 'defensive ', as such has been so ill
improved. Such an article ought scarcely to conclude without at-
least a reference to the great naval and military hospitals which
have been recently erected or are in progress at Plymouth,
Portsmouth, Netley, Chatham, &c.; and although we have
heard much of deficient barrack accommodation, even that
must be largely increasing, and ought to be rapidly improving
when we see by parliamentary returns that in a single year,
1866-7, upwards of a million sterling has been spent in
building and improving hospitals and barrack accommoda-
tions 608,996l. repairs 292,745l. Of the many mansions
which have been erected in the country we must also refrain
from speaking, though the list is headed by her Majesty's
House at Carlton House, London, and the Prince of Wales
Improvements. Through some length, we have yet but very inade-
quately set forth the progress of public improvement in England
during the last twenty years. In Scotland and Ireland
architectural progress, taken as a whole, has not been propor-
tional to that of the sister country; yet when we look at the
national buildings which have been erected in Edinburgh
and Glasgow, the unirailled railway termini and some other
recent buildings in Dublin, the warehouses and public works
in Belfast, the Irish Queen's Colleges, &c., we cannot but
feel that Scotland and Ireland, as well as England, have
made a great stride in the path of architectural progress
during the past twenty years.
PUBLIC LIBRARIES. [LIBRARIES, PUBLIC, S.]
PUFPlNS. [PETREIA].
PUGIN, AUGUSTUS, an eminent architectural draftsmen,
wax a native of France, but settled in London at an
early age. He was engaged as a draftsman and assistant by
Nash, with whom he remained many years. He then found
employment in various parts of the kingdom as an
architectural drawings for engraving; one of the most impor-
tant of his earlier works being the buildings in Ackerman's
'Microcosm of London,' 1808-11. He also made the draw-
ings for this great work, consisting of Plans, Elevations,
Sections, and parts at large; calculated to exemplify the
various styles, and the practical construction of this class of admired
architecture; it was completed in 1823, and forms 2 vota.
folio and 4to, containing 1,4 plates, with descriptions, chiefly
by M. E. J. Wilson. In 1824 he commenced, in conjunction
with Mr. John Britton, 'Architectural Illustrations of the
Buildings of London,' also completed in 2 vols. 4to; and
with the same gentleman he published, in folio and quarto
1828, 'The Survey of the Cathedral and Colleges of England and
France.' In 1832 Mr. Pugin made the drawings for a work entitled 'Paris and its
Environs displayed,' and in 1831 he prepared, with the
assistance of his son, 'Gothic Ornaments, selected from various
instances in England and France.' He died December
19th, 1832.
PUGIN, AUGUSTIN WELBY NORTHMORE, son of
the preceding, was born in 1811. Instructed by his father in
the principles of architecture, he early acquired under him
the useful and practical information necessary to assist in
collecting materials in Normandy and England for his
works on Gothic architecture. [Pugin, A.] His first dis-
tinct employment was as assistant to Messrs. Gieves, in
painting the architectural scenery in her Majesty's and Covent
Garden theatres. In 1838 he designed for Mr. Pugin the
architecture in Windsor Castle, and designs for plate in the medie-
val style for Messrs. Randell and Bridge. In 1833 he removed to
Ramsgate, and commenced preparing for publication a
series of ' works illustrative of the furniture and ornamental
work of the Gothic period, in the Nones for Gothic Furniture, in the style of the Fifteenth Century,' and
'Designs for Iron and Brass-Work, in the style of the XVth and XVIth centuries.' These were followed in 1836 by 'Designs for Chimneys, with their
Ancient' Timber Houses, 'all of which met with a ready sale, and
undertook not a little to stimulate the growing taste for Gothic
forms. His next work was one that, by its caustic and irri-
tivating way of setting forth some home-truths, aroused not a
little the profession. In 1839 he published 'The Noble
Edifices of the 14th and 15th centuries, and similar
buildings of the present decay of Taste;' a second and im-
proved edition of it was published in 1841.
Mr. Pugin had by this time joined the Roman Catholic
Church, to the service of which he henceforth devoted his
best energies. Having received a handsome bequest from an
aun, Mrs. Welby, he built himself a fanciful residence in
the neighbourhood of Salisbury, and removed there, resolved
to devote himself to the study and practice of the true
architecture of the middle ages. Having found in the Earl of
Shrewsbury a warm patron, Mr. Pugin soon obtained oppor-
tunities of exerting his abilities; and during the few years
he lived, he may be said to have raised the profession he was called upon to erect a large number of Roman Catholic churches,
convents, and schools, than has probably fallen to the lot of
any Englishman since the Reformation. The following list,
we believe, includes his chief works,—(we are indebted for
it, and many of the other facts contained in this notice, to a
memoir of Pugin by his friend Mr. Talbot Bury, which
appeared in the 'Builder' shortly after Pugin's death):—
- The cathedral church at St. Marie at Derby, one of his earlier and
most pleasing works; St. Chad's, Birmingham; three
chambers at the Red Lion Inn, Coventry; the University
and convent at Edge Hill; churches at Oxford, Cambridge,
Reading, Kenilworth, Stockton-on-Tees, Newcastle-upon-
Tyne, Preston, Keighley, Rugby, Northampton, Stoke-upon-
Trent, Bromwood, Woolwich, Hammersmith, Fulham, Ponte-
fract, St. Edward's near Ware, Buckingham, and St. Wilfred
near Alton; a church, and a convent and chapel, at Notting-
ham; convents of the Sisters of Mercy at London, Birmingham,
and Liverpool; a priory at Downside near Bath;
- the churches of the Roman Catholic clergy, and
monasteries, with schools and priests' houses attached;
at St. George's (Southwark), Kinnerly, and Enniscoe. To
these must be added the extensive and costly works executed
in the church at Liverpool, the church at Dublin, the
convents, besides the alterations made in the mansion, of a
church house, and monastery at Alton Towers; and a church
at Cheadle, which has the most splendid interior of any of
his churches. The very pretty gateway to Magdalen College,
Oxford, is one of the few works executed by him for a
Protestant body; indeed he is said to have refused to
accept any commissions for Protestant places of worship.
The list of works given above would in truth seem to have
been more than sufficient to exhaust the time and energies of a
man who ceased working at the age of forty; yet he was
chiefly employed during his last years in designing and super-
intending the ornamentation of the New Palace of West-
minster, which probably owes its somewhat extravagantly
original character and expense to the influence of the Parlia-
mencey. But, besides the practice of his profession, he found
time to add to its literature a second and revised edition of his
'Contrastes'; a treatise on the 'True Principles of Pointed
or Christian Architecture, 1841; 'An Apology for the
Re-
vival of Christian Architecture,' 1843; 'A Glossary of Ecclesi-
siastical Ornament,' 1844; a treatise on 'Floriated Ornaments,'
1849; and 'A Treatise on Chancel Screens,' 1861. We
ought also to add that he was connected commercially with the
house of Mr. James Burton, of Tunbridge Wells, in the
eclesiastical brass-work from his designs; and he is said to
have filled up his leisure hours with landscape-painting.
Mr. Pugin had always been fond of the sea,—indeed it is
stated in one of the biographical notices of him that he once
adverted 'as he stood on the cliffs of Dover, for many
minutes, the 'sailing into Holland,' though it is difficult to see when that
time could have been)—and having realised by his profession a
handsome sum, he purchased an estate at Ramsgate, in order at once to enjoy his favourite element, and carry out unfettered his notions of architectural propriety. Here he expended all his property in erecting for himself a house, a church, schools, &c., the last of which was dedicated to St. Augustine. As he conceived in life his religious feelings took more and more entire possession of him. He now (1856) wrote and published 'An Address to the Inhabitants of Ramsgate,' 'An Earnest Appeal for the Revival of the Ancient Plain Song,' 'The Present State of the Church of England,' Catholics, and other pamphlets of a religious character. At length, overtasked with all this excessive labour and excitement, his intellect began to give way, and in his fortieth year it was deemed necessary to remove him to a lunatic asylum. For a brief space his mental powers were so far restored that it became practicable for him to return to his home at Ramsgate; but his life was ebbing, and he expired there on the 14th of September 1852, three days after his return. He was buried in a vault of his own church of St. Augustine. He had been three times married, and shortly after his death a pension of 100l. a year was granted to his widow from the Civil List.

As will have been seen, Mr. Pugin was a man of extraordinary industry and energy, and he possessed a very unusual amount of knowledge and great ability. He attempted too many things, and he worked too much and too fast to produce many great works, even had he been a man of original power; but in truth his was not a creative mind, and he lacked comprehensive thought. His great principle was, that, except as to size, the architect should aim at a faithful reproduction of an ecclesiastical edifice of the medieval period; or, as he stated it in his 'True Principles of Pointed or Gothic Architecture,' 'We may indeed improve in mechanical contrivance and edifice its construction—we may even increase its scale or grandeur; but we can never successfully deviate one tittle from the spirit and principles of Gothic architecture. We must rest content to follow, not to lead. We must indeed widen the road which our Catholic fathers formed, but we can never depart from their track without a certainty of failure being the result of our presumption.' Following such a dogma, it is evident that the highest success must be a respectable imitation. But even on his own principles, few of his works are entirely satisfactory as a whole, in particular parts and in details he is generally very happy, and some of his interiors have a rich and pleasing effect. His writings have had a powerful influence on the taste and practice of professors of architecture, and still more on the taste of ecclesiastical amateurs, and the influence has not been entirely a happy one. More than any single man perhaps has he been the cause of that pernicious fashion which has predominated during the last fifteen or twenty years, of building modern churches in all their parts on the precise model of the churches of the middle ages, although—at least in Protestant churches—the forms of worship and the requirements of the congregations are changed. In Pugin it was consistent: in his Protestant disciples it is absurd.

PUNISHMENTS. [OFFENCES AND PUNISHMENTS, S. 2.]

PUNJAB, or PANJAB. [HINDUSTAN.]

PURTIE, JOHN, of the East India Company.

PUSEY, PHILIP, elder brother of the Rev. Edward Bouverie Pusey, D.D., was born in 1799. Having succeeded in 1829 to the Pusey estates in Berkshire (held originally by the tenure of a horn, which has been in possession of the family upwards of 800 years), he became member for the borough of Chippenham in 1830, and in the following year for that of Caselh. In December, 1834, he was elected for Berkshire, for which he had been a unsuccessful candidate previously; and he continued to represent that county until the dissolution in 1832. A Conservative in politics, and a decided supporter of the Corn Laws, on finding that agricultural protection, however desirable he might deem it, was practically unattainable after the passing of the Corn Law measures by Sir Robert Peel in 1846, he, instead of continuing with the bulk of the Protectionist party to agitate for a repeal of the free trade measures, urged the agriculturists to make the best of their position, and to adopt without delay every improvement which scientific investigation and practical experiment had shown to be beneficial, in order to enable them to compete advantageously with the foreign producer. Already well known as a practical agriculturist, and as one who had given his attention to, and carefully watched and tested, every scientific improvement which had been introduced from time to time into the system of draining, ploughing, and reaping, his advice was listened to with respect, and his various practical papers in the 'Agricultural Journal' were received as authoritative, and probably to the influence of his character and sober judgment may be attributed in no small measure the great advance which has been made within the last few years in every department of English agriculture. Mr. Pusey was president of the Royal Agricultural Society of England in 1854, and one of the chief contributors to the Journal of that society, which he also edited for several years. He died July 6, 1855.

QUATREMÈRE DE QUINCY, ANTOINE CHRYSTOS-TOME, a celebrated French archæologist, was born at Paris, October 28, 1758. Before the outbreak of the first revolution he had made himself known by his researches on ancient art; a memoir on Egyptian architecture was crowned by the Academy in 1785, and in 1786 he commenced his 'Dictionnaire d'Architecture,' which he did not complete till more than forty years later (1829). In 1790 he published 'Considerations sur l'art du Dessin en France.' But his political opinions having led to his election as a member of the Legislative Assembly in 1790, he at once took his place among the party known as constitutional monarchists. He in 1791 became obnoxious to the revolutionists, and during the Reign of Terror was thrown into prison, where he remained thirteen months. On his release he appears to have continued to act with those who were opposed to the new order of things. In the affair of the 13th Vendémiaire (Octoer 5, 1795), he took part in the Convention, and was in consequence tried 'par contumace' and condemned to death; but he managed to secrete himself. When power had fallen into new hands he again emerged, and was in 1797 elected to the council of the Five Hundred for the department of the Seine. But true to his royalist principles, he set himself in opposition to the Directory, and in consequence was one of the first on the list of the 19th Fructidor (9th September 1797) of those condemned without trial to deportation to Cayenne; but he was again fortunate enough to make his escape. After Bonaparte had secured his position, M. Quatremère de Quincy was permitted to return to Paris, though the object of an official imprisonment; but he appears to have thought it most prudent to quietly proseque his literary and artistic studies. On the Bourbon restoration his sufferings for monarchy were amply recompensed. He was named in 1814 by Louis XVIII., Intendant-Général des Arts et des Monuments Publiques, Censeur Royal, and Membre du Conseil d'Instruction. In the following year he became a Member of the Institute, and was appointed perpetual secretary of the Académie des Beaux Arts. At one time he seemed disposed to renew his political life, procuring himself in 1820 to be elected member for the department of the Seine, but he retired to his literary pursuits at the close of the session of 1828. He survived till near the end of 1849, but he had for some years outlived his faculties.

From the restoration, partly on account of his position as director-general of public monuments and secretary of the Academy, and partly from his great literary activity, M.
Quatremer de Quincy occupied a prominent and influential place among the French writers on the history and theory of art. He outlawed however his reputation as an archaeologist, for his learning was but shallow as compared with later scholars, especially those of Germany; and as a writer on the principles he furnishes of the subject he has much in common with the other writers of the day. Yet his work contains much valuable matter, and his speculations are mostly interesting, however unsatisfactory. The following, in addition to those already named, are his principal works:—"Lettres Adressees a M. Canova sur les Marbres d'Egitu," 1822; "De la Nature, du But, et des Moyens de l'Imitation dans les Beaux Arts," 1823—"the most original and the most satisfactory of his speculative works;" "Lives of Raffaello (1824), of the Most Celebrated Architects (1850), of Canova (1854), and of Michel Angelo (1830);" "Memoires et Observations sur les Antiques Restaurés d'après les Descriptions des Ecrivains Grécs et Latins," 2 tomos, 4to, Paris, 1826-29; "Sur la Statue antique de Venus découverte dans l'Isle de Miro en 1830;" and "Essai sur l'Ideal," 1837. He also wrote several pamphlets, discourses, and papers, as well as a great many dissertations in the "Magasin Encyclopédique" of Millin, and various lives in the "Biographie Universelle," besides numerous "éloges" read by him at the Academy: of these last he published a selection, of eight, called "Mémoires de deux grands philosophes," 1827; and "Recueil de Notices Historiques lues dans les Séances Publiques de l'Académie Royale des Beaux-Arts à l'Institut," 1827.

C. calisaya, and their extremities are invariably attached one to the other, their ends being by this means more elongated.

3. If we study with equal attention the bark of C. pubescens, which is a fibrous ill-defined structure. The external surface somewhat resembles the preceding bark, with the exception of a slight whitish marbling, formed by the continuity of the peridermis, and scirruses which may result from desiccation. The internal surface, as it is usually seen in the cross sections, but a transverse section shows us that it is principally composed of cellular tissue, in which the fibres form but a small number of irregular and concentric series in the interior half of the bark; and that which draws the attention at the first glance is the size of the fibre cell, each one being three or four times as large as those of either of the former varieties; the result being that several of them are attached and united together in bundles, which may be fully proved by the examination of a longitudinal section of this bark.

"As may be perceived, we have only spoken of Cinchonas which have been deprived of their peridermis, because it is in this state that they are now usually met with in commerce. If perchance they were again to be used with their peridermis and to export them in the same state, it would afford additional means whereby to distinguish them, but would not in any way affect those which we have just treated; for nothing would be easier than to remove the peridermis and to export the net surface and to export it so. As a result, the structure of all the Cinchonas bears more or less resemblance one or other of the three types we have spoken of, and on this plan there might be formed, without much difficulty, a series of groups comprehending all the Cinchonas. The purpose however now is not to distinguish these peculiarities, has been to facilitate the comprehension of a very important fact in the diagnostics of the different kinds of Cinchonas; that of the vast difference they present in their mode of fracture. However singular it may be, in the first instance appear to be, it is easy to prove that, to a certain extent, the chemical composition of the bark operated upon may be determined by its mode of fracture; or, more properly speaking, there exists a relation between the chemical composition of the bark and the nature of the fracture, being constantly proved by a particular form of fracture: smooth or corky where it divides the tunic or cellular covering of the bark; fibrous, stringy, or woody in those cases where it has affected one or other of the three forms of liver before described. Another fact which is now fully proved is, that the bark containing the largest proportion of quinine is that of the C. calisaya; and experience has shown us, that after the C. calisaya, the barks possessing in it the greatest quantities are precisely those which would most resemble this bark; for instance, those in which the peridermis is reduced to a single layer by the successive exfoliation of the outer tunic, or at least by their adhesion to the peridermis, experience other hand, have shown, to a certain extent, that the Gray Cinchonas (which we have generally found to be the young barks of other species) contain a larger proportion of cinchonine than quinine, and that many old barks which have retained the cellular coating they had when young, yield a proportionately larger quantity of cinchonine; from which circumstance we may conclude that quinine is contained in the liver, or, more correctly speaking, in the cellular tissue interposed between the fibres of the other, and that the cinchonine is principally found in the tunic or cellular coating. As to the tannin, it is found in larger quantities in this latter part than in the fibrous tissue—a fact which is easily determined with reference to the bark, which the external layers of the derm are more stumpy than the internal layers." ("Pharmaceutical Journal," vol. ix.)

The following are the specific characters of the Cinchona calisaya:—Leaves oblong or lanceolate, obovate, obtuse, swollen, often spiny, rarely acuminate, sparsely pubescent, or pubescent beneath; scrobiculate in the axils of the veins; filaments usually shorter than one half the length of the anthers; capsule ovate, scarcely equal in length to the style, which is shortly stigmatic at the base. Seeds frequently fringed, sometimes centriculated at the margin. Of this there are two varieties:—

C. C. vera. A tree with obtuse oblong-ovate or oblanceolate leaves.

C. C. americana. A shrub with somewhat acute-oblong-lanceolate or ovate-lanceolate leaves.

Both varieties are natives of Bolivia and Southern Perú. ("Pharmaceutical Journal," vol. ix.)
QUINTANA, MANUEL JOSÉ, a very eminent Spanish poet and patriot, remarkable for the depth of his feeling in both characters, and remarkable also for the strange vicissitudes of his long career, was descended from an Este- meduarda family of Madrid, where he was born on the 11th of April, 1772. He studied and took his degrees in canon and civil law at the University of Salamanca, where he became intimate with the poets Cienfuegos and Melendez, who introduced him to the friendship of Jovellanos (now the immortal docteur), and became a representative of liberal ideas in Spain. Quintana was from the first distin-
guished for his spirit of manliness and independence, and when he commenced his career as an advocate at Madrid, home, at the age of twenty, his friends assembled every evening, because he was an ordinary resort of those who were opposed to the degrading policy of Godoy, the all-powerful favorite of the day; while the house of Moratín, the dra-
matic poet [Moratín], the other literary focus, was the resort of those who paid homage to the minister.

From about 1795 Quintana became known as a poet only second to his friend Melendez, and in almost every case the themes he selected were of a large and lofty character, and treated in a corresponding strain. One of the finest odes in the Spanish language, is a tributary of his; but at the same time to his twenty-sixth year without ever prevailing the ocean, and in 1798 he was seized with so irresistible a longing to fill up the deficiency, that he made a journey from Madrid to Godoy, where he became an intimate pupil of the poet, and worthy of the occasion and returned. Such an incident would have been noticeable in any country, but it was par-
ticularly to that country and age, for, as Alcalá Galiano remarks, in his excellent history of Spanish literature, trav-
ingen example has not been equalled in the habits of Spanish life. Many of Quintana's other odes are scarcely less admirable than this, and they constitute by far his best title to posthumous fame. It may be remarked that the patriotism, which is the animating principle of almost every one of them, is a very Gallican, but at the same time, narrow feeling. Two of these odes, which will be found translated into English in Kennedy's 'Modern Poets and Poetry of Spain' (London, 1835), are on the introduction of Wellington into Amiens by the Spaniards, and the battle of Trafalgar. In the first, after celebrating the great dis-
covery of Jenner, Quintana exclaims—

"The gift of the discovery is the gift
Of chance; that let an Englishman enjoy,
But let Spain show her noble, generous heart," &c;

by conveying it to her colonies, apparently forgetting that England imported the discovery not only to her own colo-

nies, but to the Indies, which at that time were all Spain, in spite of their at first receiving it with insulting suspicion. In the ode on Trafalgar, the battle is represented throughout as between the English and Spaniards, the French not being even honoured with a name. This is as uncharacteristic as the usual long poem as a very generous compliment to the memory of Nelson by saying, "As an Englishman, I abhorred thees; but as a hero, I admire." These points are worthy of notice as characteristic not only of Quintana but of the majority of his countrymen.

In dramatic poetry Quintana was far less successful than in lyric poetry. As early as in 1791 he had contended for a prize offered by the Spanish Academy for a poem on the "Rules of the Drama" ('Las Reglas del Drama'), and in this production he expresses unbounded admiration for Corneille and Molière, makes but lukewarm mention of Lope, Calderón, and Moreto, and none whatever of Shakespeare, though, probably in conse-

quence of his friendship with Melendez, he had studied in England. In his own tragedies, of which he gave two to the public, the same line of thought is apparent. One of them, "El Duque de Visso" ('The Duke of Visso'), acted in 1801, is acknowledged by the author to be founded on an English play. "El Quixote," another of his tragedies, not only in the description of the villain's dream, is evidently taken from the well-known dream of Osmond in Monk Lewis's 'Castle Spectre,' but in other respects the resemblance is very slight. The other tragedy, "Pelayo," which is somewhat better, is a collection of pathetic desola-
tions, some of them fine when separately taken, but quite undramatic, and reading like passages from the author's odes.

Up to the time of the French invasion in 1806, Quintana's position continued one of great prosperity. As an advocate in spite of his liberal opinions, he held several important offices, among others, those of fiscal agent of the junta of commerce, secretary of the department for the interpretation of foreign law, etc. The liberal opinions of the patriot, however, man his reputation was constantly increasing. He edited a periodical entitled 'Variedades,' which was considered the best of its time in Spain. In 1807 he issued the first volume of a prose work, the 'Vidas de Españoles célebres' ('Lives of celebrated Spaniards'), communications which, however, was going on to Gonzalo de Cordova, the Great Captain. In the following year he published in three volumes a selection of specimens of the best Castilian poetry from the time of Juan de la Mora to the close of the 16th century, and appended to it a short history of Castilian poetry, supplying all the want of the kind that had before appeared, and which was afterwards rendered into English by Wiffen as an introduc-
tion to his translation of 'Garciasso de la Vega.' This was in the year of the French invasion. That great event had a very different effect on the three friends, Cienfuegos, Me-
lendez, and Quintana. Cienfuegos, seized by Murat, and sent a prisoner to the south of France, died of indignation at the treatment of his country and himself; Melendez passed over to the ranks of the enemies of Quintana became one of the literary antagonists of the French by far the most active and the most dangerous. He was the author of most of the manifestos of the insurrectionary Junta, the fervid eloquence of which supplied the French with documents of the first Cortes. His weekly periodical, 'El Semanario Patriótico,' was the leading organ of the patriotic party, and exercised great influence on the march of events, Quintana was as no uncomromising an advocate of liberal institutions against the French invader. The six years of the war were the most glorious of his long life. They were followed by six years of imprison-
ment. The return of Ferdinand VII. was to Quintana, as to all men who had earned his throne, a crown on his own head. Having been the advocate of the Cortes and of a constitution was regarded as a crime that called for punishment. He was suddenly seized and thrown into the fortress of Pamplona, where he was left imprisoned with no hope or promise of pardon, and debarred from all intercourse with his friends, and, not allowed access to pen and ink. In this state of rigorous incarceration he remained till he was released by the out-
break of Riego's insurrection, on the 1st of January, 1830. He was then at once set at liberty, restored to his old dignity and popularity, restored to his old offices and honours, and was named president of the department of public instruction, but he was no longer the man he had been before his imprison-
ment. His detestation of tyranny was still strong, and his powers of composition were not less, but he seemed to have lost the continuance of the new order of things, and with guarded prudence he abstained from making himself conspicuous in the ranks of the liberal party. When the second French invasion overthrew the constitution, he received the reward of his resignation in the crown of Spain, while his friends and companions took refuge in England and France. Commanded to leave the capital he retired to Cabezas del Buéy, the town in Estremadura to which his ancestors belonged, and there lived in obscurity and absolute poverty for some years. In this retreat he composed a series of 'Letters to Lord Holland,' with whom he had become acquainted at Madrid, which contain an eloquent and touching vindication of the proceedings of the Spanish Cortes, which were so much reviled by the French at the injustice with which they had been treated by England.

These letters, the last of which bears date in 1834, were, of course carefully concealed at the time they were written, and did not see the light till they appeared in a collected edition of Quintana's works in 1862. At the time of King Ferdinand's marriage to his third wife, Queen Maria Christina, in 1830, he sent an intimation to Quintana that he would be permitted to return to Madrid, if he would write an ode in honour of the event. The poet then showed the new king, it is said, that he had theretofore been that he had never written a line in praise of the powers that were, and his friends were at once grieved and astonished to find that he compiled. The poem was published and pronounced a complete failure, and a portion of it, although Galiano, an excellent judge, considered it the worst Quintana had ever written. The poet returned to Madrid, which no longer regarded as inflexible, and found him-
self on the road to fortune. Soon after he was named a member of the committee of the Museum of Natural...
RACZYŃSKI, EDUARD, a Polish nobleman of literary tastes and talents, was born at Poznań in 1766, the son of Count Philip Raczyński, a Polish general. Count Eduard entered the Polish army, and took some share in Napoleon's campaign of 1807; but on the fall of Napoleon I., when he became a simple Prussian subject, he withdrew from a military career. He travelled in Turkey in 1814, and published an account of his journey in one of the most splendid volumes in the Polish language, 'Dziennik Podroży do Turcji' (fols. Breslau, 1818, illustrated withnumerous plates). The rest of his life was chiefly devoted to literary pursuits. His 'Obráz Polaków i Polski' (Picture of the Poles and Poland in the 18th Century, 21 vols., Breslau, 1840, &c.), is a valuable collection of memoirs, most of them before unpublished. Another of his most prominent works is his 'Gabinet medalowy Polskich,' or 'Cabinet of Polish Medals,' in 4 vols. 4to (Berlin and Poznań, 1841-45), with a text in Polish and French. His 'Wspomnienia Wielkopolskie' (Memorials of Great Poland, 2 vols, with an atlas of plates), is also deserving of mention. The 'Codex Diplomaticus Majoris Polonie,' or collection of documents illustrating the history of Poland, which he edited, had been originally compiled by his grandfather, Count Kazimierz Raczyński; but a companion work, the 'Codex Diplomaticus Lithuanus,' was his own. Among other benefactions to Poznań, he founded a public library in that town, erecting a building for the purpose, presenting to it a collection of 1,000 volumes, and endowing it with a fund for the maintenance of its books. He was one of the first historians and antiquaries in Poland, to whom the Count gave the appointment. On the 30th of January 1845 Raczyński destroyed himself, by means of an ornamental cannon which was kept in his park. It was currently reported that the motive of the act was, that in looking over some old family papers, he had found that one of his ancestors had received part of the family estates as a bribe from Catharine II. of Russia to betray the cause of his country. The lady of Count Raczyński, who survived him, was the widow of Count Jan Potocki, also a Polish aristocrat, who destroyed himself thirty years before in 1815. His son, Count Roger Raczyński, who succeeded him, generously abolished the feudal dues that were payable to him by 42 inhabitants of the twenty-seven villages on the estates of the family.

RÄDETKY DE RADETZ, FIELD-MARSHAL, COUNT JOSEPH, was born at the castle of Trebince, in the Kistaiszer district, in Bohemia, on the 2nd of No- vember, 1766. He was the son of Count Peter Ernst the elder Radecky, and of the Barones Maria Bechyna. The family name was formerly spelt Hradecky. Having entered the army as a cornet, in the 2nd Austrian Cuirassiers, in 1784, he became sub-lieutenant, February 3, 1787. In 1788 he served in the Turkish campaign under Marshal Lacy, and was raised to the rank of first lieutenant for his services at the siege of Belgrade. When the Austrian army entered France in 1793, Radecky, then a captain, was sent to the new scene of war; and he was present in all the Italian campaigns from 1795 to 1800, serving alternately under Beaulieu, Wurmser, Altavilla and Melas, and distinguishing himself greatly at the battles of Arcola, Rivoli, and Marengo. Meanwhile, in 1797, he was promoted to the rank of major, and in 1799 he became adjutant-general to Melas, who soon learned to appreciate his zeal and gallantry, and repeatedly mentioned his name in his dispatches. For his gallant behaviour at the battles of Novi (May 16, 1799) and Marengo (June 14, 1800), he was created colonel, and appointed to command the Archduke Albert's cuirassiers, and received the order of Maria Theresa.

From the peace of Luneville, in 1801, to 1805, Colonel Radecky was not employed in the field; but at the latter period he was made major-general. During the contest at Aspern, May 21-22, 1809, when the place was six times retaken by the Austrians from the French, few officers contributed so much to the victory as Radecky. On the 1st of June he received the command of the 4th corps, with the rank of lieutenant-field-marshal. At the battle of Wagram, on the 6th of July, 1809, when the French army was defeated, Radecky was again in the thick of the battle. In April 1810 he was nominated commander of the military order of Maria Theresa. From that period until the end of 1813 his services were employed at home in the war-office.

During the whole campaign of 1813, when the tide of war had turned against Napoleon I., Lieutenant-Field-Marshal Radecky acted as chief of the staff to Prince Schwarzenberg; and the Austrian commander attributed the victory of Kulm mainly to Radecky's skill and gallantry. But his services were not yet over. On the 18th of October, 1813, he was appointed commanding general of all the Austrian troops in Germany, a post which he held until the end of the war. On the 18th of March, 1814, he was created field-marshall by the Emperor, and was appointed to the command of the newly-created Austrian army in Italy. He was in command of the left wing at the battle of Pavia, and on the 9th of March, 1814, he was made a field-marshall of Prussia. After the peace of Château-Thierry, he was appointed commander-in-chief of the army of the Lower Rhine, and was made a peer of the Holy Roman Empire. He was succeeded in this post by his brother, Count Paul Radecky, who was created a peer of Austria. After the death of Emperor Francis II., Radecky was appointed to the command of the army in Italy, and was created a peer of Austria.
he entered Paris, riding by the side of the Emperor Alexander. Radetsky was appointed in 1829 Commander-General of the Lombard Army and of the Neapolitan Kingdom; and in 1830, in his sixty-fourth year, after forty-six years of service, he was created field-marshal.

But it was the Italian insurrection, in 1848, which first gave Radetsky prominence as a Turkish general. As early as May 1848 manifest signs of a tumult and revolution were visible in Italy. The stringent rule of the Austrian government had long excited a ranncorous feeling in the Italians against their foreign masters, and they waited for an opportunity to reject the opressor and establish the liberties of their race. Austrian generals were scattered over an extensive line of operations. Consequently the insurgents were at first triumphant; the tri-color flag appeared upon all the towers of Italy, except those of Verona, Mantua, Legnano, and Peschiera; and Charles Albert, King of Sardinia, at Turin, made known his determination to throw off Austrian yoke. A dépêche was sent to Marshal Radetsky, and the terms obtained were: "that the Piedmontese army was to be withdrawn in two days from the Lombard territory; that the Austrians were to enter Milan on the 8th of August; and that the lives and property of the people were to be respected." The struggle was now virtually at an end. Radetsky's superior strategy, and the disunion of his opponents, rendered it an easy task for him to break up the Sardinian forces, and he was again master of Milan. A députation was sent to him by the citizens of Milan, and the terms of peace were concluded. Full of, and loaded with honors by his sovereign, he several times afterwards applied in vain for leave to resign his command. Not was it until the opening of 1847 that he obtained this permission, in a courteous letter from the Emperor, after a prolonged service of seventy-three years in the Austrian armies. He died Jan. 5, 1858, at Milan.

Radetsky married in 1798 the Countess Francesca Strasoldo-Güdenberg, by whom he has left a son and daughter.

RAFFLESIAEACE, a natural order of stemless leafless Parasitical Plants, consisting of flowers growing immediately from the prostrate roots of the cambial layer. The perianth is superior, with a 5-parted limb, thickened processes or calli either distinct or united into a ring being attached to the throat of the tube. The essential organs are combined in a column which adheres to the tube of the perianth. Anthers 3-celled, either distinct and opening by vertical slits, or combined together so as to become a multicellular mass opening by a common pore. Ovary 1-celled; placenta parietal. Fruit indehiscent. The species are rare, and of which the best known is Rafflesia arnoldi. Several species of Osuna and some Lycopodites. There are 10 species. Some of them are said to be styrical. Their perianth has a fugguid appearance.

Rafflesia Arnoldi, a Somatric parasite, is capable of containing 250 lbs. of water. The flower is said sometimes to have a weight of 14 lbs.

R. Patna is employed as an astringent and styptic in Java. 

St. Horsfieldi, R. Cunningham, and R. Rochussenii have similar properties.

The genera are Rafflesia, Supria, Brugmannia, Aponekhas, and Pilostyles. (Balflour, Classbook of Botany; Lindley, Vegetable Kingdom.)

RAGGED ROBIN. [LOCHINN, S. 1.]

RAGLAN, James Henry FitzRoy, Baron (previously Lord Fitzroy Somerset), was the younger son of Henry, fifth duke of Beaufort, by Elizabeth, daughter of Admiral the Hon. E. Boscawen, and was born in 1788. He received his education at Westminster School, and before completing his sixteenth year obtained a commission in the 4th Light Dragoons. In 1807 he attended the late Sir Arthur Paget in his embassy to Constantinople; and was in the same year placed on the staff of the Duke of Wellington. The following year he was appointed aide-de-camp to the Duke of Cambridge, in which capacity Lord Fitzroy Somerset was present in every engagement throughout the Peninsular campaign. He was wounded at Busaco, and he was among the first who mounted the breach at the storming of Badajoz. Having been promoted to the rank of lieutenant-colonel, he attended the Duke of Wellington as aide-de-camp at Waterloo, where he lost his right arm; and in consequence of his military services he was made a K.C.B. and a colonel in the army. In 1814 he was made aide-de-camp to the Duke of Wellington, and the following year was appointed aide-de-camp to the French embassy at Paris, and so great was the confidence reposed in him that he remained in that city as minister plenipotentiary ad interim from the following January to March. He continued to act as secretary to the embassy at Paris until 1816, when he was appointed Master of the Ordnance andarrivée of Fitzroy Somerset to the rank of full general. He left England in March 1854, and after spending some months at Varna and Constantinople, during which time the army suffered very severely from sickness, he landed on the Black Sea, and joined the army in the Crimea. In conjunction with Marshal St. Arnaud, who commanded the forces of our French allies, he fought the battle of the Alma on the 30th of that month. It has been stated that he wished to attempt carrying Sebastopol by a coup-de-main, but this not being agreed to by his colleague, it was determined that it should be invested. Unfortunately, the siege proved one of longer duration than either of the generals had calculated. Difficulties in furnishing provisions and clothing for the troops, which appear to have lasted for a long time but feebly attempted to be overcome, resulted in a large portion of both the English and French troops perishing in the trenches before Sebastopol during the subsequent winter, 1854-55. The failure of more than one assault upon that city, the difficulties experienced by our troops in the sufferings he felt most tenderly, together with the censure of the English press upon his line of conduct, unhappily increased the symptoms of diarrhoea, by which he was attacked in the following June, and he died in camp before Sebastopol on the 28th of next month, leaving behind him the memory of an able and brave soldier and a general of high ability, who commanded at once the confidence and respect of his men.

The general orders issued by the commander-in-chief at home, as well as those issued by him, were divided command over the allied troops in the Crimea, bore testimony to his great and important services. His body was carried back to England, and interred in the church of Badminton, Gloucestershire. A life pension of 10000 a year was secured to his widow, and the children of a son who succeeded him in his title. He married, in 1814, Harriet, daughter of the third earl of Mornington, and niece...
of the Duke of Wellington, by whom he left two daughters and an only son, Richard Henry Fitzroy, now second Lord Raglan, who was formerly in the civil service at Ceylon, and afterwards held the post of Resident at Jaffna. His eldest son, a lieutenanit in the army, was killed in the first Punjab campaign, while serving on the staff of Lord Gough, in December 1845.

RAIANIA, a genus of Plants so called in honour of the great botanist, John Ray, is known by the staminiferous flowers having a bell-shaped perianth in six deep oblong pointed segments, most spreading in their upper part. Corolla none; stamens with six filaments, bristle-shaped, shorter than the calyx; anthers simple. Pistillate flowers, the perianth bell-shaped, in six deep segments, permanent, withering; corolla none; pistil with the germen inferior, compressed, with a prominent border at one side, 3-celled; styles 3, the length of the calyx; stigmata obtuse; carpel innumerable, of three cells without valves, crowned by the calyx; two of the cells barren, almost obliterated, without wings; the third fertile, compressed, extended into a very large half orbamental wing; seed solitary, nearly elliptical, compressed.

R. hastata, Halberd-Leaved Raiania, is found in the island of St. Domingo. The root is perennial, sometimes large and ovate, sometimes 4 or 5 inches long and 3 inches thick, round at each end. Its substance resembles that of a redish without any strong pungent smell; the bark white or yellow-coloured, little tough and warty, the flesh very white, tasting like a bean. The flowers small, whitish, in simple axillary drooping clusters.

R. cordata, Heart-Leaved Raiania, has ovate leaves somewhat heart-shaped at the base, 7-ribbed. It is a native of the West Indies, from whence it was sent to Kew Gardens in 1786, by Mr. Alexander Anderson. Plimmer represents the habit of the root, stem, &c., much like the foregoing; but the leaves are regularly ovate, pointed, more or less heart-shaped at their base, and furnished with seven ribs continued from that part to the point. These ribs are connected by numerous transverse veins.

R. ovata, Oval-Leaved Raiania; has ovate-pointed 3-ribbed leaves, the margins of the bills of St. Domingo, and has a shrubby stem, turning thread-shaped, sub-divided with slender smooth leafy branches. The leaves rather distant, stalked, smooth on both sides, pointed, entire, 3-ribbed, being ovate at the base. The flowers numerous, the males in compound clusters, females in simple ones; all stalked and turned toward one side. Corolla very minute, yellowish-green in the male, reddish in the female blossoms.

R. angustifoia, Narrow-Leaved Raiania, is a native of the western part of St. Domingo, where it climbs upon high trees, flowering in May.

R. quinata, Five-Leaved Umbellate Raiania, has five leaves on a common stalk. It was observed by Thumbel at Hiroshahi and Nagasaki, and in Japan, growing in a wall and in parks. The stem is round, smooth, yellow-coloured, and branched. Leaves several together, axillary, stalked, smooth. Flowers in umbels from the same buds as the leaves, on slender stalks, as long as the footstalks.

R. heterophyllum, Six-Leaved Clustered Raiania. Leaves six, on a common stalk, oblong-acute. Flowers racemose. It is a native of the country of Fakonie, in Japan, among bushes, flowering in April. The stem is round, striated, smooth, climbing. The flowers in axillary racemes, clusters sub-umbellate, differ from R. quinata in having mostly six leaves on a stalk, which are acute, reticulated, with veins at the back, and larger than in that species. The flowers moreover grow in clusters, not in umbels, in a sub-umbellate form. D.E., or RAINIA, a sub-order, or family of Plagiostomous Cartilaginous Fishes, of which the Common Ray is the type. The body of these fishes is horizontally flattened, and more or less discous; the dorsal fins are mostly placed on the back, the pectoral and caudal, called pectoral-pair, arise from the nasal part of the skull, and extend towards or meets the anterior part of the crest or pectoral fin; the branchial openings are inferior.

This sub-order is divided into the following families or tribes:

1. Cephalopteridae, Horned Rays.—They have a muzzle distinguished by two horn-like processes; the mouth before or beneath very broad; teeth very small, in some wanting in upper jaw; tail long or longer than the body, with a conical spine, and a dark line on the flanks. The genus Cephalopterus has large lateral eyes and a transverse mouth, with small teeth like a file.

C. giuranis is the only species known in the European seas. A specimen of this fish was once taken on the southern coast of the British Isles, and has been reported as taken on the coast of Nice. It approaches the shore, and is most frequently taken in the month of July. In Italy the small ones are called Vachetta, and the larger ones Vacuna. It dies immediately on being taken out of the water.

2. Myliobatis, Eagle Rays.—The head is partially disengaged from the body; mouth large, with tooth-like vertiads wanting; tail long, with a back-fin on root and a serrated sting behind. The genus Myliobatis has flat teeth; the central plate much longer than those which are lateral; pectoral fins wing-like; the tail armed with a spine on the root, behind that a serrated one.

M. aquila, the Whip Ray, the Eagle Ray, and the Muller. This fish, though rare, has been found on the British coasts.

3. Trygonida, the Sting Rays.—The head is laterally inclosed by the pectorals; the teeth transversely elliptical; the tail without any fin, or merely a low vertical curricular hair. The teeth are more or less sharp and serrated, oval.

The genus Trygon has the characters of the family.

T. pastinaca, the Common Trygon, the Sting-Ray, the Fire FiUare, La Pastinque of the French, is an example of this family. It was well-known in the ancient and older literature with regard to the venom of the spines of these fish. It is not unfrequent on the British coasts. The powerful serrated spine on its tail is used as an organ of defence.

5. Raja, the Skates.—The body is rhomboidal; tail depressed, slender, generally with a low terminal fin, and frequently with rows of small spines; skin smooth or with small curved prickles; teeth flat, pavement-like, and pointed in the mouth as in spawners. The skin of this skate is covered with two small fins near the end of the tail; the eyes and temporal orifices are on the upper surface of the head; the nostril, mouth, and branchial apertures beneath. The Skates are very numerous on the British coasts, and some of the species are used as food. The young are deposited in a similar manner to the sharks, in their horny cases of a square form, with four projecting horns, giving them the form of a butcher's tray. These cases are very frequent in the sea during the spawning time. The genus Aspius has two small fins near the end of the tail; the eyes and temporal orifices are on the upper surface of the head; the nostril, mouth, and branchial apertures beneath.

RAI 565 RAI

R. radiata, Starry Ray. — A rare species.

6. Torpedoidea, the Torpedoes. — The head is very large and surrounded by pectorals, so as to form a circular disc; the tail is short, feebly, depressed at the base, cylindrical at the extremity; mouth beneath; teeth pointed or flat. These fish are many of them remarkable for their power of giving electric shocks; there are two species of Torpedo found on the British coasts.

Torpedo vulgaris, the Old British Torpedo, the Common Cramp-Fish, the Numb-Fish, the Electric Ray, and the Cramp-Ray. This fish is only occasionally found on our coasts.

T. nobiliana, the New British Torpedo. This is identical with the Torpedo of the Mediterranean.

7. Rhinobatos, the Beaked Rays, have the maxilla generally single, and the pelvis being united in the male; the young are born round or elliptical, in some broader than long, and often on summits of undulations; body smooth; caudal fin bicipital, or cut obliquely, forming one lobe, and two of these fishes connect the Skaros and Rays. The species inhabit the Mediterranean, the Atlantic, and the coasts of Brazil. They are not found on the coasts of Britain.

8. Pristida, Saw Fishes. — The snout is produced into a long flat cumin saw-shaped blade, with teeth on the lateral edges. The western Rhinobatids are very similar, and generally the skin is slightly ruffled; skin with very small, flat, roundish, or 6-cornered scales; mouth beneath.

(A. Adams, Baitte, and Barron, Manual of Natural History; Year Book for the British Fishes.)

RAILWAYS. — The first line to which an account was brought in the 'Penny Cyclopedia,' article Railway, vol. xii., and Trans, S. 1., no material alteration has been made in the method, and some account of the peculiar construction of some of their works, the general form of the cars of Bruxelles. There have been no new trunk lines undertaken, unless the North Kent be considered such, but the construction of branches and connecting lines has been pursued uninterruptedly; and there is now no important town in the United Kingdom which is not connected by a railway system, if not directly, at least by a short transit by means of omnibuses or other public conveyances. The legislation, therefore, has been principally as to deviations, connecting branches, the throwing of some of their lines, the granting of powers for amalgamation, for the purchase or leasing of constructed branches, and a few of the acts passed were for railways in the East Indies and the colonies. In 1846 there were passed 272 railway acts, 184 in 1847, 83 in 1848, 35 in 1849, 30 in 1850. In 1850, in June, were opened 6297 miles open in the United Kingdom, of which 891 miles were in Scotland, and 515 miles in Ireland, and the capital which had been authorised by parliament to be raised was 356,055,115l, of which 232,085,154l. had been paid; 52,063,154l. by way of loan; and 51,904,047l. had been paid in the year on shares, and 7,967,046l. had been raised by loan. During the year 72,648,242 passengers were conveyed by railway. In 1851 there were 61 railway acts passed, amounting to 92 in 1852, 69 in 1853, 82 in 1854, 76 in 1855, 60 in 1856, and 84 in 1857.

On Dec. 31, 1856, there were in the United Kingdom 8710 miles of railway open for public traffic; there were 10,650 miles in course of construction; and there were 2351 additional miles authorised, which had not been commenced at that date. On Dec. 31, 1857, there were 9091 miles open. The total amount of capital and loans authorised to be raised up to Dec. 31, 1856, was 777,777,507l., of which 307,894,086l. had been raised; the expenditure incurred through railway branches and works amounted to 52,329,419l., of which 25,008,901l. was in England and Wales, 13,397,128l. in Scotland, and 7,819,431l. in Ireland. During the year, 27 passengers had been killed, and 286 injured. The total number of accidents had been 281 killed, and 394 injured.

In the year 1857 the number of accidents had materially increased; there was the continuation of French railways and the opening of the line to Paris, 231,475, and the receipts for the conveyance of goods, cattle, minerals, parcels, &c., amounted to 13,011,748l. Of the goods traffic, 7,062,379l. were for the carriage of 23,833,031 tons of merchandise, 3,688,964l. for the carriage of 40,395,675 tons of merchandise, 3,127,001l. for the conveyance of 10,450,175 head of live stock, and 1,225,829l. for the carriage of parcels, &c. In England and Wales the receipts averaged 3190l. per mile, in Scotland 3092l., in Ireland 1094l. per mile; the average working expenses were reduced to 1270l., or 60s. per mile, in the United Kingdom of having eight or nine thousand miles of railway open, it is of yet more importance to society at large that the other countries of the civilised world should be similarly provided; that prejudice of race and of creed should be softened down by intercommunication; and that each country should benefit from the produce of the others by interchange. It is no inconceivable a fact in the world's history that the Magyars of Hungary, the Slavonian of Russia, the Dutch of the Low Countries, and the French of France and Italy, should now be travelling in the same way, with locomotives displaying the same kind of highly-finised mechanism, as the inhabitants of the more developed and commercial countries of Europe. We have yet to see whether European railways will form a chain of roads from one to another, so long as this is not the case, a railway line must inevitably be a line of civilisation. It is a "great fact" that a man may now 'book through' from London to so many continental cities as Paris, Brussels, and Barcelona, and a line from Brussels to the French frontier at Quierne, making a total of about 247 English miles; in 1837 further lines were sanctioned from Ghent to Courtray, Courtray to Tourna, Braine-le-Comte to Namur, and Landen to St. Frond—a further distance of 94 miles; these various lines were opened to Brussels in 1835, to Antwerp in '36, to Ghent in '37, to Ostend in '38, to Courtray in '39, to Tabwez in '40, to Mons in '41, to the French frontier in '43, and on the 31st of December last the 341 miles were opened; and these had cost 4,114,354l., or about 12,600l. per mile, exclusive of stations and carrying stock, which raised the cost to 16,500l. per mile. The Belgian lines open in 1856 were, from Ostend to Brussels, 91 miles; from Brussels to Mons, 77 miles; from Mons to Quierne, 50 miles; and from Quierne to Paris, 162 miles; from Brussels to the French frontier at Quierne, 50 miles; and from Mons to Quierne, 9 miles; from Brussels, by Malines and Liége to Herbeisol, which it joins the Prussian line to Aixe-la-Chapelle, 96 miles; from Landen to St. Frond, also joining the line to Aixe-la-Chapelle, 36 miles; from Bruges to Poperinge, joining a line to Calais, 59 miles; from Brussels to Mossen, connected with the line from Lille to Paris, 73 miles; from Brussels to Antwerp, 26 miles; from Ghent, 27 miles; from Mons to Quierne, 162 miles; from Brussels to Antwerp, 26 miles; from Ghent, 27 miles; from Brussels to Bazel, 51 miles; from Brussels, by Namur, to Verliers, joining the Aixe-la-Chapelle line, 65 miles; from Brussels to Ebelines, the direct Paris line, 65 miles; from Brussels to Namur, by Braine-le-Comte and Charleroi, 60 miles; from Louvain to Charleroi, by Wavre, 41 miles; from Brussels to Antwerp, 39 miles; from Namur to Wavre, 25 miles; from Wavre to Mons, 15 miles; and from Mons to Quierne, 90 miles. The Great Luxembourg line, of which only parts are completed, is to join the other lines by rail, and then by the lines from Paris to Nancy, Strasbourg, Cologne, and Mannheim. It is at present only open as far as Namur, though the works are nearly completed as far as Arlon. The Great Luxembourg line, when finished, will form an important link in the chain of communication from England to the centre and south-east of Europe.

The portion of this railway system near Liége required very heavy works; but the average character has been easier
In some cases, private enterprise has come to the aid of the Government and, instead of railways being formed from Paris to Versailles; and one or both of these are to form parts of the route to Brest. Another company formed the Boulogne and Amiens line, which works in harmony with the State line from Amiens to Paris, and the Paris and Orleans railway has a branch from Havre, and a branch made to Dieppe. The Paris and Orleans railway, made by a private company, has been adopted as the commencing portion of both the State lines to the Spanish frontier.

The position of France relatively to neighbouring countries, renders its system of State railways one of considerable importance. England, of course, has no other connexion with it than through the medium of the ports of Calais and Dunkirk, and the ports on the northern line; Havre, have railway communication with Paris. Nantes, near the mouth of the Loire, has a continuous railway route of about 270 miles to Paris. The Bordeaux line has been opened from Paris; but everything beyond Bordeaux, towards the Spanish frontier, is only yet in process of formation. The railway down southward, through the centre of France, has two branches, one of which is completed to Limoges, and is to be carried on to Bordeaux; the other goes by way of Tournon and Givors, and to Marseilles. The connection with Lyon, Tournon, and Alba, and the Belgian railway from Marseilles is open throughout its whole length. The Strasburg line has been opened throughout from Paris to the Rhine—a very important route in respect to the intercommunication between France and Germany. In the Western provinces, which are now rather thickly congregated; for not only is the traffic with England and Belgium important, but there is considerable mineral wealth in the district near the Belgian frontier. France, as a whole, has very few cross lines of railway; nearly all of them radiate from Paris as a centre.

Before noticing the railways of Germany, it may be well to say a few words concerning the thinly inhabited countries to the north, such as Denmark, Norway, and Sweden. The trade in those countries is comparatively small, and capital scarce, there has hitherto been neither a strong inducement nor a practical power to construct railways. But English capital has lately begun to flow thither for these purposes. The Danes have made for themselves a short railway of about 17 miles from Copenhagen to Roskilde, in the busiest part of the kingdom; but all the other railway projects, both in Denmark and in Norway, are connected with English enterprise. The attempt to establish a steamboat route from Lowestoft to Denmark, will be nugatory unless aided by the formation of railways; and many surveys have since been made in Holstein, Schleswig, and Jutland, to determine on the feasibility of such constructions. Germany has also a line, which separate Copenhagen from the German Ocean. In Holstein itself, which is Danish in ownership but German in feeling, there is a railway open from Antona to Kiel, with branches to Rendsburg and Glückstadt; but no railways have yet been opened in the more northern provinces of continental Denmark. A railway of 43 miles in length, from Töningan to Flensburg, one on the west and the other on the east coast of Schleswig, establishes a route from the German Ocean to the Baltic, and one 56 miles in length, also opened from Copenhagen to Cörsör. Other routes will very probably be determined on before any long time has elapsed, for surveys have been made, or are being made, from Flensburg to Rendsburg, and from Copenhagen to Kiel; and many of these lines are at the very time when Copenhagen may possibly be brought within two days' journey of London.

With respect to Sweden, nothing (that we are aware of) has been effected towards railroads in the lake-covered country, except two short lines from Örebro to Arbog, and from Örebro to Nora, the two not much exceeding 40 miles; but a prospectus has been issued relating to a Swedish company, whose operations will be sanctioned by the Government. One of the lines is from Stockholm to Göteborg, 350 miles in length, which will connect the Baltic with the German Ocean or North Sea. Norway, too, has made a beginning. An English company has made a connexion to Christiania, which has been extended to Mõßen; the former town is the capital, and near the sea coast; while Mõßen is in a lake connected with the extensive inland navigation of the eastern part of Norway. At pre-
sent this is only completed as far as Eidsvold, a distance of 48 miles.

In the wide-spread region to which the general name of Germany is applied—as extending as it does from the confines of Denmark in the north to those of Italy in the south; from the North Sea to the Rhine in the west, and from the Black Sea to the Baltic in the east—the construction of railways must necessarily be very unequally distributed, arising from the great diversities in population and commercial industry. There is, however, considerably of the central and important area of Europe which has been developed. Some of the railways have been constructed by the respective governments, and others by private companies. Nearly the whole of the territory in the Austrian empire, in Bavaria, in Württemberg, in Hanover, in Brunswick, and in Hesse, has already been opened up; and in Prussia, the construction of the railroads, which it has been moulded by companies have in most cases been redeemed or purchased by the state—so unwilling are most of the states to allow the control of locomotion to slip out of their hands. In Prussia, and in a few of the other states, the government has abstained from any direct interference with the construction or working of the railways; it has rather lent a fostering hand to private companies, in cases where the traffic did not appear to be large enough to pay an adequate dividend on the outlay. In order to keep down the expenditure to a reasonable limit, all costly works are avoided unless absolutely necessary; hilly districts are traversed by steep inclines and numerous curves, instead of by costly tunnels, cuttings, viaducts, and embankments; inasmuch as a slower rate of travel and more frequent stops are found in England renders such gradients and curves easily manageable.

Taking Germany in its widest sense, as including the Austrian empire as well as the various states north and west of Berlin, there is, that from Frankfurt to Berlin, a distance of 1500 miles of railway, in 1847 about 2800 miles, and by the end of 1849 about 4500 miles. At the last named date there were also 800 miles more in progress of construction, and about 3100 miles either decided on or contemplated, but without having been commenced; making a total, real and projected, of about 8450 miles. Prussia, with the Rhine states, possesses the larger portion, forming a net-work connecting them with France, Belgium, Bavaria, Austria, and Russia, and they show a great desire to extend their lines further eastward of the German empire, in the direction of Poland and Russia. Scandinavia is also seen to be becoming a railway empire, with a line from Copenhagen to Stockholm, and another to the Russian frontier. The kingdom of Hanover has a railway from Hamburg to Zerbst, and a branch from Hildesheim to Braunschweig. A line from Strassburg to Aix-la-Chapelle, and another from Strassburg to Mannheim and Heidelberg, are under construction. A railway from Hamburg to the Baltic, and another from Berlin to the River Elbe, are under consideration.

Of the countries lying south of the Alps, and west of the Pyrenees, little can yet be expected in respect to railway enterprise; the great foundation of the Alp line from France, Switzerland, and Austria, and Switzerland itself being surrounded by the Alps. Nevertheless Switzerland has not been inactive to the subject. There are now open lines from Basel to Lucerne and Interlaken, and from Lucerne to Lucerne, and from Lucerne to the Black Sea. There are also lines planned from St. Petersburg to Cracow, from St. Petersburg to Baltischport in Esthonia. The railway from Warsaw to Cracow is open, as also the line from Cracow to Warsaw, but in the other districts mentioned above, the work, so far as commenced at all, are proceeding slowly.

The railway from Warsaw to Cracow is open, as also the line from Cracow to Warsaw, but in the other districts mentioned above, the work, so far as commenced at all, are proceeding slowly.

In the vast Russian empire, the first attempt to obtain railways was made by offering great advantages to any capitalist who would establish companies for this purpose; they were to have a gratuitous grant of all the land necessary, and all the timber and raw material which they might find necessary; a subsidy of 300,000 roubles per mile; and a permanent stock free of duty; they were guaranteed by the Emperor a minimum dividend of four per cent. on their capital; and the great land-owners offered the use of their serfs in constructing the roads. The first railway to be planned was from St. Petersburg to Moscow, about 680 miles. A goods railway, worked by horses, about 100 miles in length, has been formed to connect the Don with the Volga. There is a railway from St. Petersburg through a place near it called Tsarsko-soelo to Luga, about 84 miles. This is a part of the Warsaw line. Tsarsko-soelo has a royal residence, and between it and St. Petersburg there is a busy traffic, somewhat akin to that of our Greenwich railway, or to the Varesilles railway near Paris. Southern Russia is to have a railway from Odessa to Kief, to be commenced in a little time, and another from Odessa to Monastyr, and another from Odessa to the Black Sea. There are also lines planned from St. Petersburg to Cronstadt, and St. Petersburg to Baltischport in Esthonia. The railway from Warsaw to Cracow is open, as also the line from Cracow to Warsaw, but in the other districts mentioned above, the work, so far as commenced at all, are proceeding slowly.

In Italy, distracted as it is by political disputes, and broken up into small states and republics, the railway enterprise has been much retarded. Down to the year 1845, nothing had been done towards establishing international railways from state to state; but each state, or at least three of them, have now short lines confined to their own territories. In Tuscany, there are lines from Lucca to Pisano, Florence to Sienna, Pisa to Livorno, and Florence to Prato; and in Naples the lines extend from Naples to Cava, and from Naples to Capua; from Rome a line of 12 miles is open from Roma to Frascati, and other works are in progress. In Austria, the plans of the year 1850, nothing had been done towards establishing international railways from state to state; but each state, or at least three of them, have now short lines confined to their own territories. In Tuscany, there are lines from Lucca to Pisano, Florence to Sienna, Pisa to Livorno, and Florence to Prato; and in Naples the lines extend from Naples to Cava, and from Naples to Capua; from Rome a line of 12 miles is open from Roma to Frascati, and other works are in progress. Spain and Portugal have always been much isolated from the rest of Europe by the formidable Pyrenean barrier; and, from various causes, they have been slow to adopt the canal and railway systems which have so valuable to the rest of Europe. The main line from Madrid to Alarcones in Murcia, 174 miles, which it is proposed to continue to Zaragoza and Alicante. The other lines are from Barcelona to Arenys del Mar, from Barcelona to Granollers, from Barcelona to Martorell, from Barcelona to Reus, from Barcelona to Tarragona, from Barcelona to Reus, from Reus to La Jonquera, from Reus to St. Raphael, from Reus to Tarragona, from Reus to Valencia, from Reus to Cadi, from Cadi to Xeres (or Jerez) de la Frontera; and from Valencia to Alcudia; all of them short lines, the length of the longest being only 38 miles. Portugal has but one railway, under 30 miles in length, from Lisbon to Vicedos. The Mohammedan, imitating the European in so many things, is now imitating him in railway enterprise. The Pachas of Egypt, eager to do all that can be done for facilitating the overland route to India, is now having a railway constructed from Alexandria towards Cairo, to touch the Nile at a point which will get rid of the slow transit along the canal from Alexandria, and thence to extend to Cairo. The crossing of the desert itself to Suez, whether from Cairo or from some port in the Mediterranean, has been very amply discussed for several years past; schemes for ship-canaals and railways have been brought forward in considerable numbers, and speculation in railway shares has been great; and there is not at the present time, so far as we are aware, any strong probability that either a canal or a railway over the Isthmus will be constructed.

In India itself much has been done, and much more is in progress. A number of railways have been opened, and 1100 in progress, to connect it with Delhi. But the terminus at Delhi, in consequence of the recent rebellion in India, it is now said, is to be changed, and that the railway is to be run by Allahabad to Umarkot, which is to be made the capital of north-western India. From Bombay lines are to run to Mirzaapore, where it will join the Calcutta line to Delhi, to Madras, and to Ahmedabad; on the first 49 miles, and on the second 71 miles, have been opened, but the remainder of the line, both in the distance and in progress, on the two lines; on the third nothing is opened, but the earth-works are completed from Surat to Ahmedabad, 150 miles. From Madras a line is laid out to the western coast of the peninsula, of which 90 miles are open, and 300 are in progress; and from Madras to Bellary, 596 miles are in progress of construction. [INDIAN EMPIRE, p. 230, &c.]

In the United States of America, as early as 1843, we find that there had been more than 5000 miles of railway constructed, belonging to 143 companies, an average of only 36 miles as the length of each railway. The railways were constructed, as in England, by joint-stock companies, and the bondholders in each State were entitled to the proceeds of each railway was constructed mainly for local traffic, and still, nevertheless, it afforded a line of communication, by juncions of various lines. American railways have been constructed very much more cheaply than those in England, partly because the legal and legislative expenses are extremely small, partly because the land is bought at a low price, partly because timber is very cheap, partly because no useless expenditure is bestowed upon splendid stations, partly because the relatively low speed of travelling enables steep inclines and tight curves to be worked safely. The eight great arteries of communication were,—1st, parallel to the sea-coast, throughout the whole vast distance from New England to Florida; 2nd, east and west from Boston to Lake Erie; 3rd, New York to Lake Erie; 4th, Philadelphia to Lake Erie; 5th, Philadelphia to Pittsburg, over the Alleghany Mountains, and comprising a system of railways and canals; 6th, Baltimore to the Ohio; 7th, Boston to Cincinnati, uniting the Atlantic with the Ohio; 8th, Great Western to St. Louis. All these routes were actually completed in 1843, but that sufficient had been done to show that such routes would result from the united labours of many companies influenced primarily by local interests, and that the whole had increased to 6500 miles. The Atlantic States, thickly inhabited and commercially active, were naturally those in which railways were formed earliest and in greatest number; but the system gradually extended to the vast agricultural districts of the west; inasmuch that by 1849 there were five short railways in the state of Mississippi, ten in Louisiana, and a few in Alabama, Illinois, Michigan, Indiana, and Ohio. Dr. Lardner describes the utter strangeness of the sights and sounds presented by this encroachment of civilisation on the negro's forest home. 'In the moonlight the negro and the whiteman, both dressed in cabins, drift past the forest and the prairie. "Traveling in the back woods of Mississippi, through native forests where, till within a few years, human foot never trod, through solitudes the stillness of which was never broken by a sound, there is the hiss of the red man, I have heard my own shrill, hollow voice, followed by a train of steam, shot by an engine driven by an artisan from Liverpool, and whirled at the rate of twenty miles an hour by the highest refinements of the art of locomotion. It is not easy to describe the sensation impressed on the indolent red man from its lair at the earring of the ponderous machine, and the appearance of the snake-like train which follows it."'—Railway Economy.

Of the 6500 miles of railway at work in the United States in 1849, more than half were in New York, Pennsylvania, and the New England States. Of these, the most remarkable, perhaps, is that which traverses Pennsylvania from east to west, as part of the route from Philadelphia to Pittsburg. First there are 61 miles from Philadelphia to Columbia on the Susquehanna. Then there are 175 miles of canal from Columbia to Hollidaysburg, which bring the traveller to the eastern base of the Alleghany Mountains. Next is the Portage railway of 37 miles, from Hollidaysburg on the Juniata to Altoona; thence the Alleghany branch of about 150 miles, which this railway has to climb a height of 1398 feet, and then descend 1172 feet; the trains are drawn up to the summit level by stationary engines and ropes; different levels being reached, one by one, by the aid of separate engines and ropes. From Altoona to Pittsburg there are 86 miles, and from there to New York the Portage Branch of the east to west is complete. This fourfold division of the route is not so troublesome as it would be in England; as by an ingenious contrivance, the canal-boats are made available for land travel, the boats, which are of considerable magnitude and length, are divided into segments or sub-boats, by partitions made transversely and at right angles to their length; so that each boat can be separated into two or more smaller boats. When the canal route is traversed, these several segments are joined together, and the whole is raised to the summit level; on the other hand, with the railway the reverse is done. The short stumpy boat thus forms a passenger carriage or a goods wagon on the railway; while three or four of them form a spacious boat on the canal.

By about the middle of the year 1851, it was seen that the railways in the United States were more than 10,000 miles in length, having cost about 67,000,000$; or 150,000,000£. The average price of the land purchased for right of way was stated to be 11,500, besides 11,300 in course of construction, making a total of little less than 33,000,000$. An estimate for 1853 gives 13,000,000 as the probable length in the east, and at the same time, that ten miles a year is an average of increase in the eastern railway traffic. In 1854 there were 17,317 miles complete, and 12,250 miles in course of construction. Since that period there has been a fall, and the chief lines undertook to have been in connection with those of Canada. In January 1857 there were open and in work 29,340 miles of railway in the United States, and a line of 40 miles in length from Aspinwall to Panama. Including Canada there were in January, 1858, 440 lines, but many of them form portions of large systems.
